The second attack occurred in 1935 and had lasted one month when the patient was first seen. Just prior to this attack he had been in Bellevue Hospital for twelve days for delirium tremens. The vision was 20/30 in each eye and there were a large cecocentral defect for a 5 mm red test object and a tiny paracentral scotoma for a 1 mm white test object at a distance of 1 meter. The vision improved to 20/25 in each eye after the first injection of acetylcholine and to

Of twenty-four patients treated with sodium nitrite intravenously, twenty-one (87.5 per cent) attained a final vision of 20/30 or better in at least one eye in an average time of eighteen and four-tenths days, and twelve (50 per cent) attained a vision of 20/20 in at least one eye in an average time of thirty days.¹

2 *Results in Eyes Improved*—In table 2 are tabulated the visions before and after treatment of the eyes which were improved with acetylcholine injected intramuscularly and with sodium nitrite injected intravenously. In table 3 the final visions are tabulated with reference to the time required for their attainment in both groups of cases.

A *Acetylcholine* Forty-one eyes were improved. Before treatment twenty-seven eyes (65.8 per cent) had vision of 20/70 or less. After treatment twenty-seven eyes (65.8 per cent) had vision of 20/30 or better. The average time of improvement per eye (forty-one eyes) was fifteen and three-tenths days. At the end of twenty-one days, twenty-seven eyes (65.8 per cent) had attained their best final vision and sixteen eyes (39 per cent) had vision of 20/30 or better.

B *Sodium Nitrite* Forty eyes were improved. Before treatment thirty-two eyes (80 per cent) had vision of 20/70 or less. After treatment thirty-five eyes (87.5 per cent) had vision of 20/30 or better. The average time of improvement per eye (40 eyes) was twenty-one days. At the end of twenty-one days,

15 The time in which a vision of 20/30 or better was attained in at least one eye was used as the basis for these calculations.

twenty-nine eyes (72.5 per cent) had attained their best final vision and twenty-four eyes (60 per cent) had vision of 20/30 or better

C In the last two columns of table 3 are given the combined statistics for eighty-one eyes (out of a total of eighty-eight eyes treated) which have been improved with vasodilator therapy

SUMMARY AND CONCLUSIONS

In cases of tobacco amblyopia without optic atrophy, the visual improvement obtained with intramuscular injections of acetylcholine chloride roughly paralleled that obtained with intravenous injections of sodium nitrite

Visual improvement was more rapid in the patients treated with acetylcholine, but it was greater in the patients treated with sodium nitrite

The visions of the individual eyes were on the whole more reduced before treatment (more eyes had vision of 20/70 or less) and were on the whole better after treatment (more eyes had vision of 20/30 or better) in the patients treated with sodium nitrite than in the patients treated with acetylcholine. For this reason it would seem that intravenous injections of sodium nitrite are more effective than intramuscular injections of acetylcholine chloride in the treatment of tobacco amblyopia

This slight but definite difference in potency is probably due to the fact that sodium nitrite is destroyed, inactivated or excreted by the body less rapidly than acetylcholine, so that its vasodilating effect is active for a longer time

The conclusion seems unavoidable that either sodium nitrite or acetylcholine, administered parenterally, brings about a more rapid return of vision in cases of tobacco amblyopia without optic atrophy than has been shown to occur in comparable series of cases as a result of treatment with time honored but relatively ineffective methods or drugs. This fact should lend additional support to the hypothesis that tobacco amblyopia is due primarily to a vascular spasm in the visual pathway

133 East Fifty-Eighth Street

ABSTRACT OF DISCUSSION

DR LAWRENCE T. POST, St. Louis The most important question involved in Dr. Duggan's paper is whether vasodilators are valuable in the treatment of tobacco amblyopia. The author and others have previously discussed the hypothesis that this disease is due to a vascular spasm in the visual pathway and the effect of vasodilators on shortening the time of return to normal in these cases, but I think these points are still unproved. Several speculations regarding the possible value of vasodilators in treatment of tobacco amblyopia occur to me. If it is assumed that the symptoms are produced by a very prolonged constriction of the blood supply of the visual apparatus, does it necessarily follow that relief from this constriction, if obtainable, would restore normal function? In diseases involving constriction of the peripheral vascular system of the extremities, though dilatation of the vessels of the extremities can be caused by sodium nitrite or acetylcholine, this does not help the disease condition. But more fundamental than this is the lack of proof that these vasodilators do actually increase the vascular bed of the visual system. There is considerable evidence that they do not dilate the vessels of the retina. Another theoretical point against the likelihood of this therapy being very valuable in treatment of a relatively chronic or at least nonacute condition is the evanescent action of these vasodilators. At most they probably act only a few moments and in the author's cases they have been used only once a day. In a previous paper the author, in considering the action of acetylcholine, has remarked on this transitory nature of their action and he referred to the fact that the action is much prolonged in the presence of physo-

stigmine even in very small quantities, and one of the authors, whom he quotes, used physostigmine as a preliminary to acetylcholine. Since it is reasonable to assume that a prolongation of action is desirable, this combination might be useful. In the medical service at Washington University, acetyl beta methyl choline has been found to have a much longer action than acetylcholine and is being used in preference to the latter drug. It is suggested that, if vasodilators are proved to be valuable in tobacco amblyopia, this drug might be found advantageous. The possibility of improvement by vasodilators must be further considered, but other factors that might be important in quick recovery should be carefully sought.

DR ARTHUR M. YUDKIN, New Haven, Conn. It is not worthy that two distinct types of therapeutic measures should be offered at this meeting for the cure of the same ocular disturbance. Tobacco alcohol amblyopia has been cured by other methods. One in particular is to eliminate the consumption of alcohol and tobacco and give the patient a well balanced diet. This method does not restore vision until the patient has adhered to the regulations for many months. At the Milwaukee session of the American Medical Association in 1933 I recommended the treatment of this disease on the basis of a well balanced diet supplemented by cod liver oil, and in some instances vitamin B complex was also given. Most of the patients improved even though they consumed a moderate amount of alcohol and tobacco. When destruction of the nerve was present, it was difficult to restore vision. Frequently a constitutional disturbance, such as diabetes, delayed the healing process. The author has presented a similar observation. From experimental work, it can readily be seen why one type of symptoms appears in one group of animals and another type in still another. Dr. Cowgill and his collaborators kept one group of dogs on a minimum amount of vitamin B (G), while another group was deprived of B₂ (G) entirely. The first group developed collapse, whereas the latter group suffered eventually from an ataxia. Two quite different syndromes were observed. The picture of complete deprivation was different from that of what might be called subnutrition. That is probably why in one group beri appears, in another pellagra, and in still another ocular disturbance. It becomes evident that an individual suffering from a deficiency may at some time or other have different nerves involved. In dealing with man, it must not be forgotten that the intestinal tract plays a great role in the distribution of materials necessary for the upkeep of the body. The strains of modern life have produced certain nerve manifestations that have actually upset the whole gastro-intestinal mechanism, with the result that the food is not properly prepared for digestion and absorption. I recommend that the eye doctor not only treat his cases with local medication but become interested in the general health of his patient. If the ophthalmologist is confident of his medical judgment, there is no reason why he should not advise the patient concerning diet and mode of living. Excellent results may be obtained in this ocular disturbance, which, I believe, is associated with a dietary deficiency, probably of a gastro-intestinal nature, by the restriction of alcohol and tobacco, by the elimination of constitutional complications and by prescribing a sensible, well balanced diet supplemented with moderate doses of standardized brewers' yeast and properly assayed cod liver oil.

DR WALTER F. DUGGAN, New York. It has been my practice with these cases, before and during treatment, to obtain the very best vision possible. By pointing out letters on the chart, instead of 8/200 or 10/200, one often can get a vision of 20/100 or 20/70. No case was considered as improved unless any improvement that was obtained was maintained at following visits. The charts have been changed so that the patients cannot memorize them. Also, since patients have noted that after any period of physical stress their vision seems to decrease, it has been my custom to allow the patients to rest a short time before the vision is tested. Some of these patients were seen every day. With improvement in the vision there is a very definite decrease in the size of the scotoma. Often patients say their vision is improving and while the visual acuity may be the same, the scotoma will be found to be definitely smaller. An analogous case which I saw with Dr. Knapp, was one of spasm of a branch of the central retinal artery in which the spasm with a field defect, had lasted for

two months. The spasm suddenly disappeared one night, and the patient came in a few days later with a greatly improved field and visual acuity. I know that reports have appeared stating that vasodilators do not dilate the retinal vessels. In the first place, I do not think the retinal vessels are involved in tobacco amblyopia. Also, if the retinal arteries are of approximately normal size, any slight increase in diameter would not be apparent. I have seen very constricted retinal arteries dilate with this treatment. The vascular bed must be increased because, in two or three cases which I had, there was a very definite fall in blood pressure, with intravenous sodium nitrite of from 20 to 40 mm of mercury, which was maintained for several hours. Acetylcholine acts only a few minutes on the blood pressure. The pressure will drop 10 or 20 mm and then be back to normal in fifteen or twenty minutes at the most. I think the use of physostigmine before acetylcholine would help.

DR FRANK D CARROLL, New York. The idea of Dr Duggan's that tobacco amblyopia is caused by a spasm of vessels supplying the optic pathway deserves critical consideration. There is some evidence that smoking constricts the peripheral vessels. A report published recently, however, indicates that there is no more peripheral vasoconstriction from smoking than there is from taking a deep inspiration of pure air. Several of my patients with toxic amblyopia who were heavy smokers have been tested by members of the Department of Pharmacology at Columbia University and no evidence was found by an accurate plethysmograph method of any peripheral vasoconstriction. But even if smoking does tend to constrict the peripheral vessels and raise the blood pressure, this does not indicate that either the cerebral or the retinal vessels are constricted. In fact, just the reverse is apt to be true. For example, when epinephrine is given, a vasoconstriction of the peripheral vessels occurs. This causes an increased blood pressure with a resulting vasodilatation of the cerebral vessels. Lambert has shown that, in animals, epinephrine, a peripheral vasoconstrictor, tends to cause a vasodilatation of the retinal vessels because of the increase in blood pressure. If there should be a spasm, where would it be and what would be its nature? It is almost certainly not in the retina; the retinal vessels appear perfectly normal in many of these patients. The pathologic change is essentially limited to the papillomacular bundles and therefore this hypothetical spasm would have to be limited to the vessels supplying the papillomacular bundle. The chief vessel supplying the papillomacular bundle is the central retinal artery, and when there is an ordinary spasm of this vessel it can be seen with an ophthalmoscope. It does not resemble anything seen in tobacco amblyopia. Moreover, this type of amblyopia comes on gradually and disappears gradually. Spasms of the central retinal artery or its branches that are familiar come on suddenly, therefore, we are expected to assume a very special kind of spasm foreign to our present knowledge. According to this vascular theory, my patients with this disease who are heavy drinkers would have been especially immune because they were heavy drinkers and should never have developed amblyopia—but they did. Vasodilators are suggested as being beneficial. One would expect a vasoconstrictor such as epinephrine to be of more value. This would raise the blood pressure and thus dilate the cerebral and retinal vessels as well as increase the rate of blood flow through the brain. The author maintains that the speed of recovery of patients receiving vasodilators is more rapid than in patients not receiving them. This is a difficult point to prove and needs controls. An attempt has been made to use other cases reported in the literature as controls, but they are not comparable. If the author is to persist in his efforts to prove the value of these drugs, he should treat every alternate case with an equal number of injections of saline solution or even vasoconstrictors.

DR DUGGAN. I have read most of the reports that Dr Carroll has read concerning the vasoconstrictive effect of smoking on the peripheral vessels and am amazed at the conflicting statements. I have treated with vasodilators alone some fifty cases of tobacco amblyopia without optic atrophy. The visual improvement has been so rapid in many cases that I have been surprised. Dr Fraich and Dr Bracken of New York have obtained good results. I have only the improvement in vision, the patient's word and the decrease in the size of the scotoma on which to base my figures. As to where the spasm

is located, Dr Carroll mentions that the papillomacular bundle is involved and that it is supplied by the central artery of the retina. It is, in the retina, but the central artery of the retina usually does not supply any fibers of the optic nerve posterior to the point at which it enters the optic nerve, and it certainly does not supply the papillomacular bundle in the chiasm. Behr recently mentioned that the central artery of the retina is strictly a retinal artery as soon as it enters the optic nerve. My feeling is that the arterioles which are involved are in the region of the chiasm, because of the bilateral field defects. I have seen no change, as a rule, in the retinal vessels after this treatment, but I have seen an improvement in vision and a decrease in the size of the scotoma. Tobacco amblyopia does not come on suddenly. Amblyopia does come on suddenly in retrobulbar neuritis, and I feel that this is much more analogous to a spasm of the central retinal artery than toxic amblyopia is. As to why these particular vessels are involved, I have no explanation other than that they are end arterioles. I think that Dr Carroll's cases and my cases belong to different groups. In the nine cases that he reported in December 1936, the average age was 36. The average age which has been found by all other authors in cases of tobacco amblyopia is between 50 and 56 years. Real cases of tobacco amblyopia do not show polyneuritis or symptoms of pellagra. The cases Dr Carroll reported do show symptoms of a deficiency disease. I think that he and I are discussing different disease entities.

COMBINED LIGATION AND INJECTION TREATMENT OF THE VARICOSED GREAT SAPHENOUS VEIN

C HARLAN JOHNSTON, M.D.

DES MOINES, IOWA

The ligation of varicose veins is not a new practice, nor is the high ligation of the long saphenous and injection of its distal end a new practice. Both these operations have been followed by recurrences of the veins, and as a result the strides toward perfection have brought about the present technic of high ligation, dissection of all the branches at this level and their ligation and section and the injection of the distal end of the saphenous vein. The latest technic is the culmination of all past attempts.

Ligation of the saphenous has been done since the days of Hippocrates. As time progressed the site of the ligation crept gradually upward, owing to the frequent recurrences of the varicose veins by the dilatation of collateral circulation. In 1896 Moore¹ of Australia recommended that the ligation be placed above any branches, but still he actually in practice made his incision 2 inches below that level.

John Homans² of Boston in 1916 picked the saphenofemoral junction as the ideal site for ligation and strongly recommended the tying off of all branches at that level as well. In spite of this suggestion by one of our most eminent surgeons, the ligation at lower levels continued and still continues to the present time, even when injection of the distal segment is combined with the ligation treatment and in spite of the fact that more ligations in certain cases are done at the present date than ever before. It is my purpose in this paper to show that the combined ligation-injection at the saphenofemoral junction together with the careful dissecting out and severing of all branches at that level offers the most satisfactory treatment, to date, in certain

Read before the Polk County Medical Society and Des Moines Academy of Medicine, March 30, 1937.

cases and promises the most in freedom from recurrence. The severing of the branches is stressed as being one of the most important factors in this operation.

ANATOMY

The course of the great saphenous vein is known, in general by most physicians and will therefore not be dwelt on to any extent. It is also known that it communicates through several branches with the deep

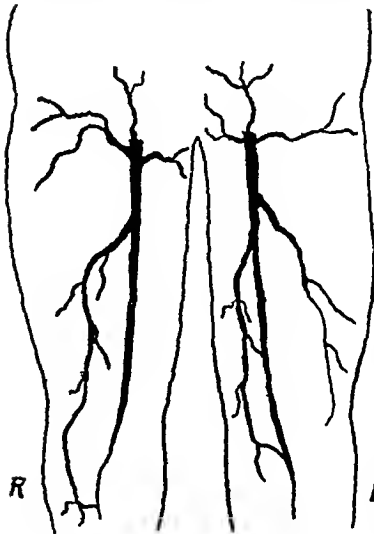

Fig 1—Collateral anastomoses shown in the right leg through the lateral superficial femoral vein and in the left leg through the medial superficial femoral vein.

system or femoral vein. Circulation normally is upward in both veins, but when the superficial great saphenous vein is varicose the blood runs downward, through the communicating veins and up the femoral. At the saphenofemoral junction, if the valves of the saphenous are incompetent it spills over and runs down again, thus establishing a vicious circle, and hence the ease of ulcer formation and the long healing time for bruises. The region is constantly

bathed in poorly nourished and poorly oxygenated blood.

Injection of such a vein can easily sclerose it and render it functionless. Such injections are placed in the vein all the distance up the thigh. Occasionally such an injection even in the lower part of the thigh may cause a creeping thrombus that gradually reaches the saphenofemoral junction. Such thrombi have in the past been the cause for much alarm but unless accompanied by some infection they have never led to embolic phenomena. The chief reason against closing such a vein by injection alone is that recurrence is too common. With the saphenofemoral valves incompetent there is a column of blood above that is hammering away at this thrombosed vein and soon will recanalize it. Ligation at the saphenofemoral junction and injection into the distal segment gives the next best treatment, but in time this weight of blood and the hammering away that accompanies respiratory effort or feats requiring strain will dilate the small branches at the junction and establish a collateral varicosity around the ligated stump and either back into the obliterated saphenous to recanalize it or connect to dilate a parallel system (figs 1 and 2).

Howard³ of Stanford University Clinics reports recurrence by recanalization in 100 per cent of such treated cases that he was able to observe twenty-nine months after treatment. However, in only 23 per cent had this recanalization gone to the extent of a return of varicosities. The other 77 per cent had recanalized in that period but had not yet dilated or caused a return of subjective symptoms. They were cosmetically and symptomatically cured but not cured to the satisfaction of the surgeon.

In figure 3 the five branches that are of utmost importance at this level are shown: (1) the superficial circumflex iliac vein, (2) the superficial inferior epigastric vein, (3) the superficial external pudendal vein, (4) the medial superficial femoral veins and (5) the lateral superficial femoral veins. At times not all these veins appear when dissection at the saphenofemoral junction is complete. At times they empty directly into the femoral instead of into the saphenous vein, at times they join the saphenous vein at lower levels, and at times some are absent entirely (fig 4).

TESTS FOR PATENCY

Before treatment is ever considered for any varicose vein, certain tests must be carried out. First a complete physical examination is done, including a urinalysis and a careful abdominal and pelvic examination—the latter in a search for possible obstructing tumors. Secondly the Perthes test to determine the patency of the deep femoral vein is done. This is easily performed by having the patient stand, applying a tourniquet above the knee tightly enough to cut off the superficial venous return and then having the patient walk the length of the room several times. If the deep venous return is not open he will experience pain very soon throughout the leg. If the deep system is open no pain will be felt and the dilated veins will tend to collapse. This collapse is due to the milking out of these veins by muscular contraction, which sucks or draws the blood through the communicating veins into the deep system and up the femoral vein. When one is uncertain with the results of this test, it is best to apply a tight bandage to the leg after it has been elevated and the superficial veins have been drained and then have the patient walk around the block two or three times. If no pain results the deep system is open, while if pain necessitates

removing the bandage it is closed.

When the deep venous return has been found to be open the next most important test is to see whether the arterial supply is sufficient. Pulsations are felt for in the dorsalis pedis and the tibialis posterior. In doubtful cases Samuel's test is made, wherein the leg is elevated to an angle of 45 degrees and the ankle is alternately flexed and extended while blanching of the plantar surface of the foot and pain in the calf are ascertained.

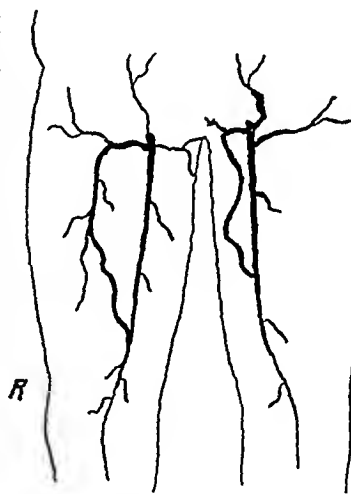

Fig 2—Collateral anastomoses shown in the right leg through the superficial circumflex iliac vein and in the left leg through the superficial external pudendal vein.

A more accurate test can be used if needed. This is the so-called histamine acid phosphate test as described by Sir Thomas Lewis of England.^{4b} If a 1,000 solution of histamine acid phosphate in physiological solution of sodium chloride is applied with a medicine dropper to the skin and six or seven punctures with a

fine hypodermic needle are made through it, within a few minutes the "triple response" can be observed. This consists of a small purple-red area, followed by a wheal and surrounded by a red flare around the puncture. This is the response of a normal person. The degree of the flare and the latent period of its appearance are the points to be observed and recorded. The

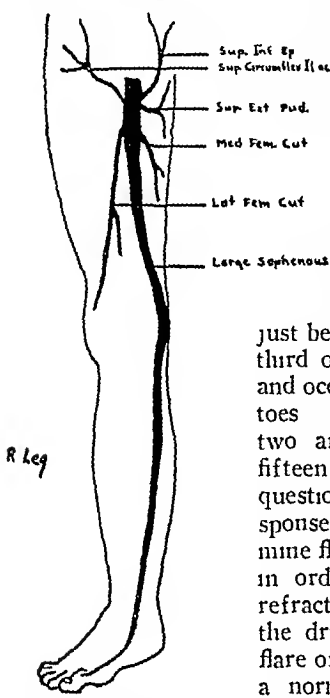

Fig 3—The five main venous branches at the saphenofemoral level

flare is caused by the dilatation of the small arterioles and is the result of a local nervous reflex. In arteriosclerotic or diabetic patients one sees a delayed or absent reaction. The reaction normally appears in two and a half minutes. The histamine flares are usually elicited above the knee,

just below the knee, at the middle third of the leg, above the ankle and occasionally at the base of the toes. Observations are made at two and a half, five, ten and fifteen minutes. If there is a question as to the normal response above the knee, a histamine flare is produced on the arm in order to rule out a general refractory state of the vessels to the drug. A delayed or absent flare on the leg in the presence of a normal reaction elsewhere is interpreted as an impairment of arterial flow. Such a test is made with the leg horizontal.

If arterial circulation is impaired in any degree, treatment of the varicose veins is contraindicated.

The question now arises as to just what veins should have this ligation treatment. In deciding this, two other tests are done. These are the Trendelenburg tests. With the patient lying on the operating table, the leg is elevated so that the vein drains out and a tourniquet is then applied above the knee. The patient is then asked to stand. If the veins fill quickly from below upward, it means that the valves of the communicating veins are incompetent and that the deep system is overflowing into the superficial. This is a Trendelenburg negative test. If one should release the tourniquet as soon as the patient stands up and the saphenous fills rapidly from above, it is a sign that the valves at the saphenofemoral opening are incompetent. This is called a Trendelenburg positive test. A combination of the two is called a Trendelenburg double test.

All cases presenting a Trendelenburg positive or a Trendelenburg double test are recommended for the ligation-injection treatment. This means all cases in which the saphenofemoral valves are incompetent. Such cases usually present large dilatations in the thigh but need not necessarily. At times the enlargements of the veins and the discomfort are entirely limited to the leg, and injection treatment alone, directed at that site, can at best give only temporary relief. There remains a column of blood above that will gradually increase in size and weight and will soon hammer out a new channel. Hence when one is confronted with a case presenting incompetent saphenofemoral valves, the treatment of choice is the ligation-injection treatment.

DETAILS OF THE OPERATION

After a study of many cadavers, Edwards⁵ of Brookline, Mass., has taken the location of the medial upper border of the fossa ovalis to average 2.5 cm. lateral to the pubic tubercle and 1.5 cm. below it. In addition to this approximate anatomic location the course of the vein in the upper thigh is marked with an applicator dipped in alcoholic gentian violet or other suitable stain. In many cases the saphenous in this region is not visible and is buried deep in fatty tissue. In such a case the percussion method of McPheeters of Minneapolis is used to outline its course. This method, or the P P T test, standing for percussion pulse transmitted, is carried out by having the patient stand on the opposite leg to relax the muscles of the affected leg and then percussing the vein at one point with the fingers of one hand and receiving the transmitted impulse with a finger of the other hand, moving both about until the course of the vein is outlined.⁶

The line of the incision is infiltrated with a local anesthetic by means of a blunt pliable spinal needle after the initial wheal is raised. Before each injection is made aspiration is performed to make sure that one is not in a vein. The vertical incision is then made carefully and slowly, because in some cases the vein lies directly beneath the skin, although it usually is buried deep in the superficial fascia. This fascia may be found to be very fibrous, since it is a downward continuation of Scarpa's fascia of the abdomen, gradually ending in the region of the middle of the thigh. Directly over the saphenous opening or fossa ovalis it is called the cribriform fascia. Dissection of all the branches spoken of is performed, and the saphenous vein is exposed up to its junction with the femoral. All branches are clamped, sectioned and

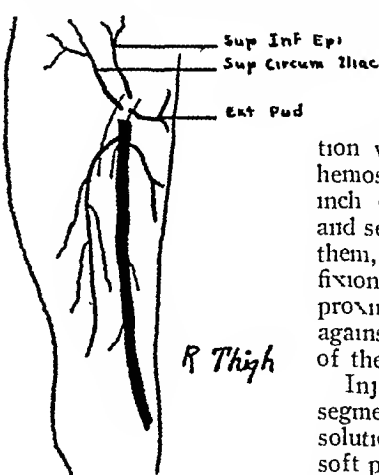

Fig 4—The superficial circumflex iliac, the external pudendal and the superficial inferior epigastric emptying directly into the femoral vein

ligated. The saphenous is then ligated with chromic catgut approximately 1 inch or closer to its junction with the femoral. A hemostat is then clamped 1 inch distal to the ligation and section is made between them, after which a transfixion suture is taken in the proximal stump to insure against a later "blow out" of the ligations.⁷

Injection of the distal segment with sclerosing solutions can be done with a soft pliable cannula. If one cannot be obtained, a stiffer cannula can easily be made from the shaft of a broken tonsil needle. The solution employed is 5 per cent sodium ricinoleate used in doses of from 4 to 10 cc., depending on the size of the vein.⁸ After the injection the cannula is removed, and ligation and transfixion are

done as before. After the wound has been flushed with sterile physiologic solution of sodium chloride, closure is done with dermal sutures or clips.

The dressing applied over this wound is quite important if the patient is to be ambulatory, as all these patients are. This dressing must not slip and it must be kept free from infection from gravitating sweat. Needless to say, this region is difficult to bandage. De Takats of Chicago uses a glue made from gum mastic 40 Gm., castor oil 20 drops and benzene 60 cc.⁹ Recently the elastic adhesive prepared by one of the nationally known pharmaceutical houses has proved of considerable worth. It comes in a tube and is easily applied and will easily hold any type of gauze dressing in place. Reinforcing dressings are taped over the glued dressing.

After the patient has taken a few steps around the operating room, any sacculi should be compressed with a pledget of cotton and taped in position. The walking is to distribute the solution and dilute it, while the sacculi compression is to aid in preventing a slough through its thin walls. This occurred in one of my cases at a point 12 inches from the site of injection, it can be best guarded against in that manner. Then a 3 or 4 inch Ace bandage is applied to the operated leg up to the knee. The patient is next asked to walk approximately eight or ten city blocks. The latter precaution is done to minimize the chances of pulmonary embolism and to help distribute more widely the sclerosing fluid.¹⁰

RESULTS

After a ligation-injection operation the patient experiences a burning sensation throughout the course of the vein. It becomes markedly reddened and tender but does not prevent his walking about. This burning leaves within twenty-four hours and the tenderness and redness subside in three or four days. The patient can usually tell to what point the sclerosing fluid gravitates in the leg, and this point marks its action on the vein. Wound sutures are removed in one week.

The dull pain and aches present before the operation in the affected leg are all gone within the first week. After a period of from one to two months has elapsed the patient is asked to return for a check up as to the extent of obliteration, and any patent veins or branches found then are given injections directly.¹¹ Varicosities of the small saphenous vein on the back of the calf of the leg are cared for at this time also.

Thus far there have been no reports of recurrence following this type of operation, either from dilatation of branches and recanalization of the old vein or from new venous channels through the inguinal scar.

Fatigue in the affected leg disappears quickly, likewise edema, eczema and cramps. Leg ulcers stop oozing and bleeding and take on a more healthy appearance. At times later injections are necessary to occlude any feeder veins around an ulcer. Legs with large ulcers are bandaged with an elastoplast bandage instead of the plain Ace bandage.

SUMMARY

1. Recurrence in cases presenting incompetent saphenofemoral valves when treated by injection alone or by ligation and injection alone is far too common.

⁹ de Takats, Geza and Quillin Lawrence. Ligation of the Saphenous Vein. Arch Surg 26 72 (Jan.) 1933. de Takats.
¹⁰ Colt, G. H., Ramsey, Isobel S. W. and Morrison, Margaret V. M. The Injection of Varicose Veins. Brit. M. J. (July 13) 1935.
¹¹ Swinton, N. W. Recent Trends in the Treatment of Varicose Veins and Varicose Ulcers. S. Clin. North America 16 1723 (Dec) 1936.

2. Ligation at the saphenofemoral junction, dissecting out and section of all five branches at that level and injection of the distal end of the saphenous vein, is the treatment of choice.

3. All cases in which the saphenofemoral valves are incompetent are indicated for the ligation injection treatment.

Until some newer idea or operation supplants the ligation-injection form of treatment, it must be admitted that it gives the greatest promise of permanent success with the least amount of danger, pain or mutilation in the more extensive varicose veins.

Clinical Notes, Suggestions and New Instruments

BURSITIS OF SARTORIUS BURSA AN UNDESCRIBED MALADY SIMULATING CHRONIC ARTHRITIS

ELI MOSCHCOWITZ, M.D., NEW YORK

The disease I am about to describe is fairly common. I have seen approximately twenty or twenty-five cases in the past ten years. For an unknown reason the malady occurs almost exclusively in women. The history is quite characteristic and pathognomonic. These patients complain of pain in both knees only on ascending or descending stairs. Walking on the level is not painful in the least. On examination, movement of the knee joint in both extension and flexion causes no pain. The joint itself is not tender. On the other hand, a tender area is found on the inner tibia at the exact site of the insertion of the conjoined tendon of the sartorius, semitendinosus and gracilis tendons. Occasionally a slight swelling is found in this area but, as a rule, only tenderness is present. X-ray examination of the joint reveals no evidence of arthritis. In a few instances I made lateral X-ray films of this area but nothing abnormal was found. In almost every instance the patient had large lower limbs, out of proportion to the size of the body. In some instances there was overweight. My explanation of the malady is that it is a bursitis. According to Quain, there are two bursae in this region: (1) the bursa anserina between the conjoined tendon of the gracilis and semitendinosus muscles and the head of the tibia, and (2) the bursa musculi sartorii proprii lying between the tendon of the sartorius muscle and the conjoined tendon of the gracilis and semitendinosus muscles. Occasionally there is a communication between these two bursae. In all probability the bursitis results from strain in the use of the sartorius and gracilis muscles, which act to lift the body in stepping upward and downward.

I have not been able to find the syndrome I have described in the textbooks on surgery or orthopedics, nor is there any mention of it in the Index Catalogue of the Surgeon General's Library or in recent medical literature. Reichel¹ remarks that inflammation of the bursa anserina may result after trauma, gonorrhea, syphilis or tuberculosis but does not mention clinical features. Rose and Carless² say that the bursa beneath the insertion of the semitendinosus and gracilis is sometimes inflamed and is liable to cause osteoplastic periostitis of the subjacent inner surface of the tibia. Hertzler³ mentions bursitis of the anserina bursa. He says that no definite movement can be identified as the one most likely to cause pain and that the area of tenderness is difficult to localize.

I have treated this malady in various ways and have found that the best results are obtained by treatment for reduction of weight. I have found no short road to success. Obviously the recognition of the disease is important from the point of view of prognosis.

THE USE OF THE PHOSPHATASE TEST IN DETECTING UNDERPASTEURIZED MILK IN SAN FRANCISCO

J C GEIGER M.D., AND CLINTON DAVIS Ph.G. SAN FRANCISCO

The legal standards for the process of pasteurization of milk supplies have been well defined and clarified. Likewise the process is generally accepted as a safety measure particularly in city milk supplies and often in the home.

The question as to whether or not a milk has been adequately pasteurized has long been a problem for organizations engaged in dairy control work. Local inspection at the plant depends on observation of the charts used to record the length of time and the temperature. The accuracy of these charts depends on the care and attention given by the pasteurizing management and employees. The laboratory, however, has looked for a simple objective test in an effort to determine when the finished product is satisfactory and safe. To accomplish this, considerable attention has been given to the enzymes amylase and phosphatase which are present in raw milk. Rothenfusser¹ worked out a test for pasteurized milk by the use of iodine and starch. Scharer² modified this test by eliminating the basic lead acetate and using acetic acid-chloroform reagent. These two tests were for detecting the presence or absence of the enzyme amylase. Bengen's³ test was based on the fact that by heating milk for at least five minutes at 63-65 C a small portion of milk albumin is denatured and later precipitated.

The laboratory of the San Francisco Department of Public Health has used the Rothenfusser test and Scharer's modification of this test for the past four years. Experience in the use of these tests indicates either that the amylase may vary in the different herds supplying milk to San Francisco or that the α -amylase and β -amylase withstand heating at 65 C for thirty minutes, thereby making the starch-iodine reaction unreliable. The report of Richardson and Hankinson⁴ seems to confirm the latter observation.

The phosphatase test of Kay and Graham,⁵ however, appeared to offer more reliable results. Therefore in February 1937 any further tests on the amylase were discontinued and the phosphatase test was substituted. The test briefly is as follows:

1 To 10 cc of the buffer substrate solution (one tablet containing disodium phenylphosphate and sodium barbitone is dissolved in 50 cc of water) contained in a 25 cc stoppered test tube, add 0.5 cc of the milk and mix thoroughly.

Results of Test Runs

Source	Time	Temperature F	Color	Interpretation
Receiving vat		57	Deep blue	Unheated
Vat before pasteurizing	11 00 a m	74	Deep blue	Unheated

Bottled	12 25		Faint blue	Pasteurized

2 Add two drops of chloroform, stopper the tube and incubate at from 37 to 38 C for one hour.

3 At the end of this time, add 4.5 cc of the diluted Folin and Ciocalteu reagent (1 volume of reagent and 2 volumes of water) mix, allow to stand for three minutes and filter.

4 To 10 cc of the filtrate add 2 cc of the sodium carbonate solution (14 per cent anhydrous sodium carbonate) mix thoroughly and place in boiling water for five minutes and again filter.

5 Compare the color of the filtrate in a 13 mm tube with the Lovibond standard 2.3 blue glass in the "Limitester."

If the color of the filtrate exceeds that of the standard glass it may be safely assumed that the milk has been improperly pasteurized, that is, the temperature has been too low or the time of heating too short.

During the period that the phosphatase test has been used, 155 samples of pasteurized milk and cream have been examined. Of this number twenty-five, or approximately 16 per cent, were classified as being inadequately pasteurized. The twenty-five specimens were from three plants, taken at irregular intervals. One particular milk plant was a persistent offender and as a result an inspector was detailed to observe and check the operation from the time that the milk arrived until the end of the pasteurizing period. The milk was then brought to the laboratory and tested. Subsequently this particular dairy plant produced an adequately pasteurized milk.

The operators of all dairy plants were notified that shortening of the pasteurization time can be demonstrated by the phosphatase test and would not be tolerated. As a result of this warning all the pasteurized milk and cream examined in the laboratory have passed this test satisfactorily.

In order to examine the practicability of the phosphatase test more fully specimens of milk were withdrawn from the pasteurizing vat of commercial plants at ten minute intervals and submitted to the laboratory for examination.

The results of the test runs are given in the accompanying table.

CONCLUSIONS

1 The experience of the San Francisco Department of Public Health with the phosphatase test as advocated by Kay and Graham would indicate that adequately pasteurized milk will invariably give a negative test.

2 This test, therefore, offers reliable laboratory evidence to confirm proper pasteurization of milk and cream of market supplies.

MENTAL DISTURBANCES FROM ATROPINE OR NOVATROPINE GIVEN TO SUBJECTS UNDER THE INFLUENCE OF INSULIN

J P QUIGLEY, Ph.D., CLEVELAND

A dangerous situation may develop if atropine or related compounds are administered after the use of insulin. I have observed in a significant proportion of cases that therapeutic doses, although relatively innocuous when employed alone, may produce marked mental symptoms when acting together.

Atropine is frequently employed therapeutically in doses of from 0.6 to 1.8 mg and rarely produces mental symptoms except in persons who are sensitive to atropine. Large doses (from 8 to 10 mg), however, may produce exaltation, excitement, talkativeness, amnesia, hallucinations, psychic confusion and sensory delusions.¹ In fifteen experiments in which my subjects received from 0.6 to 1.8 mg of atropine alone, or what approximately corresponds to it, from 2.5 to 3.5 mg of novatropine, mental disturbances never developed. I also performed twenty-four experiments in which 20 units of insulin was used as the sole medication. No symptoms were produced more marked than apprehension, sweating, hunger, trembling and weakness. Pronounced hypoglycemia can produce mental confusion, amnesia, slow and unintelligible speech, and the like.²

Six normal medical students were the subjects for twenty-three experiments in which the drugs were used in combination. After a fasting period of approximately eight hours, from 12 to 20 units of insulin was administered subcutaneously. About an hour and a half later a mild hypoglycemic reaction developed: anxiety, sweating, trembling, weakness and gastric hypermotility were present in moderate forms. At this time the subcutaneous administration of atropine (from 0.6 to 1.8 mg) or novatropine (from 2.5 to 3.5 mg) resulted within eight minutes in a complete disappearance of all the symptoms mentioned subjectively and objectively; the individuals felt normal and showed entirely

normal behavior. At this stage of the action the two preparations are antagonistic. The antagonistic effect also applies to gastric motility, as has been reported in detail elsewhere.³

On twelve occasions cerebral manifestations developed. The most pronounced response (obtained in six experiments) took the following pattern. The subjects remained quiet, frequently sleeping for approximately twenty-five minutes (or longer if undisturbed) following the administration of atropine or novatropine. At the end of this interval, when an attempt was made to converse, the speech was found to be disconnected and moderately hesitant. The subjects stated that difficulty was encountered in speaking words that they had clearly in mind. This statement minimized the situation, for the mental processes were actually dulled and distorted. Incorrect, though frequently logical, answers were given to questions. Imaginary but not necessarily impossible experiences were related with full belief in their validity. The thoughts wandered and were confused so that spontaneous speech was fragmentary and vacillating. The most outstanding symptom was a state of complete amnesia.

Giddiness, staggering or other disturbances in locomotion were not evident, except that walking as well as other movements was slow and deliberate. Commands were willingly obeyed and the subject's general behavior suggested automatism.

When food was proffered it was readily consumed. The mouth and throat were dry, thus deglutition was moderately difficult. A mild thirst was experienced. Within twenty to thirty minutes of ingesting approximately 200 Gm of food, chiefly carbohydrates, the symptoms had completely disappeared. Evidently the hypoglycemic state was essential for the development and maintenance of the cerebral effects. In the absence of further ingestion of food, the cerebral effects reappeared on a few occasions in mild form after approximately an hour.

Although the symptoms bore some resemblance to those from toxic doses of atropine or insulin, they differed from them in significant respects and constituted a distinct picture, thus substantiating the conclusion that they did not result from a toxic dose of either drug alone. In contradistinction to atropine poisoning, excitement and loquaciousness did not develop, while hallucinations or delusions were absent or not pronounced. The size of the pupil and the reactions to light remained normal, and no disturbance of vision was observed except in one person who received 20 units of insulin followed by 35 mg of novatropine and subsequently experienced moderate dilatation of the pupil and a decrease in accommodation, making it impossible to read ordinary print when held 1 foot from the eyes. The skin did not become flushed or hot and dry, nor were abnormal skin sensations experienced. The usual symptoms of hypoglycemia (weakness, sweating, hunger, trembling, apprehension and the like) were not experienced during this interval.

Following the administration of atropine, the symptoms in four experiments were similar to those previously described but more mild, and in two experiments the only unusual symptoms were disturbances of speech and amnesia. In the remaining eleven experiments, mental disturbances did not develop and the subjects experienced only a complete relief from the hypoglycemic symptoms. Two subjects were more inclined to display the pronounced effects but no subject persistently failed to show the phenomenon.

CONCLUSIONS

The manifestations of insulin hypoglycemia occurring in man (anxiety, trembling, sweating, weakness and gastric hypermotility) were effectively counteracted by the administration of moderate doses of atropine (from 0.6 to 1.8 mg) or novatropine (from 2.5 to 3.5 mg).

Subsequently in 50 per cent of the experiments a synergistic action of insulin with atropine or novatropine developed, consisting of pronounced mental disturbances (chiefly amnesia and speech disturbances) of varying intensity.

The observations justify a warning against the administration of atropine preparations to a subject in the hypoglycemic state probably without regard to the mechanism by which the hypoglycemia is produced.

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
HOWARD A. CARTER, Secretary

LEPEL SWP PORTABLE SHORT WAVE DIATHERMY MACHINE ACCEPTABLE

Manufacturer: Lepel High Frequency Laboratories, Inc., New York

The Lepel SWP Portable Short Wave Diathermy Machine is designed for medical and surgical use. It operates by means of a spark gap instead of tubes. The circuit differs only in minor details from one in the unit previously accepted by the Council (*THE JOURNAL*, Nov. 16, 1935, p. 1606). Various types of electrodes may be used with this unit: air-spaced condensers, cuff electrodes, the inductance cable and those designed for surgery.

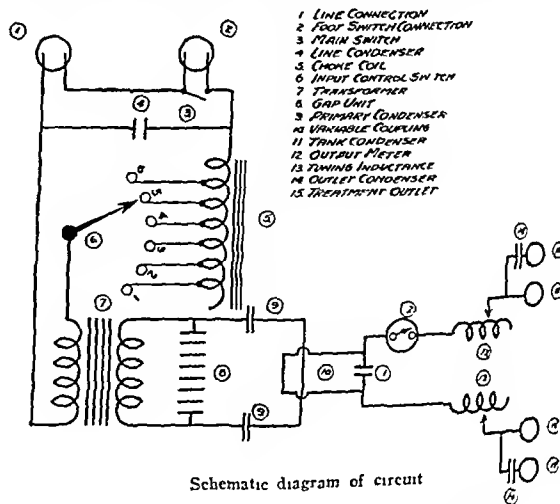

The wavelength for this machine is between 12 and 13 meters, as measured in the tank circuit without the treatment electrodes attached. When the treatment electrodes are attached, two wavelengths result in the patient circuit, one shorter and one longer than the tank circuit wavelength. The shorter is around 10.5 meters and the longer between 14 and 15 meters.

Lepel SWP Portable Short Wave Diathermy Machine.

The input required to operate the machine at full load is 82 amperes at 117 volts. Since no reliable method has been proposed to measure the output energy available to the patient, the value is not given. When operated at full load for two hours the transformer temperature rise met the requirements acceptable to the Council.

The firm presented evidence to substantiate its claims concerning the heating ability of the unit with plate and coil technique and also observations on its performance in pelvic heating.

Schematic diagram of circuit

Data were not required on the cuff technique because the circuit of the new unit differs only slightly from the one reported previously giving the cuff measurements. Reliable investigators performed tests on the machine for the firm. Tests employing the plate and coil technique were run. There were two observations on each of four subjects: air-spaced electrodes being used in six cases and the inductance coil in two cases. The tests are described as follows.

Plate Technique.—The plates were rectangular 9 by 23 cm. left in place so as to maintain approximately constant distance from the skin. The distance averaged 2 cm. Of this space 1.5 cm. was occupied by the

foam rubber composition into which the plates were molded. A layer of air with an average thickness of 0.5 cm was maintained between the rubber and the skin. The electrodes were supported on the arms provided with the machine care being taken that the air space was maintained at all times. Both electrodes were placed on the anterior aspect of the thigh—one just above the knee and the other on the upper thigh. The average distance between the centers of the plates was 17.2 cm. The average distance between the nearest plate edges was 5.7 cm. The average thigh circumference of the subject was 43 cm.

In all these tests the machine was operated on contact button 5 tuned to resonance for ten minutes then raised to contact button 6 full output for the remainder of the twenty minute test period. The room temperature varied from 68 to 76 F. The room humidity ranged from 48 to 59 per cent.

The average temperatures of six observations, with air-spaced technic, and the average in two observations, coil technic, are given.

Average Temperatures in Six Observations Air Spaced Technic

Deep Muscle		Subcutaneous		Skin		Mouth		Rectal	
Initial	Final	Initial	Final	Initial	Final	Initial	Final	Initial	Final
97.1	106.2	93.9	104.8	88.9	95	95.7	98.9	98.9	99.1

Average Temperatures in Two Observations Coil Technic

97.4	105.0	93.9	103.3	88.1	93.1	98.8	99.1	99.2	99.2
------	-------	------	-------	------	------	------	------	------	------

Coil Technic—In both tests carried out with this technic a 9 foot coil was used, four convolutions being wrapped about the thigh of the subject. In one test the coil was separated into two portions, i. e. two turns spaced an inch apart above the knee the other two turns also spaced an inch apart placed on the upper part of the thigh leaving a clear space of 3 inches on the anterior aspect between the middle turns. In the second test the coil was wound uniformly and consisted of four turns spaced an inch apart. Measurements were made at the center of the coil in each case.

The room temperature varied from 70 to 74 F. the humidity from 50 to 61 per cent. The machine was set as in the tests on plate technic.

The firm also furnished evidence with regard to pelvic heating. The technic for pelvic heating consisted in using a metal vaginal electrode with hollow stem holding thermometer and a large condenser pad over the abdomen. The treatment was administered at comfortable tolerance of the patient. The averages for five treatments are given here. The initial reading was taken at once without allowing the temperature of the electrode to reach the surrounding temperature.

Average Pelvic Temperatures in Six Observations

Initial 95.4	Final 106.9
--------------	-------------

Average Temperature in Three Observations, Plate Technic

Deep Muscle		Oral	
Initial	Final	Initial	Final
97.1	103.7	98.1	98.5

The Lepel SWP unit was placed in a clinic acceptable to the Council for investigation. A qualified investigator was authorized by the Council to run tests for determining the heating produced in the human thigh when employing both plate and coil techniques. The investigator used the customary thermocouple method of obtaining temperatures in the thigh. His final tem-

Average Temperatures in Three Observations, Coil Technic

Deep Muscle		Oral	
Initial	Final	Initial	Final
98.4	102.8	98.4	98.7

perature readings for deep muscle were somewhat less than those submitted by the firm. Two male subjects were used. Three observations were made with each technic. For one, two plates, 9 by 23 cm, were placed equidistant from the cannula on the anterior aspect of the thigh and in the same plane. Contact No. 6 was employed. Skin tolerance of the patient was the gauge of dosage.

For the coil technic, four turns of the cable were placed around the thigh with coils $2\frac{1}{2}$ inches apart, center to center. Two layers of bath toweling were used for spacing.

Since the temperature readings obtained during the investigation carried out under the direction of the Council met its requirements the Council voted to include the Lepel SWP Portable Short Wave Diathermy Machine in its list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES OF WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH Secretary

SODIUM MORRHUATE (See New and Nonofficial Remedies, 1937, p. 431)

The following dosage forms have been accepted.

Ampul Vials Solution Sodium Morrhuate 5% with Benzyl Alcohol 2% 5 cc size. Each cubic centimeter contains 0.05 Gm sodium morrhuate and 0.02 Gm benzyl alcohol in aqueous solution.

Ampul Vials Solution Sodium Morrhuate 5% with Benzyl Alcohol 2% 25 cc size. Each cubic centimeter contains 0.05 Gm sodium morrhuate and 0.02 Gm benzyl alcohol in aqueous solution.

Ampul Vials Solution Sodium Morrhuate 10% with Benzyl Alcohol 2% 25 cc size. Each cubic centimeter contains 0.1 Gm sodium morrhuate and 0.02 Gm benzyl alcohol in aqueous solution.

Prepared by the National Drug Co. Philadelphia. No U. S. patent or trademark.

PENTOBARBITAL-SODIUM-LILLY (See New and Nonofficial Remedies, 1937, p. 112)

The following dosage forms have been accepted.

Pulules Pentobarbital Sodium Lilly, $\frac{3}{4}$ grain. Pentobarbital sodium N. N. R. 0.05 Gm ($\frac{3}{4}$ grain) and starch 0.075 Gm.

Suppositories Pentobarbital Sodium Lilly, 2 grains. Each suppository contains pentobarbital sodium N. N. R. 0.13 Gm (2 grains) in a cocoa butter base.

CARBON DIOXIDE—Carbonic Acid Gas—Contains not less than 99 per cent by volume of CO₂.

For standards see U. S. Pharmacopeia under Carbonic Dioxide.

Actions and Uses—Carbon dioxide is the natural stimulant to respiration. It is frequently added to oxygen in varying proportions for supplying artificial respiration, and as a stimulant to the respiratory center. The proportions must be regulated carefully. A great excess of carbon dioxide causes death by asphyxia.

"Pureco" Carbonic Acid Gas—A brand of carbon dioxide—U. S. P.

Manufactured by Pure Carbonic Inc. New York, N. Y. No U. S. patent.

LAROCAINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1937, p. 60)

The following additional dosage form has been accepted.

Tablets Larocaine Hydrochloride 0.25 Gm. Each tablet contains larocaine hydrochloride 0.25 Gm and boric acid 0.025 Gm.

PROCAINE-ABBOTT (See New and Nonofficial Remedies, 1937, p. 69)

The following additional dosage forms have been accepted.

Amponles Solution Ephedrine Hydrochloride 2.5 per cent and Procaine Hydrochloride 1 per cent 2 cc.

Amponles Solution Ephedrine Hydrochloride 5 per cent and Procaine Hydrochloride 1 per cent 1 cc.

CHAPPEL LIVER EXTRACT (SUBCUTANEOUS) (See New and Nonofficial Remedies, 1937, p. 317)

The following dosage form has been accepted.

Vials Chappel Liver Extract (Subcutaneous) 10 cc.

SULFANILAMIDE (See THE JOURNAL, July 31, 1937, p. 358)

Sulfanilamide-Lilly—A brand of sulfanilamide N. N. R. Manufactured by Eli Lilly and Co. Indianapolis. No U. S. patent or trademark.

Sulfanilamide Tablets 5 grains.

PSYCHOTHERAPY IN GYNECOLOGY AND OBSTETRICS

The role of psychogenic factors in functional disorders is now widely recognized Such symptoms as leukorrhea, dyspareunia and frigidity (often associated), vaginismus, dysmenorrhea, hyperemesis gravidarum, pseudocyesis, and even amenorrhea and menorrhagia, often have their origin in psychopathologic states Disturbances in puberty and in the menopause bear a distinct psychopathic stigma Far too frequently women undergo radical operation for relief of symptoms without obtaining improvement Sixty per cent of a group of clinic patients studied by Johnson¹ were not improved after various pelvic operations Of these women 76 per cent subsequently had pain in the lower part of the abdomen, 34 per cent had a sense of weight in the pelvis and backache, 24 per cent had menstrual disturbances, and 52 per cent had chronic endocervicitis Johnson considers them to be "inadequate individuals," 50 per cent having family histories of nervous disorders or insanity, 32 per cent a history of tuberculosis and 14 per cent a history of thyroid dysfunction, 84 per cent had been pregnant, with an average of three pregnancies, and less than 24 per cent had had more than a grade school education Economic and social disturbances, malnourishment, the fear of repeated pregnancies, and marital discord were important factors in causing the symptoms in these fifty women

The difficulty of proving such symptoms to be of psychic origin by experimental means was brought out by Horney² Dysmenorrhea, for example, may not be the result of a single emotional strain or conflict but of a series of them, perhaps spaced over several years The logical approach to a successful solution of the problem is a historical one A careful, sympathetic elicitation of the woman's emotional and psychologic biography may often reveal the connection between such conflicts and her present complaints

Mayer³ believes that pelvic symptoms are exaggerated more readily than others because many emotional conflicts of women resulting from personal and social restrictions, besides the normal processes of menstruation, defloration and childbirth (all associated with pain and bleeding), center attention on the genital zone and predispose to undue anxiety in connection with local symptoms The functional cycles are under endocrine control, which is influenced by changes in the sympathetic nervous apparatus, increasing the vulnerability Acute or chronic psychologic influences, such as a fear or frustrated hopes, are associated not only with symptoms but with organic change Amenorrhea may be a symptom of mental disorders of wide range Irregular or excessive bleeding may have a psychopathic basis, although here diagnostic curettage should precede the drawing of such a conclusion Prolonged mental treatment may be needed in dysmenorrhea in which psychogenic factors are responsible or at least contributory Certainly expert psychotherapy is indicated before radical operative intervention is attempted Dyspareunia is usually psychogenic in origin, after the patient's confidence has been secured psychotherapy in addition to local treatment often accomplishes brilliant results Pruritus vulvae and leukorrhea respond to psychotherapy when there are mental contributory factors Often the chief symptom is found to be one of many symptoms appearing in sequence or in groups To the patient they are "useful" symptoms, defending her against whatever is threatening her, even though she is not cognizant of this Other gynecologic problems have psychologic factors which require insight and careful handling, such as in the field of contraception, the treatment of sterility, the prevention of cancerophobia and the treatment of endocrinologic and congenital gynecologic abnormalities

When the determined organic changes fail to explain a gynecologic complaint, the physician must consider the possibility of a psychogenic cause which may be accessible to himself or to one more expert in psychologic methods Some objections have been raised as to the propriety of the administration of psychotherapy by one who is treating organic ills as well, but in the great majority of cases no ground for such objection exists Most of these patients do not require formal psychoanalysis but perhaps only simple suggestive treatment, which is best received from their own physician What is obviously required is the gaining of the patient's complete confidence, an intelligent psychanalysis, the removal of anxiety where possible, assistance in the acceptance of reality, instead of a retreat from it, perhaps a change of environment, a building up of the general resistance local treatment with its suggestive potency, and the judicious use of sedative with recourse to a psychoanalyst familiar with the problems when necessary

DEATHS FOLLOWING ELIXIR OF SULFANILAMIDE-MASSENGILL

Nine out of ten patients who had been given a proprietary elixir of sulfanilamide died recently in Tulsa, Okla., from anuria which apparently resulted directly from poisoning by this elixir.¹ As we go to press, the record is swelled by the report of four additional deaths with another likely fatality in East St. Louis. The product was prepared and sold by the S. E. Massengill Company of Bristol, Tenn. From tests by the chemical laboratory of the American Medical Association, this elixir appears to be a solution of approximately 40 grains of sulfanilamide to a fluidounce of a menstruum containing about 72 per cent of diethylene glycol (by volume) with flavoring. Apparently it is not known whether the toxicity of sulfanilamide is enhanced by the presence of diethylene glycol—or vice versa. The solvent, diethylene glycol, is itself not an indifferent substance. While its use is not permitted in food products because of the absence of any scientific evidence establishing beyond doubt its harmlessness when taken internally, it has long been utilized as a solvent in various industrial processes. The dosage of the elixir administered unquestionably contained a large amount of this substance. It would appear to be clear that the diethylene glycol or the diethylene glycol-sulfanilamide combination rather than the sulfanilamide was responsible, one of the patients had received tablets over a period of two weeks without any bad effects and then showed the typical train of symptoms after taking the elixir. From twenty-four to forty-eight hours after administration of the substance, nausea, vomiting, malaise and sometimes diarrhea developed, then complete anuria appeared within two to five days. The nonprotein nitrogen, urea nitrogen and creatinine rose rapidly. In the postmortem examination there was usually an accumulation of fluid in the serous cavities, with degeneration of the tubules of the kidney and a peripheral necrosis of the liver.

The laboratory of the American Medical Association is conducting careful chemical and pharmacologic experiments to indicate the toxic factors of the elixir concerned. Possibly other factors may be involved such as the decomposition of the sulfanilamide in the presence of the aqueous diethylene glycol solution.² Possibly there may have been some error in the process of manufacture. Indeed the possibilities are unlimited, since we are here concerned with a preparation not standardized by any reliable agency, semisecret in composition and apparently hastily rushed into the market to meet an overenthusiastic reception of a new remedy.

This tragic experience should be a final warning to physicians relative to the prescribing and administration

of semisecret, unstandardized preparations. It would indeed be a pity if this tragedy were to be repeated again and again as more and more new remedies are put forth. THE JOURNAL and the Council on Pharmacy and Chemistry of the American Medical Association have been alert in their attempts to inform the medical profession as to the status of sulfanilamide. The Council on Pharmacy and Chemistry has not accepted any stock solution of this substance. It has accepted a sufficient number of preparations developed by manufacturers to supply the needs of the medical profession for this substance in the present state of our knowledge. Acceptance by the Council indicates that the products have been examined and that there is sufficient clinical evidence relating to their use to indicate at least their safety when prescribed in the designated manner.

A physician is not compelled to follow the United States Pharmacopeia, the National Formulary or the Council on Pharmacy and Chemistry in the prescribing of drugs. He may, if he wishes, prescribe anything that he thinks may be of benefit for his patient. Indeed, the Council on Pharmacy and Chemistry encourages scientific experimentation with new remedies, provided these experiments are carried out with suitable controls and with adequate facilities for therapeutic investigation. In the usual conditions of practice, however, it is far safer—as this tragedy again emphasizes—to limit prescriptions of nonofficial products to those accepted by the Council on Pharmacy and Chemistry and to use them as described in New and Nonofficial Remedies.

Current Comment

LIPOID PNEUMONIA AND OIL IN THE LUNGS

Fatal cases of pneumonia due to the aspiration of oily preparations into the lungs have been reported in the American medical literature as lipoid pneumonia since 1925. The condition is observed usually in children under 2 years, generally the result of too frequent instillations of oily nose drops. As recently as 1935, cases were reported by Karelitz and Denzer,¹ Langdon,² Garrison³ and Cannon,⁴ and in 1936 by Klinck⁵ and by Baumgartner and Angevine.⁶ The pathologic anatomy has been variously described. In the case cited by Cannon, necropsy showed the following essential features: "pneumonia due to aspiration of lipoid, with extensive formation of abscesses in the right upper and lower lobes, focal fibrinous and fibrinopurulent pleuritis on the right side, acute generalized fibrinopurulent peritonitis and suppurative otitis media on the left side." Klinck stated that the fats and oils which cause this disease reach the alveoli of the lungs, where they col-

1 In the preparation of this editorial THE JOURNAL has been aided by information received through Drs. James Stevenson, president of the Tulsa County Medical Society; Homer A. Ruprecht of the Springer Clinic, Tulsa; Darwin B. Childs of the Childs Clinic, Tulsa; and I. A. Nelson of the Springer Clinic, Tulsa. Officials of the Massengill Company have sent a confidential statement of the composition of the product.

2 The Chemical Laboratory found no evidence of decomposition of sulfanilamide in the specimen of elixir examined.

lect and give rise to chronic inflammatory processes resulting in fibrosis. Lipoid pneumonia of the adult type, Ikeda⁷ says, is a distinct clinicopathologic entity. Liquid petrolatum is the chief etiologic agent. The pneumonia develops slowly over a period of years and is invariably accompanied by bronchopulmonary symptoms. The typical pulmonary lesion represents a chronic nonspecific nonsuppurative granulomatous foreign body leading to ultimate tumefaction and fibrosis. These patients, Bolduan⁸ says in a recent bulletin prepared for the information of the medical and nursing personnel of the department of health of New York City, show the clinical signs and symptoms of a low grade pneumonia, and examination with x-rays usually shows a shadow along the sternal border of the pulmonary fields. At necropsy the lungs show evidence of the reaction of the tissues to a foreign body and the results of a secondary invasion by bacteria. Large amounts of oil are often present in the lung. Probably there are many cases of this disease other than the fatal ones that have been reported. Oily nasal drops are not the only agents that may cause this form of pneumonia in infants; cod liver oil and even cream have been involved in some of the cases. Although the majority of the reports have concerned infants under 2 years, frequently debilitated elderly people and adults weakened through illness also may be susceptible to pneumonia from this type of foreign body. The continued appearance of reports of fatal cases indicates the necessity for greater care in the use of oily materials in the respiratory tract.

NEW INVESTIGATIONS OF PROTEIN FRACTIONS

Although primarily of chemical interest, the fractionation of proteins involves a potentially significant aspect of the understanding of human physiology, especially that of the kidneys and blood. Thus fundamental work on the nature of proteins may rapidly become of medical interest. The brilliant investigations of Sorensen¹ have clearly indicated that, even after elaborate purification, proteins in solution are not homogeneous but are more accurately viewed as members of a reversibly dissociable system. Thus the isolation of a crystalline serum albumin may merely signify that certain components in the serum can combine into a product which is insoluble under those particular circumstances. Definite evidence of the lack of homogeneity of crystalline serum albumin has been recently advanced by Hewitt.² He succeeded in separating horse serum albumin into two utterly different fractions. One is a crystalline albumin which is free from carbohydrate, the other is a freely soluble fraction which cannot be readily coagulated by heat and which does contain considerable quantities of carbohydrate. Hewitt's investigations appear to corroborate Sorensen's conclusions.

They may indicate, however, that what Hewitt has done has been to alter the conditions for the isolation of the protein fractions which merely brings about a separation of two components of the dissociable systems usually called serum albumin. In complex protein solutions like blood serum, milk or egg white, several different component systems are present,³ and between these exists an equilibrium which depends on conditions in the solution. This equilibrium may be reversibly altered by changes in the composition of the solvent. The chief significance of these investigations and their interpretation is that the euglobulin, pseudoglobulin and serum albumin would seem to be fractions of a complex protein system rather than actually differing substances. If this is true and if their relative proportions can be altered by changing the salt concentration of the medium in which they are dissolved, the possibilities of improved therapeutics in certain diseases do not seem to be too far distant.

ACTION OF ANTISEPTICS IN MICE

It has long been recognized⁴ that the phenol coefficient as determined by routine in vitro technics is not a reliable index to the therapeutic usefulness of surgical antiseptics. A promising method of in vivo titration, however, has been recently suggested by Hunt.⁵ By this method 0.1 cc. of a 50 per cent dilution of a twenty-four hour broth culture of an "invasive strain" of *Staphylococcus aureus* is injected intracutaneously into a mouse. The hypodermic needle is dipped in India ink before injection in order to leave a permanent tattoo mark at the site of the injection. In untreated mice such an injection usually causes a local inflammatory reaction from 3 to 10 mm. in diameter, with subsequent suppuration, necrosis, scab formation, desquamation and spontaneous healing. The antiseptic solutions to be titrated are injected as aqueous solutions twenty times the minimum concentration necessary to kill staphylococci within ten minutes in the test tube. The dose is usually 0.1 cc. of the antiseptic injected through the permanent tattoo mark on the skin. "Disinfectant 1" (chlor-iso-octyl-resorcinol) has a test tube phenol coefficient of 1,800 when dissolved in distilled water, reduced to 500 in the presence of 1 per cent serum. In Hunt's hands a 1:5,000 dilution of this octyl resorcinol was able to prevent the formation of the skin lesion in mice if administered at the same time at which the area was infected with staphylococci. Given one hour after microbial injection, however, even a 1:1,000 dilution of this disinfectant was able to prevent the formation of the skin lesion in only one out of four mice. Administered three hours after infection of the skin area it had no demonstrable therapeutic effects. Merthiolate and metapen in 1:1,000 dilutions were without therapeutic effects even when the antiseptic solution and staphylococci were mixed prior to injection. Mercurochrome, oxyquinolin and chloramine T were equally ineffective.

Association News

RADIO BROADCASTS

The American Medical Association and the National Broadcasting Company present the fifth series of network health programs beginning Oct 13, 1937, and running weekly through June 15, 1938. The programs will be presented over the Red network each Wednesday at 2 p m eastern standard time, 1 p m central standard time, 12 o'clock noon mountain standard time and 11 a m Pacific standard time.

The dates and topics of the broadcasts for the coming month are as follows:

Personal Health

October 27—Seeing and Hearing Well: hearing and vision, how to conserve these, how to recognize deviations, how to prevent loss.

November 3—Striving for Better Bodies: so-called physical defects, their recognition, what can be done about them.

Hygiene

November 10—Playing for Fun: health values and hazards in sports and recreation including football.

November 17—Fresh Air, Fresh Clothes and Fresh Skin: ventilation, clothing, bathing.

November 24—Rest, Relaxation, Refreshment: all work and no play, or all play and no rest—bad for health.

The stations on the Red network are privileged to broadcast the program but, since it is a noncommercial program, they are not obligated to do so. Interest on the part of medical societies, women's auxiliaries and others may have weight with program directors of local stations. A personal visit to the program director might be advisable if the program is not being taken by a local station. This is an opportunity for the appropriate committees of county medical societies to indicate their interest in having this program broadcast in their community and to enlist the interest of other groups.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Prohibit Sale of Clams—Supplementing the regular mussel quarantine order of May 26, a quarantine of all clams from the ocean shore of California, extending from the southern boundary of Los Angeles County north to the California-Oregon boundary, with the exception of San Francisco Bay has been established, according to the state health department September 13. This order prohibits the taking, sale or offering for sale of clams gathered in the district specified.

COLORADO

Society News—The Medical Society of the City and County of Denver was addressed, October 5, by Drs Harry Gauss on 'Gastro-Intestinal Symptoms in Disease of the Brain', Luman E Daniels, 'Prevention of Late Neurosyphilis,' and Alfred R Masten, 'Tuberculosis Control.' At a recent meeting of the society, Drs Clarence B Ingraham discussed 'Pelvic Tumors', Gerrit Heusinkveld 'Malpositions of the Uterus,' and Eugene S Auer, 'Primary Dysmenorrhea.'

Officers of Basic Science Board—At the first meeting of the board of examiners in the basic sciences August 26, Charles F Poe Ph.D, University of Colorado, Boulder, was chosen president, Isaac E Newsom, D.V.S., Colorado Agricultural College Fort Collins, vice president, and Esther B Starks D.O., Denver, secretary treasurer. Other members of the board are Dr Edgar D Downing, Denver and R C Oppenlander, D.C., Sheridan. The bill creating the basic science board was enacted by the thirty-first general assembly and became effective July 1.

DISTRICT OF COLUMBIA

Personal—Dr William A Applegate has retired as chief surgeon of the Southern Railroad, after holding the position thirty-two years. Dr Glenn I Jones, Bethesda, Md, will succeed him.

The Davidson Lecture—Dr Harry A Davis, associate in pathology, University of Tennessee College of Medicine Memphis delivered the Davidson Lecture of the Medical Society of the District of Columbia October 13. Dr Davis was selected on the merit of his essay, submitted in competition, entitled 'Factors in the Production and Treatment of Shock: An Experimental Study.' The lecture was established in 1929 in honor of Dr Edward Young Davidson, who was largely responsible in bringing to completion the society's project of building its own home. It is given in odd numbered years on the second Wednesday in October. In 1936 the executive committee of the medical society decided to place the selection of the lecturer on a competitive basis. Dr Davis graduated from McGill University Faculty of Medicine, Montreal, in 1931.

FLORIDA

District Meeting—The first annual meeting of the North Central Medical District of the Florida Medical Association will be held at the Harrington Hall Hotel in Ocala, October 27. Dr Ralph E Russell, Ocala, president, Marion County Medical Society, will deliver the address of welcome, and officers of the state medical association will be among the speakers. Presenting the scientific program will be Drs Robert D Ferguson, Ocala, on 'Acute Conditions Within the Abdomen,' Edward Jelks, Jacksonville, 'Some Experiences in the Diagnosis of Gastro-Intestinal Cancer,' and James M Dell Jr, Gainesville, 'Complications Following Cauterization of the Cervix.'

ILLINOIS

Society News—Dr Frederick H Falls, Chicago among other speakers, discussed 'Eclampsic Toxemia' before the Adams County Medical Society, October 11, in Quincy. Drs John T Gernon, Chicago, and Paul H Harmon, Springfield, addressed the Kankakee County Medical Society, Kankakee October 14, on 'Neurogenic Dysfunction of the Bladder' and 'Poliomyelitis' respectively.

Chicago

Public Lecture on Medical Charlatans—Dr Morris Fishbein Editor of THE JOURNAL will deliver a public lecture at Goodman Theater, October 27 under the auspices of the Chicago Medical Society, on 'Modern Medical Charlatans.'

Lectures on Cancer—The Chicago Woman's Club, through its cancer research committee, began a series of public lectures on cancer, October 21, with a talk by Dr William A O'Brien, associate professor of pathology and preventive medicine and public health, University of Minnesota Medical School, Minneapolis. His subject was 'General Aspects of Cancer.' Other lecturers in the series are:

Dr Clark W Finnerud assistant clinical professor of dermatology, Rush Medical College University of Chicago October 28. Skin Cancer.

Dr Gatewood clinical professor of surgery Rush Medical College November 4. Cancer of the Digestive Tract with Special Reference to the Stomach and Rectum.

Dr Frank L Rector Evanston Ill field representative American Society for the Control of Cancer What Comprises Adequate Facilities for the Care of Cancer Patients.

Society News—At the annual joint meeting of the Institute of Medicine of Chicago and the Chicago Society of Internal Medicine, October 25, at the Palmer House, Sewall Wright D.Sc, Ernest D Burton distinguished professor of zoology, University of Chicago, will speak on 'The Hereditary Factor in Abnormal Development.'—Dr Edward L Jenkinson, among others addressed the Chicago Roentgen Society, October 14, on 'Cholecystography Before and After Medical Management.'

—At a meeting of the Chicago Pathological Society, October 11, the speakers included Drs Arthur Weil and Erich Liebert, Chicago, and Gert Heilbrunn, Elgin, on 'The Histopathology of the Brain in Experimental Hyperinsulinism.'—The Chicago Society of Allergy was addressed October 18 by Drs Tell Nelson on 'A Sheep Antibody to Pollen Which Blocks the Prausnitz-Kustner Reaction' and Paul Tachau on 'Eczema and Similar Dermatoses in Infancy and Childhood.'—Dr Charles F McKhann assistant professor of pediatrics and communicable diseases Harvard University Medical School Boston, addressed the Chicago Pediatric Society, October 19, among other speakers, on 'Cross Infections in an Infant and Children's Hospital.'

INDIANA

Society News—Dr John De J Pemberton, Rochester, Minn., addressed the Tippecanoe County Medical Society in Lafayette, September 14, on "Cancer of the Rectum and Rectosigmoid"—Dr James O Ritchey, Indianapolis, discussed undulant fever before the Jasper-Newton County Medical Society in Rensselaer, September 30—At a meeting of the Wabash County Medical Society in North Manchester, September 15, Dr John H Warvel, Indianapolis, discussed "Diabetes Mellitus in Children and Protamine Zinc Insulin"—Dr Louis H Segar, Indianapolis, addressed the Gibson County Medical Society in Princeton, September 13, on "Preventive Medicine in Children"—Dr Maxwell M Wintrobe, Baltimore, addressed the Indianapolis Medical Society, October 19, on "Diagnosis and Treatment of Anemias"—Dr Max A Bahr, Indianapolis, addressed a joint session of the society and the Indianapolis Bar Association, October 12, on "The Psychological Aspect of Crime"

IOWA

Personal—Dr Benjamin E Jones, Davenport, has retired as supreme medical director of the Modern Woodmen of America, after thirty-four years in the position

Society News—At a meeting of the Linn County Medical Society in Cedar Rapids, September 14, Drs Edward William A Ochser, New Orleans, discussed "Treatment of Peptic Ulcer Based on Physiologic Principles," and Edward H Ochser, Chicago, "Treatment of Septic Infections"—Dr Joseph Norman Bickert, Cedar Rapids, also spoke—A symposium on venereal diseases was presented before the Des Moines Academy of Medicine and Polk County Medical Society, September 28, by Drs Thomas P Bond, Julius S Weingart and Walter L Bierring

LOUISIANA

Society News—The Tri-Parish Medical Society was addressed in Tallulah, August 3, by Drs Ralph J Talbot, Monroe, on "Respiratory Difficulties of the New-Born", Isadore Dyer, New Orleans, "Practical Points in Prenatal Care and Management of Prenatal Complications" and "Venereal Disease Control"—At a meeting of the Bi-Parish Medical Society in Jackson recently Dr Richard W Young, Baton Rouge, read a paper on "Artificial Pneumothorax."

Tuberculosis Institute—A tuberculosis institute will be held at the Hutchinson Memorial Building Tulane University, New Orleans, November 22-23, under the auspices of the Tuberculosis Committee of New Orleans, the Orleans Parish Medical Society and the Louisiana State Tuberculosis Association—Drs Fred H C Heise, medical director of Trudeau Sanatorium, Trudeau, N Y, and John B Hawes II, Boston, director of the Rutland (Mass.) Cottage Sanatoria, will conduct the institute—Clinical demonstrations will be held in the afternoons and the diagnosis and treatment of tuberculosis will be discussed in the evenings

MAINE

Society News—At a recent meeting of the council of the Maine Medical Association, a special committee for furthering graduate education was appointed—The members are Drs Frederick T Hill, Waterville, chairman, Julius Gottlieb, Lewiston, and Norman H Nickerson, Greenville—Dr Richard B Cattell, Boston, among others, addressed a joint meeting of the Penobscot, Somerset, Kennebec and Piscataquis county medical associations at Kineo recently—his subject was "Diagnosis and Management of Surgical Lesions of the Colon and Rectum"—Dr Herbert R Kobes, Augusta addressed the Aroostook County Medical Association in Houlton recently on "Statewide Program for the Maine Crippled Child"

MASSACHUSETTS

Changes in State Health Department—Dr Roy F Feenster, Boston, has been appointed director of the state division of communicable diseases, succeeding Dr Gaylord W Anderson, who resigned to become professor of public health at the University of Minnesota Medical School—Dr Anderson's post as deputy health commissioner will be taken by Dr Alton S Pope, Boston, who will continue in his present capacity as director of the division of tuberculosis—Dr Feenster graduated at the Johns Hopkins University School of Medicine, Baltimore, in 1924

Society News—Dr Ralph M Towell Hartford Conn., addressed the Franklin District Medical Society in Greenfield, September 14 on "Anesthesia in Present Day Practice"—Dr John B Hawes II, Boston addressed the society recently

on "Dust and Its Effect on the Lungs" and the Berkshire Medical Society, Pittsfield, on "Relation of Industrial Dusts to Disease"—At a meeting of the Pentucket Association of Physicians, September 16, Dr Joel E Goldthwait, Boston spoke on "The Problem of the Arthritic"—The Four County Medical Society was addressed at Northampton, September 14 by Drs Channing Frothingham, Boston, on "How Shall We Meet Present Trends in Medicine?", Paul M Ashton, Springfield, "Practical Use of Endocrines in Gynecology," and Stanley C Cox, Holyoke, "Traumatic Surgery"

MICHIGAN

Society News—At an all day joint meeting of the Wayne County Medical Society and the Michigan Tuberculosis Association in Detroit, October 11, the speakers were, among others Dr John Hargreaves Harley Williams, medical commissioner of the National Association for the Prevention of Tuberculosis, London, England, "Fifty Years of Tuberculosis Control in England," and Philip P Jacobs, Ph D, New York, "Tuberculosis Control or Eradication—What's Ahead?"—Charles Sheard, Ph D, Rochester, Minn., addressed the Detroit Physiological Society, October 7, "The Control of Loss of Heat from the Body"

Conferences on Tuberculosis—A series of graduate conferences on tuberculosis will begin at the Herman Kiefer Hospital, Detroit October 27, when Dr Kendall Emerson New York, will discuss "Present Trends in Tuberculosis" Others in the series include

Dr Eugene L Opie New York Importance of Directing the Child and the Young Person Against Tuberculosis
Dr James N Baker Montgomery Ala The Role of the Private Physician in Tuberculosis Case Finding
Dr John B Hawes II Boston The Care of the Patient After the Sanatorium
Dr Don M Griswold Albany N Y Factors in the Control of Tuberculosis
Dr George G Ornstein New York The Pathogenesis of Pulmonary Tuberculosis from the Physician's Point of View

Changes at Wayne University—New appointments to the staff of Wayne University School of Medicine, Detroit, include the following

Arthur H Smith Ph D, professor and head of the department of physiologic chemistry
Dr Gabriel Steiner research professor of neurology and neuropathology
Dr Loren W Shaffer, professor of dermatology and syphilology (part time)
Dr Parker Heath, professor of ophthalmology (part time)
Dr Don W Gudakunst professor and chairman of the department of preventive medicine and public health (part time)
Dr Carey P McCord professor of industrial hygiene (part time)
Henry F Vaughan DPH professor of public health administration (part time)
Dr James M Winfield associate professor of surgery
Dr James L Wilson associate professor of pediatrics
Dr Richard M Johnson assistant professor of medicine
Arthur J Derbyshire Ph D in charge of neuro-anatomy
James M Orten Ph D assistant professor of physiologic chemistry
William M Witheridge M S assistant professor of industrial hygiene and occupational diseases (part time)

MINNESOTA

Personal—On his retirement after ten years as superintendent of the Minnesota School for Feeble-minded at Faribault Dr James Moorhead Murdoch was presented with a gold watch by the Minnesota State Board of Control and other medical superintendents, according to the *Journal-Lancet*—A plaque was placed in the Orono Town Hall at Lake Minnetonka September 27, by the Woman's Club of Crystal Bay, in honor of the late Dr William M Newhall, Long Lake

MISSOURI

Clinical Meeting—The St Joseph Clinical Society began a series of all day programs, September 21, in St Joseph The new set up includes one or two of these all day sessions during the winter and fall in addition to the regular two day program which is an annual spring event of the society—Guest speakers at the first meeting were Drs John S Lund, Rochester, Minn., and Daniel Leritz Sexton, St. Louis The following program was offered

Dr Ora E Whitsell St Joseph Diagnosis and Treatment of Thrombophlebitis and Thrombosis of the Lateral Sinus
Dr Horace W Carle St Joseph Subacute Bacterial Endocarditis
Dr Jacob Kulowski St Joseph Differential Diagnosis of Bacterial Endocarditis
Dr John H Ryan Maryville Diagnostic Encephalography
Dr Sexton Clinical Application of Ovarian Therapy
Dr Frederick Gregg Thompson St Joseph Clinical Treatment of America
Dr William E B Hall St Joseph Deaths in Tetanus—the Importance of Toxin Release
Dr Lund Intravenous Therapy

Society News—At a meeting of the Cass County Medical Society in Harrisonville, September 16, the speakers included Drs William Beckman, Strasburg, on 'Trigeminal Neuralgia', Linn J Schofield, Warrensburg, 'The Doctor in Literature' and George Wise Robinson Sr, Kansas City 'The Problems of Mental Health'—The St Louis Medical Society was addressed September 28 by Drs Thomas P Fundley Jr on "Management of Edema", William E Leighton A Single Trauma as an Etiologic Factor in Cancer, and Charles F Sherwin, 'Principles of Safety in the Treatment of Appendicitis'—Dr Manning E Grimes, St Joseph, discussed "Adaptability of the Various Anesthetics in General Surgery and Obstetrics" before the Buchanan County Medical Society in St Joseph, October 2—Dr Logan Clendenen Kansas City, discussed "The Great Hospitals, Their Past and Their Clinicians" before the Jackson County Medical Society, September 14

MONTANA

Personal—Dr Peter Potter, Butte was guest of honor at a banquet, September 23, given by the Silver Bow County Medical Society, to mark his retirement from practice, November 1 Dr Potter has been president of the Murray Hospital in Butte for many years and has been president of the Butte Chamber of Commerce since 1929

NEBRASKA

Society News—At a meeting of the Southwestern Nebraska Medical Society in McCook, September 16, the speakers were physicians from Denver Drs Osgood S Philpott on 'Commonly Encountered Skin Conditions' Vernon G Jeurink 'Rectal Fistula', Joseph E A Connell, 'Fractures of the Femur,' and Samuel B Potter, 'Subinvolution of the Uterus'—Speakers before the Omaha-Douglas County Medical Society, Omaha, September 28, were Drs Howard K Gray, Rochester, Minn, on "Pathologic Physiology of the Biliary Tract and Its Relation to Surgery", John Harry Murphy, 'Childhood Tuberculosis in Omaha', George E Robertson John Harry Murphy and Herman M Jahr, preliminary report on poliomyelitis patients treated in the county hospital

NEW JERSEY

The Third Annual Martland Lecture—The third annual Harrison S Martland Lecture will be delivered at the Academy of Medicine of Northern New Jersey, November 23 under the auspices of the Essex County Pathological and Anatomical Society The essayist this year will be Dr Harrison S Martland, Newark, who will speak on 'Effects of Poisons' This society established the lecture in 1935 in honor of Dr Martland who is professor of forensic medicine at New York University College of Medicine and medical examiner of Essex County

NEW YORK

Society News—Dr Morris Fishbein, Chicago Editor of THE JOURNAL, addressed the Oswego County Medical Society, Oswego October 14, on 'Medicine and National Policies'—Dr Byrl R Kirklin Rochester, Minn addressed the Broome County Medical Society, Binghamton October 20 on "Diseases of the Intestinal Tract"—Drs Will Cook Spain New York and George Flamm, Brooklyn, addressed the Medical Society of the County of Westchester, October 19, at Grasslands Hospital, Valhalla, on "Bacterial Allergy" and "Pollen Allergy" respectively

District Meetings—The annual meeting of the Eighth District Branch of the Medical Society of the State of New York was held in Olean October 7, with the following speakers among others Drs Francis I Schwentker, Baltimore, on 'The Use of Sulfamidamide in the Treatment of Infections' Cameron Haight, Ann Arbor, Mich, 'Practical and Interesting Phases of Thoracic Surgery' and Charles H Goodrich Brooklyn, president of the Medical Society of the State of New York, "Preventive Medicine"—At the annual meeting of the Fifth District Branch of the Medical Society of the State of New York in Lowville, September 23, the speakers included Drs John C McIntock and George E Beilby, Albany on 'The Problem of Simple Gorter', Herman E Pearce Jr Rochester, 'Management of Peripheral Vascular Disease' and Roscoe C Borst, Utica, 'Management of Urinary Lithiasis'

Dr Ramsey to Succeed Dr Nicoll in Westchester County—Dr George H Ramsey, assistant commissioner for preventable diseases in the New York State Department of Health, Albany, has been appointed commissioner of health

of Westchester County to succeed Dr Matthias Nicoll Jr, White Plains, who will retire on reaching the age of 70 in the spring Dr Ramsey graduated at Columbia University College of Physicians and Surgeons New York in 1917 and later received a degree in public health at Johns Hopkins University School of Hygiene and Public Health He spent several years with the Michigan State Department of Health and from 1926 to 1933 was on the faculty of Johns Hopkins Dr Nicoll became health commissioner of Westchester County in 1930 after having served as state health commissioner for seven years Previously he had been deputy state commissioner for six years and had also served in the New York City Department of Health He graduated from Columbia University College of Physicians and Surgeons in 1892

New York City

Personal—Dr Florence R Sabin of the Rockefeller Institute for Medical Research received the honorary degree of doctor of science, October 8, from Oberlin College, Oberlin Ohio, on the occasion of its centennial observance of the beginning of college education for women and of coeducation

Ordinance Forbids Loud Playing of Radio—New York city has recently made effective an ordinance which forbids the playing of any radio, phonograph or musical instrument in a manner or with such volume, particularly between 11 p m and 7 a m, as to annoy or disturb the quiet comfort or repose of persons in any dwelling, hotel or other type of residence

Graduate Work at New York University—In his annual report issued recently Dr Currier McEwen, assistant dean of New York University College of Medicine, pointed out that graduate education had been developed during the year in the form of short courses and also of courses leading to advanced degrees Three candidates received the degree of doctor of medical science at the June commencement Work toward degrees was done in the departments of forensic medicine, medicine, obstetrics and gynecology, ophthalmology, otorhinolaryngology, radiology and surgery

New Chronic Disease Hospital—Mayor La Guardia laid the cornerstone, October 5, of the partly completed Hospital for Chronic Diseases on Welfare Island Speakers at the ceremony besides the mayor were Dr Willard C Rappleye dean of the College of Physicians and Surgeons of Columbia University, Homer Folks secretary of the State Charities Aid Association, Charles C Burlingham, president of the Welfare Council of New York, and Dr Sigismund S Goldwater, commissioner of hospitals for the city The new hospital, which will cost \$7,000,000 consists of four pavilions for patients, an administration building, a nurses home and a power plant

Medal to Be Awarded for Cancer Education—The New York City Cancer Committee will award the first Clement Cleveland Medal for outstanding educational work in cancer control during the year at a dinner October 27 at the Town Hall Club Dr John C A Gerster, chairman of the committee will preside at the dinner and the speakers will be Dr Stanley P Reimann, Philadelphia Mr Harford Powell Mrs Robert G Mead and Dr Francis Carter Wood Dr Cleveland who died April 16, 1934 at the age of 90 was for many years surgical director of the Woman's Hospital and on the staff of Memorial Hospital for the Treatment of Cancer and Allied Diseases He was a vice president of the American Society for the Control of Cancer in 1922 and had served as president of the New York Obstetrical Society and the American Gynecological Association Members of the award committee are Mrs Mead and Drs George Emerson Brewer, Gerster and Wood The winner of the medal has not been announced

NORTH DAKOTA

Personal—Dr George Alfred Dodds San Haven has been appointed superintendent of the North Dakota State Tuberculosis Sanatorium at San Haven for a two year term to succeed Dr Charles MacLachlan

OHIO

Mr Hooper to Superintend General Hospital—Henry N Hooper recently business manager of the Georgia Warm Springs Foundation has been appointed superintendent of the Cincinnati General Hospital Dr Alfred Friedlander who has been serving as superintendent in addition to his work as dean of the University of Cincinnati College of Medicine will now be chief of the medical staff in charge of all medical and educational work of the hospital

Institute on Syphilis at District Meeting—A meeting of the Fifth District Medical Society in Cleveland, October 8, was devoted to an institute on syphilis. Clinics were conducted in the morning and early afternoon at Lakeside Hospital. Later came a round table discussion on diagnosis and treatment of transmissible syphilis, led by Drs Robert E Barney, Earle Netherton and Clyde L Cummer, and a showing of the sound motion picture on syphilis prepared by the American Medical Association and the U S Public Health Service. At an evening meeting under the auspices of the Academy of Medicine of Cleveland Dr Raymond A Vonderlehr, in charge of the division of venereal disease U S Public Health Service, Washington, D C, spoke on 'Public Health Control of Syphilis' and Dr Joseph Earle Moore, Baltimore, 'Treatment of Nervous System Syphilis'.

Society News—Drs Max M Zinniger and Tom D Spies, Cincinnati, addressed the Stark County Medical Society, Canton, September 14, on "Diagnosis and Surgical Treatment of Lesions of the Bile Ducts" and "Diagnosis of Pellagra" respectively.—Drs Charles W Pavey, Columbus, and James V Seids, Cleveland, were the speakers at a meeting of the Sixth Council District Medical Society at Millersburg, September 15, on 'Eclamptic Convulsions' and 'Gallbladder Disease' respectively.—Dr George W Crile, Cleveland, addressed the Summit County Medical Society, Akron, September 14, on 'Clinical Problems of Essential Hypertension'.—Dr Alfred W Adson, Rochester, Minn, addressed a joint meeting of the Mahoning County Medical Society, the Cleveland Oto-Laryngological Club and the Pittsburgh Oto-Laryngological Society in Youngstown, September 29, on "Neurological Complications of Sinus and Mastoid Infections". Dr Louis J Karnosh, Cleveland addressed the Mahoning County society, September 21, on 'Three Mileposts of Modern Psychiatry: Fever Treatment, Vitamin Therapy in Deficiency Diseases, and Insulin Shock for Dementia Praecox'.—Dr Thomas F Ross, Columbus, addressed the Ross County Medical Society, Chillicothe, September 1, on 'Toxemias of Pregnancy'.

OKLAHOMA

Professor of Orthopedic Surgery Appointed—Dr Paul C Colonna, clinical professor of orthopedic surgery, New York University College of Medicine, has been appointed professor of orthopedic surgery at the University of Oklahoma School of Medicine, Oklahoma City. He will have charge of the orthopedic services at the University Hospital and the Crippled Children's Hospital. Dr Colonna graduated from Johns Hopkins University School of Medicine, Baltimore, in 1920. In New York he has been associate orthopedic surgeon to the Hospital for Ruptured and Crippled and Bellevue Hospital.

PENNSYLVANIA

Society News—Dr Samuel S Allen Jr, Pittsburgh, addressed the Cambria County Medical Society, Johnstown, October 14, on "Head Injuries".—Dr Eldridge L Eliason, Philadelphia, addressed the Lebanon County Medical Society, Lebanon, October 12, on "Surgical Conditions of the Biliary Tract".—Dr Harry M Margolis, Pittsburgh, addressed the Indiana County Medical Society, Indiana, September 23, on "Management of the Chronic Arthritic Patient".—Dr Cortlandt W W Elkin, Pittsburgh, addressed the McKean County Medical Society, Bradford, September 21, on 'Some Medical Aspects of Gallbladder Disease'.

Institute on the Exceptional Child—The fourth annual Institute on the Exceptional Child, sponsored by the Child Research Clinic of the Woods Schools, Langhorne, will be held October 26, with the following program:

Dr Louis A Lurie, Cincinnati, Endocrinology as It Relates to the Understanding and Treatment of the Exceptional Child
Dr Fritz B Talbot, Boston, The Present Status of Mongolism
Dr Paul F Schilder, New York, Psychological Implications of Motor Development in Children
Esther Lloyd Jones, Ph D, New York, Training Opportunities for Workers with Exceptional Children

Dr Baldwin L Keyes, Philadelphia, will preside at the morning session and Edgar A Doll, Ph D, Vineland, N J, at the afternoon meeting.

Philadelphia

Society News—At the first fall meeting of the Philadelphia County Medical Society, September 22, forty-nine physicians of the First Council District received certificates honoring them for fifty years or more of medical practice.—Two James M Anders lectures were delivered before the College of Physicians of Philadelphia October 6 by Henry C Sherman, Ph D, New York, on 'Optimal Nutrition as a Scientific Concept' and

an Economic Problem' and Charles Edward A Winslow, Ph D, New Haven, Conn, 'Housing and Health'.—Andrew J Ramsay, Ph D, and Dr James F McCaher addressed the Obstetrical Society of Philadelphia, October 1, on "Anatomical Distribution of the Rete Ovarii in Normal Ovaries" and "A Consideration of the Rete Ovarii with Relation to Male Secondary Sex Characteristics in Women" respectively.—Among speakers before the Philadelphia Academy of Surgery, October 4, were Dr Isidor S Ravdin, Samuel Goldschmidt, Ph D, and Harry M Vars, Ph D, on 'Factors Conditioning the Occurrence or Liver Necrosis Following the Use of Volatile Anesthetics'.

Faculty Changes at University of Pennsylvania—Dr Earl D Bond has been appointed vice dean for psychiatry in the Graduate School of Medicine of the University of Pennsylvania and Detlev W Bronk, Ph D, to a similar position in neurology. Dr Bond is professor of psychiatry at both schools of medicine at the university and Dr Bronk is professor of neurology in the graduate school and Eldridge Reeves Johnson professor of biophysics in the school of medicine. Dr Leon Herman has been appointed professor of urology in the graduate school and Dr John H Jopson retires with the rank of emeritus professor of surgery. Other changes include:

Dr Eugene P Pendergrass, professor of radiology
Dr Joseph C Yaskin, clinical professor of neurology
Dr John P Scott, associate professor of pediatrics
Dr Albert E Bothe, assistant professor of urology
Dr Robert A Kimbrough Jr, assistant professor of obstetrics
Dr Jesse T Nicholson, assistant professor of obstetrics

In the University of Pennsylvania School of Medicine the changes include:

Dr Roy G Williams, associate professor of anatomy
Dr Alexander G Fewell, associate professor of ophthalmology
Dr Benjamin F Baer Jr, associate professor of ophthalmology
Dr William F Moore, assistant professor of clinical bronchoscopy and esophagoscopy
S Culver Williams, Ph D, assistant professor in anatomy
Harry E Morton, Sc D, assistant professor in bacteriology
Dr Thomas C Kelly, assistant professor in pediatrics
Dr Herman Beerman, assistant professor in dermatology and syphilology
Dr Wilfred E Fry, assistant professor in ophthalmology
Maximilian Ehrenstein, assistant professor of chemistry

SOUTH CAROLINA

Society News—Dr Paul H Culbreath Jr, Ellenton, among others, addressed the Ridge Medical Society in Batesburg, August 16, on congenital hemolytic jaundice.—Drs Leo F Hall and George C Battle, State Park, addressed the Kershaw County Medical Society at the South Carolina Tuberculosis Sanatorium, State Park, July 14, on 'Phrenic Nerve Interruption in Tuberculosis' and "Intrapleural Pneumolysis" respectively.

Specialty Society Meetings—The Urological Association of South Carolina held its annual meeting in Columbia, October 13, with the following speakers at an afternoon session: Drs Stephen W Davis, Charlotte, N C, on 'Fever Therapy in the Treatment of Gonorrhea'; Paul W Sanders Jr, Charleston, 'Acute Suppurative Nephritis'; Mordecai Nachman, Greenville, 'Management of Urologic Conditions in Children'. In the evening session the speakers were Drs Jefferson C Pennington, Nashville, Tenn, on 'Management of Calculi in the Upper Urinary Tract' and Edgar G Ballenger, Atlanta, 'Management of Tumors of the Bladder, Both Benign and Malignant'.—Dr Isaac A Abt, Chicago, was the guest speaker at a meeting of the South Carolina Pediatric Society in Columbia, October 11. He spoke at an afternoon session on 'History of the Vitamins' and at an evening meeting with the Columbia Medical Society on 'Management of the New Born Infant'.

VIRGINIA

Society News—Speakers at the first fall meeting of the Richmond Academy of Medicine, September 28, were Dr Richard H Overholt, Boston, on 'The Surgical Treatment of Primary Carcinoma of the Lung'; Marshall P Gordon Jr, Richmond, 'Sulfanilamide in the Treatment of Gonorrhea'; and Dean B Cole, Richmond, 'Twelve Years' Experience in the Use of Iodized Oil'.

Pediatric Clinician Appointed—Dr Robert B Hightower, Boston, has been appointed clinician in pediatrics in the department of clinical and medical education of the Medical Society of Virginia to succeed Dr Jay M Arena, resigned. Dr Hightower was graduated from the University of Virginia Department of Medicine in 1932 and has recently been resident at the Children's Hospital, Boston. He will come to Virginia December 1. Dr Arena is now on the faculty at Duke University School of Medicine, Durham, N C.

WASHINGTON

Public Health Officers—Dr Cecil R Fargher, Wenatchee health officer of Chelan County, was elected president of the Washington State Public Health Association September 11, at its annual meeting in Tacoma. Dr Fargher succeeds Dr Samuel M Creswell, health officer of Tacoma. Roy M Harris, state health engineer, was named secretary.

Society News—Drs Thomas D Thompson and Alfred O Adams addressed the Spokane County Medical Society, Spokane, September 9, on 'Injuries About the Ankle Joint' and 'The Technique of Transplanting Split-Thickness and Full-Thickness Skin Grafts' (motion picture) respectively. The King County Medical Society was addressed October 4 by Drs Delbert H Nickson, Seattle, on 'Salivary Gland Tumors and Kenneth K Sherwood Kirkland 'Neuritis and Vitamin B Therapy.' The society was addressed September 20 by Dr Arthur E Wade, Seattle, on 'School Medicine in Relation to Private Practice' and Dr Walter Raymond Jones Seattle, 'Local Immunity in Gonorrhea Its Relation to Cure.' Dr William W Bauer, director, Bureau of Health and Public Instruction American Medical Association Chicago will be the speaker, October 25, on 'The Place of the Doctor in the Community Health Program.'

GENERAL

The Edward A Filene Will—According to the New York Times the Good Will Fund, recently incorporated charitable and educational foundation receives the major share of an estate exceeding \$2,000,000 under the will of the late Edward A Filene, Boston. The fund was pledged to research and education, to further the welfare of mankind improvement of health conditions for workers improvements in medical care and research, and education concerning causes of poverty.

Study of Environmental Factors in Leprosy—The Leonard Wood Memorial (American Leprosy Foundation) announces that Dr George M Saunders Kingston Jamaica, B W I recently director of the Laws Commission of the British West Indies under the auspices of the Rockefeller Foundation, has been appointed to make a special world-wide study of the environmental factors that affect the lives of lepers and that might assist in the treatment of the disease. The memorial is seeking additional funds to carry on this enlarged study.

Bequests and Donations—The following bequests and donations have recently been announced:

Mount Sinai Hospital New York \$196,102 under the will of Mrs Amelia A Meyers for a new building or a semiprivate pavilion. Montefiore Hospital and the United Hospital Fund are to receive remainder interests in \$50,000 and \$40,000 trusts respectively.

Harlem Eye Ear and Throat Infirmary New York \$1,500 by the will of Carrie E Karstens.

Johns Hopkins University and Johns Hopkins Hospital Baltimore \$30,000 Hospital for Women of Maryland \$5,000 Hospital for Consumptives at Towson Md. \$10,000 by the will of Miss Amelia Marburg.

Jewish Hospital Philadelphia \$10,000 through the Federation of Jewish Charities to endow a bed. Eaglesville Sanitarium for Consumptives \$5,000. St. Luke's and Children's Hospital and St. Christopher's Hospital for Children Philadelphia Children's Seashore House Atlantic City N J \$1,000 each. Children's Heart Hospital Skin and Cancer Hospital Philadelphia \$500 each by the will of the late Joseph Wasserman.

Lincoln General Hospital Lincoln Neb. \$200,000 in cash and the income from the residue of an estate valued at more than one and a half million dollars.

Norwalk Memorial Hospital Norwalk Ohio \$5,000 by the will of the late Mrs C A Paul.

St. Luke's Hospital New York an interest valued at \$95,447 in the estate of the late Dr Edward B Dench.

Society News—Abel Wolman, chief engineer Maryland State Department of Health Baltimore was chosen president-elect of the American Public Health Association at its annual meeting in New York, October 5-8 and Dr Arthur T McCormack, Louisville Ky., was inducted into the presidency. Vice presidents elected were Drs John L Rice New York John T Phair Toronto Ont., and Domingo Ramos Havana, Cuba. The next meeting will be in Kansas City Mo. Officers elected at the annual session of the American Congress of Physical Therapy in Cincinnati September 20-24 are as follows: Drs Frank H Kruseh Rochester Minn president-elect William H Schmidt Philadelphia Nathan H Palmer New Orleans, Fred B Moor, Los Angeles Kristian G Hanson New York and Miland E Knapp, Minneapolis all vice presidents and Richard Kovacs New York secretary. Dr Edward A Meyerding St. Paul was elected president of the Mississippi Valley Conference on Tuberculosis at its twenty-fourth annual meeting in Dayton Ohio September 23-25. Mrs Theodore B Sachs Chicago director of the Chicago Tuberculosis Institute was made vice president and Mr A W Jones St. Louis, was renamed secretary.

FOREIGN

Society News—The sixth International Congress of Radiology will be held in Berlin in 1940, it was decided at the recent congress in Chicago. Dr Hermann Holthusen, Hamburg, Germany, was elected president for the next congress.

Americans on Gastro-Enterology Program—At the second International Congress on Gastro-Enterology in Paris, September 13-15, the following American physicians participated in discussions, among others: Drs Joseph Felsen Henry A Rafsky, Max Einhorn, Roy Upham Anthony Bassler Samuel Weiss, all of New York. Max Thorek and Rudolf Schundler, Chicago. Daniel N Silverman and Abraham L Levin New Orleans. Solomon Ben-Asher, Jersey City, N J, and Hyman I Goldstein, Camden, N J.

Congress of Obstetrics and Gynecology—Subjects for discussion at the International Congress of Obstetrics and Gynecology to be held in Amsterdam, May 4-8, 1938, are announced as follows: eclampsia, thrombosis and embolism and hormones. These will be discussed at the morning meetings and afternoons will be devoted to papers on a variety of subjects. Contributions to the program may still be accepted according to an announcement from the secretary, Dr F C van Tongeren, University Clinic for Obstetrics and Gynecology Amsterdam, W, Holland. Dr A H M J van Rooij, Amsterdam, is president.

CORRECTION

Young & Rubicam Not Concerned in Cutasy Laboratories, Inc.—In THE JOURNAL for October 2, page 1142, appeared a statement to the effect that 'Mr John Orr Young, president and treasurer of the Cutasy Laboratories, Inc., is also president of Young & Rubicam, Inc., an advertising agency.' This statement is incorrect. Mr John Orr Young has not any business connection with, or financial interest in, the firm of Young & Rubicam, Inc. He ceased to be president in June 1927.

Government Services

New York Free from Bovine Tuberculosis

The state of New York was officially designated by the U S Department of Agriculture as a modified accredited area, indicating its practical freedom from tuberculosis of cattle, October 1. New York is the forty-sixth state in which all counties are in the modified accredited status, indicating that bovine tuberculosis has been reduced to less than 0.5 per cent as shown by the tuberculin test. According to a release from the department of agriculture there are no counties east of South Dakota that have not been placed in this classification, and only one other state, California in which there are any nonaccredited counties. The eradication of bovine tuberculosis was begun in New York in 1919 and the first county, Essex, was designated as a modified accredited area in 1924. Since that time some counties have been added to the list almost every year, but during the calendar year 1937 twenty-six counties were added. Oneida being the last county.

Dr Hektoen to Be Director of Advisory Cancer Council

Dr Ludwig Hektoen, Chicago, has been appointed executive director of the National Advisory Cancer Council. It was announced October 16. The council was recently organized in conformity with the National Cancer Institute Act which provides for the erection and administration of a national cancer institute at Bethesda Md. The law also provides for the expenditure of \$700,000 annually in the campaign against cancer. The new cancer institute will function as a division of the U S Public Health Service in the National Institute of Health. It will be the liaison corps for the nation between all official and voluntary participants in the fight on cancer. With the approval of the advisory council it is hoped that the significant researches carried on in the institute of health for the past several years under the direction of Dr Carl Voegtlin will be expanded and improved. Dr Roscoe R Spencer, senior surgeon U S Public Health Service known for his work on Rocky Mountain spotted fever, will assist Dr Hektoen on matters of administration of the new project. The personnel of the advisory council was announced in THE JOURNAL October 16, page 1287.

Health Campaign Launched by the Prime Minister

A national campaign to encourage the wider use of the health services is being organized by the Central Council for Health Education with the cooperation of the Ministry of Health and the board of education. It will be officially launched by the prime minister and will be continued for six months. The minister of health and the president of the board of education have issued the following joint message to the local authorities: Over a number of years and particularly in the last three decades, the government, the local authorities, voluntary organizations and workers, and the medical and allied professions, have been building up a network of health services. But we should not be justified in resting on our oars. The prospective beneficiary, too, has his or her part to play. Some of the services are not being used to the extent which we should desire, and the help of the family doctor and of the diagnostic and treatment facilities at his disposal is often invoked too late. For this reason the prime minister is launching a national campaign to appeal to all, and especially to parents and others who have charge of children, to see that every one has the fullest opportunity of benefiting by the numerous health facilities at his call. The authorities hope for the cooperation of all men of good will. The month of October will be used to arouse public interest in the health services in general, and health weeks and exhibitions will be arranged. In November and December increased use of the services available for mothers and children will be urged. In January the object will be increased support for the school health service, to encourage parents to make greater use of the milk in schools scheme and to pay greater attention to the advice of the school doctor and dentist. In February wider use of the facilities available for adolescents and adults, particularly those relating to tuberculosis and venereal disease, will be urged. March will be devoted to the facilities for physical training and recreation. Extensive use will be made of posters and films.

The board of education has published two handbooks entitled "Recreation and Physical Fitness for Girls and Women" and "Recreation and Physical Fitness for Youths and Men." The books have been compiled in accordance with the board's new policy on physical education, a chief element of which is insistence on the provision in schools of better means of exercise and on the acquisition of playing fields with appointment of instructors. The handbooks are excellent for their purpose and combine the strategy and tactics of physical culture with experience in a way which has not previously been available. It is insisted, to begin with, that enthusiasm for fitness must exist in those seeking it and must make itself effective through leadership. In a foreword Sir Arthur MacNalty, chief medical officer of the board of education, says: "It is essential for the leaders of youth to appeal to the young men around them to take a pride in becoming physically fit. At the same time one part of the body should never be developed at the expense of another, and the body should never be developed at the expense of the mind and spirit. The Greek ideal was a balanced rhythm of life, a golden mean, and excess whether of study or gymnastics, is disharmony and to be avoided." He urges that all depends on the leader, who must concern himself with the spirit which pervades the whole meeting. In the book for youths and men the exercises are divided into three groups: free standing and floor exercises with a bite in them, stronger exercises, some of them with apparatus—jumping, vaulting and agility exercises. The teaching and organization of team ball games, national

team games, general athletics, swimming, dancing, boxing, climbing and wrestling are fully dealt with. A chapter on camping reflects the popularity just now of camping holidays.

The Health of the Medical Student

It is curious that, while so much has been done to promote health, the unhealthful conditions under which the medical student often works have only recently received attention. The *Lancet* has a long article in its students' number under the caption "Increasing Attention to Be Paid to the Health of Medical Students." It quotes the recent remark of a dean of a medical school: "The student's life makes a great demand on his general health, so that by the time he has held a resident appointment he is liable to fall by the way." At the turn of the century a majority of the housemen of a London hospital broke down with tuberculosis. That this was due to the way they were living rather than to any inherent weakness was shown by the fact that most of them regained health. The circumstances of the medical student's life are peculiarly trying. While most other students graduate after three years and then have a period of relaxation, he has first a preclinical period which, in effect, is graduation in science and then embarks on another period of three years or more in which the risk of infection is added to the ordinary strain of student life. Dr. D. Arcy Hart found that roentgenograms of the chest showed more evidence of progressive tuberculosis in the later than in the earlier years of medical training, and the increase was greater in medical students than in dental and law students. The *Lancet* refers to the fact that young adults who do not react to tuberculin are more susceptible than those who do. This has been shown by Scandinavian experience of nurses. It therefore suggests that students who do not react should be excluded from contact with tuberculosis unless vaccination with BCG will turn them into reactors. Or they might submit to roentgenography of the chest, as is now being done at University College Hospital, London, and on a larger scale by the Royal College of Physicians. As a result of the first examination of 300 students, 232 were told to return in a year, and sixty-three within a shorter time. Four had some restriction placed on their work and one was advised to go at once to a sanatorium. The examination took place last February and up to the present time four cases of progressive pulmonary tuberculosis have been detected.

In a letter to the *Lancet*, Sir Ernest Graham Little (dermatologist and member of Parliament and of the senate of London University) agrees as to the strain on the health of the medical student, entailed by what is practically continuous study for six or seven years without a break, in an atmosphere which too often is unhealthful. He protests against the scandal of a swollen medical curriculum crying out for diminution but actually receiving extension. The new curriculum will make it necessary for the medical student to forego vacations entirely in the last three years—the hospital period in which he is most exposed to infection. At the same time clinical teaching, long the pride of English medicine, has been sacrificed to pseudo-scientific claims.

On the other hand, Mr. Girling Ball (genito-urinary surgeon and dean of St. Bartholomew's Hospital) is more optimistic. He admits that the medical curriculum makes considerable demands on the student's time and energies. He got one of his colleagues to select 100 medical students and ask them for their personal views. Almost all said that they were not overworked. Mr. Girling Ball finds the question whether the health of students generally is adversely affected by their work hard to answer. With the object of investigating this point a student health service was established at the hospital. The following figures are interesting. During the past ten years 1,028 students have entered St. Bartholomew's, ten have died and eight have failed to qualify through ill health. Of the ten deaths six were the result of accident. Thus the number who had to relinquish

medicine owing to ill health was small. Numerous facilities for exercise are afforded to the students. There is little teaching on Wednesday afternoons and none on Saturdays. Mr. Girling Ball therefore does not believe that the strain on any normal student is such as to endanger his health. It should be borne in mind that he speaks only from the experience of his hospital, where the arrangements are excellent.

Sept 25 1937

Decrease in Number of Students Seeking Honorary Diplomas

Until the passage of the Armbruster law in 1933, many foreign students entered the French medical schools as candidates for the university diploma (*diplome universitaire*). This did not confer the right to practice here but was of purely honorary character and could be used as a stepping stone to a license to practice, if the examinations leading to the French bachelor of arts degree were passed. The requirements are so rigid now that those who are not born in France or its colonies or have not been naturalized for at least ten years cannot be candidates for a state license even though they possess both the university diploma and the bachelor of arts degree. Consequently the number of foreign students is constantly decreasing. Prof. Henri Hartmann of Paris, president of the association to encourage foreign physicians to visit or study in France, announced recently that in 1929 there were 280 foreign medical students here. This number decreased to seventy-one in 1935 and to thirty-one in 1936. There are a number of reasons for this drop such as the world economic crisis, difficulties of taking money out of certain countries, protests by French medical men against invasion by foreigners, and especially better facilities for medical instruction in countries like those of Central and South America and eastern Europe, which formerly sent a great many students to French medical schools and physicians for postgraduate courses.

Medical Examination of First Year Students

As in 1935 and 1936, the Faculty of the Paris Medical School has arranged for examination of all students entering the preliminary medical year this fall. Although such an examination is not obligatory, a plea has been made by the dean for all students to appear as soon as they are notified. Too many young students become ill during their first or second years as the result of being exposed to pulmonary tuberculosis; hence the preliminary examination aims particularly to detect cases showing incipient lesions or negative tuberculin reactions before they begin their medical studies. If the student so requests, the results of the examination will be sent to their parents or family physician.

Prize for Article on Social Aspects of Tuberculosis

The Leon Bernard Foundation of the International Union Against Tuberculosis announces that the biennial prize of 2,500 francs in memory of Prof. Leon Bernard will be awarded during 1938. The subject chosen for the competition is "Social Aspects of Tuberculosis" and articles must be written in either French or English, not to exceed 10,000 words. Those who desire to send articles can secure information by writing to the Secretary of the International Union Against Tuberculosis, 66 Boulevard St. Michel, Paris XI. The articles must be in the hands of the executive committee before May 1, 1938.

Aeronautic Medicine Congress

This year's meeting was held July 6 and 7 at the Faculté de médecine de Paris. A report was made by medical officers of the air service on the mode of transport of the sick and injured by airplanes in the French colonies. Since 1920 6,820 patients have been thus transferred to base hospitals. Use is

also made of airplanes for inspection of widely scattered army centers by officers of the health service and for carrying serums and drugs to isolated stations, at times with the aid of parachutes. In May an incipient epidemic of bubonic plague was checked in thirty-six hours by sending serums and vaccines a distance of 580 miles by airplane.

In the Section on Aeronautic Medicine, Dr. Garsaux spoke on recent discoveries in the physiology of this field. A normal person is well able to tolerate an increase of the present velocity of ascent and descent of planes. In order to rise above an altitude of 12,000 meters it is indispensable for the aviator to have an outfit similar to that used by deep sea divers.

Medical Problems in the French Colonies

The July 6 meeting of the Académie de médecine was devoted to medical problems in the French colonies, which are scattered all over the world and are more numerous than is generally thought.

The first paper was by Bezançon and Arnould on "Newer Aspects of Tuberculosis Among Negroes." During the World War, Borrel had found that this disease in soldiers from the colony of Senegal greatly resembled the forms observed in children and in guinea-pigs. Acute onset with localization in the cervical lymph nodes was very common. The severity of the infection was probably the result of a lack of previous immunization. Later studies, however, have shown that tuberculosis is in reality not more frequent in Negroes coming from the colonies than among other persons living under poor hygienic conditions. At La Rochelle, in the southwestern part of France, a large number of recruits from Senegal were placed in an army camp in which every precaution was taken to detect and isolate those already infected with tuberculosis. In addition, warm clothing, ample nourishment, well heated barracks and comfortable uniforms were provided. The result has been that the fear of widespread tuberculous infection among Negro troops has entirely disappeared.

The second paper, by Marchoux, was on "The Antileprosy Fight in the French Colonies." For a long time little attention was paid to the disease, the lepers were regarded more as criminals and put in prisons instead of in hospitals. The result was that they hid themselves and were more of a menace than ever. Since the third International Conference on Leprosy, held in 1923 at Strasbourg, a special department for this disease has been created in the French ministry for colonies. Dispensaries have been established in every colony, and visiting nurses instruct lepers at their homes how to avoid contamination of their families and how to apply dressings to ulcerating lesions. Advanced cases are sent to hospitals where they can be frequently seen by medical officers. It is hoped that a decided reduction will be the result of these more modern measures.

The third paper was on "Sanitary Protection," by Lasnet, and the fourth on the "Organization of Colonial Medicine," by Dr. Sorel, who stated that more than 800 physicians were now engaged in fighting disease in the colonies. As an example of their excellent work, statistics were cited of a decrease in the mortality of cases of trypanosomiasis in equatorial French Africa from 20 per cent to 0.6 per cent.

The last paper was by Achard, on "Medical Instruction of Natives in the Colonies." Although it is desirable to have physicians who are not natives of the colonies, an effort should be made to have as their aids medical men who were born in the colonies. They are better acquainted with the errors in hygiene and food and have more influence in convincing the natives regarding the necessity of taking treatments. There has been some objection to having native physicians, but Achard believed that this could be overcome if their work was subjected to frequent supervision. Great progress has been made in one of the provinces of Indo China in establishing a medical school for native young men, who have been found eager to

learn In Madagascar, a large French colony, the graduates of the local medical school are given government positions for six years and are then allowed to practice independently

Spontaneous Benign Pneumothorax

Twelve cases of benign spontaneous pneumothorax are reported by Castex and Mazzei of Buenos Aires in the January issue of the *Archives medico-chirurgicales de l'appareil respiratoire*. All were male patients, the majority between 20 and 25 years of age. The pneumothorax is total and may follow exertion or occur without any effort. The films reveal small bullae-like clear areas, with borders so fine that they resemble soap bubbles, in any area of the visceral pleura. They are termed "subpleural bullae" by the authors and vary greatly in size and number. The prognosis is favorable, as a rule, but resorption may take place slowly in some cases. The etiology of these bullae is still dark, but they do not bear any relation to tuberculosis.

Chronic Myelogenous Leukemia in Machinery Oilers

Sabrazes and Bideau report a case in the May 30 issue of the *Gazette medical de Bordeaux* in which there seemed to be an etiologic relationship between myelogenous leukemia and a lubricant, containing benzene, as employed by a machinery oiler 20 years of age. His hands and face, during working hours, over a period of three years, were constantly covered with oil. Nearly all commercial oils contain traces of benzene. The heavier the oil, the more it contains. The clinical picture in the case reported by the authors was that of a myelogenous leukemia with splenomegaly and slight involvement of the lymph nodes. The authors believe that there ought to be a law against the use of oil, for the lubrication of machinery, which contains too high a percentage of benzene hydrocarbons.

Professor Lambret Honored

A distinguished surgeon of northern France, Professor Lambret, has just received a much merited recognition of his services as director of the Anticancer Center of Lille, where he is also professor of surgery, in being appointed a grand officer of the Legion of Honor.

BERLIN

(From Our Regular Correspondent)

Sept 5, 1937

Effects of Alcohol on Drivers of Motor Vehicles

Experimentation on the effects of alcohol on drivers of motor vehicles was carried on by the Institute of Medical Jurisprudence at Wurzburg University with the cooperation of the traffic authorities. The tests showed to how great an extent drivers are influenced by alcohol. Six motorcyclists submitted to the tests. First, while they were perfectly sober, the drivers were given four problems to solve. Then, after ingestion of alcohol, they were required to repeat the solutions. The principle established by previous experimentation, namely, that an influence exists if the alcohol value of the blood has reached 07 or 08 per cent was followed. Twenty-four other individual tests were given subsequent to still further ingestion of alcohol. All the motorcyclists exhibited an impaired efficiency after indulgence in alcohol. Five of the six drivers increased their speed considerably. Thence it was concluded that after even moderate indulgence in alcohol a driver is more inclined to speed than if in a state of perfect sobriety and accordingly the greater the amount of alcohol consumed the greater will be the element of danger. In three of the six drivers the reaction time was observed to be considerably lengthened. None of the drivers were drunk in the popular sense of the term at any time during the experiment, the average alcohol value in the blood at the completion of the tests was 0.12 per cent.

The Sex Hormones

For biologic evaluation of testis preparations, the cock's comb method has become the standard procedure. Loewe and Vein in the interests of further standardization, have made interesting studies based on changes that follow castration: atrophy of the vesicular glands, flat and cell-deficient epithelium, scanty and chromophobic secretion. Treatment with androgen effected a recession of all these sequels of castration. Whereas at the outset of the investigation the cock's comb test, as the simplest procedure, was mostly relied on, the determination of efficacy by means of the gland test came to be generally adopted because of its greater biologic importance. Dr. Dirscherl discussed this topic in the Medical Society of Frankfurt on the Main. Dirscherl found that besides the already recognized effective substances there was a new substance for which the group term "vesine" was suggested. The vesines differ from the better known androgens in that they exert a stronger effect on the vesicular glands. Conversely, they appear to have practically no influence on the combs of capons. A vesine is found combined with estrogen in the urine of mares. The urine of mares also contains a prohippovesine which by hydrogenation becomes a hippovesine B productive of powerful glandular reactions. The latter substance may be identical with hippovesine A. Vesines are also encountered in wool fat and in extracts of cinchona bark. Purification has thus far yielded crystallized fractions which, if used in the vesicular gland test are more effective than testosterone.

Professor Seitz, ordinarius in gynecology, called attention to the fact that the problem ought also to be considered from the phylogenic point of view if the remarkable reciprocal interrelation of male and female sex hormones is to be properly understood. Estrogen is present in the lowest forms of life in plants, bacteria, protozoa. It is also found in coal, unchanged after hundreds of thousands of years. In other words, it is present long before the two sexes become differentiated. In addition to its specific sexual influence it produces a series of nonspecific effects both in man and in the other mammals. In lower animal species, without specific sexual differentiation, it is first of all a hormone of growth. Only higher in the evolutionary scale does it exert specific sexual influence. It is thus a hormone of primitive growth and primitive sex.

Genetic Studies of the Finger Ridges

Dr. Duis of the Institute of Racial Biology at Koebigsberg recently reported to the local society of scientific medicine the results of his genetic studies of ridges on the hands and fingers. The structure of the delicate system of the cristae cutis which covers the surface of the hands and feet, depends on embryologic factors of a proved hereditary nature. That which is inherited is not the particular combination of ridges but rather the morphologic condition of the embryonal period on which the development of the standard type depends. This genetic biologic observation does not diminish the importance of the cristae cutis for the criminal identification service, since the hereditary determination of the embryonal condition by no means precludes variation therein. Study of the embryologic factors elicited an interrelation of the degree of curvature in the finger pads and the type (Bonnevie). This interrelation in turn is dependent on the thickness of the epidermis and on occasional infiltration of fluid cushions in the embryonal finger pads. Since the cushion of the thumb side and that of the little finger side of the hand are separately inherited, the quantitative value (as an expression of the number of ridges per type) is determined by three hereditary factors each independent of the other, namely: the factor of general cutaneous elasticity and two curvatures. Accordingly it becomes possible to determine the genetic type and this principle has already been applied in forensic determinations of paternity. Similarly the ridge type of the palms have been proved heritable. Racial differences of anthropologic significance are also exhibited in the distribution

of the hand and finger ridges, for example, in the difference between northern Europeans and Mongolians or in the papillar affinity of the Eskimo group with the European racial branch. The flexor ridges of the hand originate independently of the muscular and osseous development as demarcations of the pads in phylogenically produced cutaneous areas.

The Importance to Public Health of Treatment of Strabismus

Dr H Harms recently addressed the Berlin Medical Society on the importance to public health of a proper treatment of strabismus. Concomitant strabismus is not a sign of degeneration but often occurs in healthy persons, even in those of superior endowment. The condition is apt to produce a sensory disturbance of the stereoscopic vision which renders the persons thus affected unfit for many occupations. The most serious result is an asthenopia of the diverted eye which may even end in unilateral blindness. According to statistics, 4 per cent of the population of all European countries are strabismic and some 50 per cent of this number are weaksighted in one eye. This means that in Germany from around 2 000 000 to 2,500 000 persons are strabismic and from 1,000,000 to 1 300 000 affected with unilateral weaksightedness.

Senecio Poisoning

Since 1926, when Wilmott and Robertson published a paper in the *Lancet* on senecio poisoning it has been known that contamination of wheat by the immature florets of various species of bladderwort may cause a fatal hemorrhagic panhepatitis in human beings. From time to time such cases of senecio poisoning are reported. Recently a family of five a husband and wife and three children, were admitted to a hospital with the characteristic signs of senecio intoxication. These are progressive malnutrition with enlargement of the liver and spleen, transient jaundice, definite portal obstruction and rapidly accumulating ascitis. One of the patients has since died and the necropsy showed the typical lesions in the portal lobules, hemorrhagic infiltration and cirrhosis, pathologically very similar to what is found in cases of amanita poisoning and in eclampsia. These cases are now the subject of intensive investigation, for the syndrome is of particular interest as it is not quite clear in what manner the patients have been poisoned. The known alkaloids of the senecio plant are volatile, and prolonged feeding of experimental animals with the contaminated wheaten flour has not been followed by symptoms indicative of poisoning such as is seen in horses, for example, by the green plant. It is probable that some familial or other factor is involved, for clinically the cases now in the hospital remind one strongly of the familial, juvenile type of interstitial hepatic cirrhosis described by French writers.

An Afrikaans Medical Faculty

There are at present two faculties of medicine attached to universities in the Union of South Africa. The elder is the faculty of medicine of the University of Cape Town, the younger, that of the University of the Witwatersrand at Johannesburg. Together they turn out about sixty newly qualified physicians every year. The annual wastage in the medical profession through death, departure or other causes is about fifty and allowing for the increase in the population it may be estimated that an annual recruitment of 100 for the profession is not economically excessive. When our medical schools started, fears were expressed that the profession would soon be overcrowded and that the new graduates would find little or no work to do while their numbers would severely handicap already established practitioners who already had difficulties in making both ends meet. Experience has however, completely falsified these pessimistic expectations. The grad-

uates of our medical schools have found no difficulty whatever in getting remunerative employment, and indeed the demand for doctors is as great and as lively today as it was some years ago. This year's entry for the medical course at both universities with faculties of medicine exceeds last years in numbers, and teachers of medical subjects are seriously perturbed about the size of the classes they have to handle. There is abundant clinical material, but it is still, to a large extent, unorganized, with the result that comparatively little of it is available for regular clinical teaching. To some extent this difficulty will be overcome, as far as the Cape Town University is concerned, as soon as the big new hospital on the Groot Schuur estate is open.

The medium of instruction at both schools is English, and medical curriculums are based largely on English models. It is now increasingly urged, partly as the result of the rapid rise of Afrikaans, the third official language of the country, and partly for the satisfaction of the growing sense of nationalism, that a separate medical school, with Afrikaans as its medium of instruction, should be established, preferably at Pretoria, which has a good modern hospital and has recently been the scene of intensive industrial development. It is argued that such a school will complement the existing two schools by concentrating more actively on continental methods and will supply the requirements of South African medical students who now go to Dutch or German schools for their professional study. The suggestion has been received with mixed feelings by the profession, who, while fully realizing the justice of the demand for professional education in Afrikaans, prefer that such instruction should be given in parallel classes in the existing schools rather than that a third medical school should be established in competition with those at Cape Town and Johannesburg. The matter is one for the minister of education to decide, however, and it is likely that the University of Pretoria which has taken the lead in urging the establishment of an Afrikaans faculty of medicine, will be able to show that it is financially able to support such a school. In that case there is every probability that a third faculty of medicine will be established before long.

Medal for Services to the Profession

The Medical Association of South Africa (British Medical Association) awards a gold medal for meritorious services rendered to the profession. This distinction has heretofore been granted only twice, the first recipient being the late Dr Darley Hartley, the doyen of medical journalism in this country, and the second Dr A J Orenstein the first president of the association. This year a third award has been made, and the medal has been awarded to Dr William Thomas Frederick Davies, one of the best known and most respected medical men in the country. Dr Davies, who obtained his medical education at the school of the London Hospital, graduated M D London in 1887 and three years later came to South Africa where he soon became known as one of the leading surgeons in Johannesburg. He was a soldier as well and commanded the Second Imperial Light Horse in the Southwest campaign in 1915 and was awarded the DSO and CMG. He took an active interest in politics and was for some years a member of parliament, where he did excellent work on select committees and was instrumental in passing the medical dental and pharmaceutical act in 1928. He was for many years chairman of the Transvaal Medical Council and when the four medical councils were united into what is now the South African Medical Council he was unanimously elected president, a position which he still holds. Dr Davies is a man of charming personality, cultured and broad minded who is recognized as one of the leaders of the profession in this country. He retired from active practice of his specialty some years ago when he was appointed consulting surgeon to the Johannesburg General Hospital and now lives on his river farm in Natal.

ITALY

(From Our Regular Correspondent)

Sept 15, 1937

Radiomedical Center Closed

The Italian radiomedical center, which has been working for two years, was recently closed. Drs. Guglielmo Marconi and Guida were president and director, respectively, of the center. Professor Guida presented to several ministers a report of the work done by the center in 1936. The personnel of the center gave medical advice to be used over the radio for ships which navigated without physicians aboard. The consultations were transmitted by a perfectly organized radio service between ships and the medical center. Both the sailors and the patients were greatly benefited by the service, which was one of the best of its kind, especially because of the geographic situation of Italy in the Mediterranean sea. Patients who became ill aboard were given medical attention by the radiomedical service. Detailed symptoms were sent by radio to the medical center, which sent back instructions for treatment and management of the case. When emergency operations were indicated, the ships were ordered to land their patients immediately.

Insurance Against Disease in Sailors

A law concerning health insurance of sailors was recently passed by the cabinet council. The insurance benefits will be as follows: Sailors who are taken ill while on duty will be given complete medical and surgical care with hospital expenses paid as well as a daily allowance equal to 75 per cent of the daily salary, the salary to be allowed for one year. The same benefits will be given to sailors who report ill within twenty-eight days of the last day of duty on the ship. Sailors on ships of less than 50 tons capacity are excluded from the benefits. Women on duty on merchant vessels will be given obstetric care and a daily allowance for four weeks before delivery and for four weeks after. In case of the death of a sailor, the family will be given compensation equal to the salary for one month for funeral expenses.

Laws Concerning Health

The subsecretary of state, in a recent session of the senate, reviewed the health laws. A general code is to be published which will contain all the laws concerning health and the work of physicians in provinces and municipalities. Laws concerning pharmacy have already been approved by the cabinet council and will be put into effect in the near future. Pharmacy is given an important standing in relation to the state as a corporation. It is brought up to the standards of the general code of health matters. Laws concerning specific remedies, biologic products and medical and surgical attendance were passed. Laws for the organization of and the construction of hospitals are being prepared. Hospitals are distinguished in two categories by the work they perform, the equipment they have and the diseases treated in them. The members of the staff and the aptitudes of the personnel are given great attention.

Clinical Teaching

An agreement between the directors of the clinics of Rome University and those of the reunited hospitals was recently signed. There was an old controversy because of the fact that the hospitals have to provide teaching clinical material to the clinics of the university without any benefit to the hospital physicians. The agreement establishes that the heads of clinical wards are to be considered from now on assistants to the clinical professors. They will give instruction to the students under the direction of the clinical professors and have the rights of regular professors but will depend on the hospital for their appointment as heads of wards and on the university for appointment as teaching professors. Students in the last three years

of medicine will be accepted, under the responsibility of the university, in helping hospital physicians in emergencies. The heads of the clinics have authority in selecting the cases for clinical teaching and demonstration to the students.

Practical Hospital Training Now Required

The minister of national education recently promulgated the following regulations. Students of medicine must have an internship of at least six months without interruption. During this time they will have a practical training in clinical medicine, surgery, obstetrics and gynecology. The internship is to be made after having satisfactorily passed the examinations of the sixth year of medical studies. The clinics will be open all through the summer. The professional examinations are presented not later than July 15. As soon as the internship is fulfilled, the young physicians can take the state examination so as to practice.

Personals

Prof. Cesare Colucci, director of the Istituto di Psicologia sperimentale of Naples University, resigned because of the age limit and was appointed professor emeritus. He was also the head of the psychopathic hospital and the first teacher of experimental pathology in Italian universities. He gave testimony as an expert in more than 100 medicolegal cases. He has published about 140 articles, especially reports of experiments and books on anatomy and histology of the nerve cell, the retina and the organs of vision and, in collaboration with Palladino, showed the nervous connections of those structures to the frontal lobe in man. His studies on cataplexy are of importance. The edition of his book with lectures on psychology was completely sold out.

Marriages

- LAURENCE M. WING, Wailuku, Maui, Territory of Hawaii, to Miss Jeanne Pauley of St. Joseph, Mich., in Honolulu, July 22.
 RICHARD HENRY WALKER JR., Mountain Home, Tenn., to Miss Mabel Barbara Callahan of Lynchburg, Va., June 10.
 LEWIS R. SCUDDER, New York, to Miss Dorothy Lucille Bridger of Genoa, Ill., in Sycamore, Ill., in July.
 WILLIAM FIELDING BRYCE, Brooklyn, to Miss Helen Marguerite Thacker of Reidsville, N. C., July 20.
 JOHN MAX McCULLOCH, Knoxville, Tenn., to Miss Mary Elizabeth Bryan of Ralph, N. C., July 2.
 EUGENE N. SMITH, Gainesville, Texas, to Miss Frances Marion Beeson of Fort Worth, June 30.
 COLVIN WOOD SALLEY, Baytown, Texas, to Miss Justina Louise Campbell in Houston, July 3.
 RALPH CHANDLER PARKER JR., Batavia, N. Y., to Miss Marta Aspegren of Norfolk, Va., July 20.
 HARRY B. NEEL, Rochester, Minn., to Miss Maj. Stina Bjornson of Wellsville, N. Y., July 29.
 ARCHIE LIPE BARRINGER to Miss Mary Evans Fowl, both of Mount Pleasant, N. C., in July.
 EMMETT EDWARD MARTIN, Haines City, Fla., to Miss Marion Marston of Tampa, in June.
 JOHN PHILLIP LYNCH to Miss Helen Mansfield Davis both of Richmond, Va., June 25.
 ORVILLE N. NELSON, Bay Pines, Fla., to Miss Jane Sherwood of Kimball, Minn., June 30.
 WILLIAM WALLACE FULLER to Miss Anne Olive Bas, both of Richmond, Va., July 10.
 NEILL HENRY McLEOD JR., to Miss Sara Leinster, both of Raleigh, N. C., June 26.
 CARL WISE MEADOR to Miss Margaret Anna Mitchell, both of Richmond, Va., July 7.
 JOSEPH H. STEGER to Miss Helen Presley, both of Fort Worth, Texas, July 7.
 WILLIAM B. SWIFT, Fort Worth, Texas, to Miss D. Rowland, July 12.
 FRANK B. DUNCAN to Miss Estelle Brum, both of Fort Worth, Texas, July 3.

Deaths

Henry Robert Murray Landis ☉ Philadelphia, Jefferson Medical College of Philadelphia, 1897, since its inception on the staff of the Henry Phipps Institute and for many years director of the clinical and sociological departments, professor of clinical medicine at the University of Pennsylvania School of Medicine, formerly demonstrator of clinical medicine at his alma mater, one of the founders and an honorary vice president of the National Tuberculosis Association president of the Pennsylvania State Tuberculosis Society, 1928-1931, member of the board of directors of the Philadelphia Health Council and Tuberculosis Committee, member of the Association of American Physicians, fellow of the American College of Physicians, for thirty years visiting physician to the White Haven (Pa.) Sanatorium, on the editorial staff of the *American Review of Tuberculosis* co author, with Dr George W Norris, of five editions of a textbook entitled 'Physical Diagnosis and Diseases of the Chest', aged 65, died, September 14, in the Bryn Mawr (Pa.) Hospital

Isaac Ivan Lemann ☉ New Orleans, Tulane University of Louisiana Medical Department, New Orleans, 1900, vice chairman of the Section on Practice of Medicine of the American Medical Association, 1932-1933, since 1914 professor of clinical medicine at his alma mater, assistant professor of medicine, 1910-1914, and instructor in medicine, 1906-1910, member of the Association of American Physicians and the American Clinical and Climatological Association fellow of the American College of Physicians, served during the World War, visiting physician to the Charity Hospital, 1900-1925, and consultant in medicine since 1925, visiting physician to the Touro Infirmary 1907-1919, and chief of the medical service since 1919, aged 60, died, September 2, at Rochester, Minn., of gastric hemorrhage

Leopold Mitchell ☉ Lieut Colonel, U S Army, retired, New Orleans, Tulane University of Louisiana Medical Department, New Orleans, 1910, entered the medical corps of the U S Army as a first lieutenant in 1912, served during the World War, retired as a major in 1922 after eleven years service, according to the acts of June 30 and Sept 14 1922 was advanced on the retired list to the grade of lieutenant colonel by virtue of an act of Congress June 21, 1930, fellow of the American College of Surgeons, visiting gynecologist to the Charity Hospital, member of the adjunct staff of the Touro Infirmary, aged 49, died, September 1, of carcinoma

John Dodds Flagg ☉ Buffalo, McGill University Faculty of Medicine Montreal, Que., Canada 1887, L R C P, Edinburgh, Scotland, and L R C S, Edinburgh, Scotland, 1887, member of the American Academy of Ophthalmology and Otolaryngology, formerly instructor in ophthalmology at the University of Buffalo School of Medicine, on the staff of the Charity Eye, Ear and Throat Hospital of Erie County, aged 77, died, July 19, of carcinoma of the lung

Arthur O Hart ☉ St Johns, Mich, Michigan College of Medicine and Surgery, Detroit, 1894 fellow of the American College of Surgeons, surgeon to the Clinton Memorial Hospital, St Johns, and St Lawrence and Edward W Sparrow hospitals, Lansing, aged 66, died, July 28 in the University Hospital, Ann Arbor, of hypernephroma of the left kidney

Charles Wesley Haywood ☉ Elkhart, Ind New York Homeopathic Medical College and Hospital, 1894, past president of the Elkhart County Medical Society on the staff of the Elkhart General Hospital, aged 67, died, July 14, in the Chippewa County War Memorial Hospital, Sault Ste Marie, Mich, of heart disease

Frederick Dabney Bullock, Larchmont, N Y Johns Hopkins University School of Medicine Baltimore, 1907 assistant professor of cancer research at the Columbia University College of Physicians and Surgeons, New York, on the staff of the Lenox Hill Hospital, aged 58, died, August 15, in Dubois, Pa

Edwin Orren Harrold, Marion Ind, Rush Medical College, Chicago 1902 member of the Indiana State Medical Association past president and secretary of the Grant County Medical Society, on the staff of the Marion General Hospital, aged 61, died July 12, of carcinoma of the prostate

Emory Wallace Richie, Hackensack, N J, Howard University College of Medicine Washington, D C 1916 member of the Medical Society of New Jersey aged 50 on the staff of the Hackensack Hospital where he died July 21 of subarachnoid hemorrhage and acute glomerular nephritis

George Young Davis, Youngstown Ohio Cleveland College of Physicians and Surgeons, Medical Department of the

University of Wooster, 1899 for many years health officer of Mahoning County, and president of the school board of Sebring, aged 70, died, July 9, of coronary occlusion

George Southwick Thompson, Hopkinton, Mass, University of Vermont College of Medicine, Burlington, 1902, for many years school physician, on the staffs of the Milford (Mass.) Hospital and the Framingham (Mass.) Union Hospital, aged 63, died, July 27, of heart block

Frederick Charles Johnson ☉ Bradford, Pa, Cleveland Medical College 1897 Jefferson Medical College of Philadelphia, 1900, fellow of the American College of Surgeons, on the staff of the Bradford Hospital, aged 61, died, July 31, of carcinoma of the bladder

John De Lafayette Grissim, San Francisco, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1893, member of the California Medical Association, fellow of the American College of Surgeons, aged 68 died, July 21

Frank H Thompson, Annapolis, Md, University of Maryland School of Medicine, Baltimore, 1879, for many years a member of the city council, and president of the board of trustees of the local public schools, aged 82, died, July 28, of chronic myocarditis

Alexander A Ross, East Chicago, Ind, Trinity Medical College, Toronto Ont, Canada 1897, member of the Indiana State Medical Association, on the staff of St Catherine's Hospital, aged 68, was found dead in bed, July 19, of coronary occlusion

Frank Crawford Robinson, Walla Walla, Wash, Rush Medical College Chicago, 1902, member of the Washington State Medical Association, fellow of the American College of Surgeons, served during the World War, aged 63, died, July 14

William Edward Reed, Nashua, N H, Harvard University Medical School, Boston, 1901, member of the New Hampshire Medical Society, at one time city physician, county physician and police commissioner, aged 60, died, July 22, in Boston

Roscoe Serrel K Hanigan, Quincy, Mass, University of Maryland School of Medicine, Baltimore, 1916, member of the Massachusetts Medical Society, served during the World War, aged 46, died, July 30, of chronic nephritis and cerebral hemorrhage

Harold Richard Keegan, Chicago, St Louis University School of Medicine, 1925, member of the Illinois State Medical Society, aged 41, was killed July 28, when he fell from a ladder at the Wilgus Sanitarium, Rockford, where he was a patient

Earl Jameson ☉ Walnut Grove, Minn, Hahnemann Medical College and Hospital, Chicago, 1905, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois 1908, aged 60, died, July 19, of meningitis

John Austin Woodmansee ☉ Emporia, Kan, University Medical College of Kansas City, Mo, 1912, aged 52, on the staffs of St Mary's Hospital and the Newman Memorial County Hospital, where he died, July 28, of heart disease

Alexander Stephens Hawkins, Clermont, Fla, College of Physicians and Surgeons, Baltimore, 1879, member of the Florida Medical Association aged 86, died, July 22, in the Umatilla (Fla.) Hospital, of bronchopneumonia

Walter Kendrick Hotchkiss, Brighton Colo, University of Colorado School of Medicine, Denver, 1913, member of the Colorado State Medical Society, served during the World War, aged 48, died July 1, of angina pectoris

Walter Callahan Harris, Worcester, Mass, Tufts College Medical School, Boston, 1918, served during the World War aged 46, died July 10 in St Vincent Hospital, of esophageal hemorrhage and cirrhosis of the liver

Daniel Webster Ward, Tuscaloosa, Ala, Birmingham Medical College 1906 member of the Medical Association of the State of Alabama, served during the World War, aged 56 died, July 29 of coronary occlusion

Corydon Webster Harlow, Melrose Mass Medical School of Maine Portland, 1888 member of the Massachusetts Medical Society on the staff of the Melrose Hospital, aged 72, died, July 7, of coronary thrombosis

Adelbert Merton Hubbell ☉ Haverhill, Mass, Boston University School of Medicine, 1889, for many years a member and at one time chairman of the board of health aged 73 died, July 3 of intestinal obstruction

Frank James Bickford, Centralia, Wash, University of Minnesota College of Medicine and Surgery Minneapolis 1902 served during the World War, aged 66, died, July 22, of a self-inflicted gunshot wound

Milo H Trovillion, Metropolis, Ill., St. Louis College of Physicians and Surgeons, 1892, member of the Illinois State Medical Society, secretary of the Massac County Medical Society, aged 70, died, July 15

Joseph M Hanley, Chillicothe, Ohio, Columbus Medical College, 1877, formerly health commissioner of Chillicothe, aged 81, on the staff of the Chillicothe Hospital, where he died, July 30, of cerebral embolism

Lytleton Thomas Hutto, Newville, Ala., Medical College of Alabama, Mobile, 1903, member of the Medical Association of the State of Alabama, aged 56, died, July 12, in St. Margaret's Hospital, Montgomery

Lydia Etta Smith Farmer, Folsom City, Calif., College of Physicians and Surgeons, Keokuk, Iowa, 1893, member of the California Medical Association, aged 64, died, July 1, in the Sutter Hospital, Sacramento

Frank Piper, Boston, Harvard University Medical School, Boston 1893 served during the World War, for many years medical director of the Boston Mutual Life Insurance Company, aged 71, died, July 8

William Thomas Knowlton, Holden, Mass., Albany (N. Y.) Medical College, 1899, member of the Massachusetts Medical Society, aged 61, died suddenly, July 29, in Athens, N. Y., of coronary sclerosis

David Alexander Hilliard, Geff, Ill., Marion-Sims-Baumont Medical College, St. Louis 1902, member of the Illinois State Medical Society, aged 64, died, July 11, of infection of the gallbladder

Frank Willingham Rogers, Ashburn, Ga., Atlanta College of Physicians and Surgeons 1913, member of the Medical Association of Georgia, aged 49, was killed, July 28, in an automobile accident

William Merrill Plimpton, Glenwood, Iowa, Chicago Homeopathic Medical College, 1896, formerly mayor of Glenwood, and for many years a member of the school board, aged 67, died in July

Walter Andrus Phipps, Quincy, Mass., Harvard University Medical School, Boston, 1878, member of the Massachusetts Medical Society, aged 83, died, July 14, in the Quincy City Hospital

Wilburn H. Graves, Pittsburg, Kan., University Medical College of Kansas City, Mo., 1907, on the staff of the Mount Carmel Hospital, aged 53, died, July 9, of cardiovascular and renal disease

Simeon Kelly, Zanesville, Ohio, Miami Medical College Cincinnati, 1895, member of the Ohio State Medical Association, formerly health officer, aged 69, died, July 22, of cerebral hemorrhage

Louis H. Glosemeyer, O'Fallon, Mo., Beaumont Hospital Medical College St. Louis, 1897, member of the Missouri State Medical Association, aged 65, died, July 19, of coronary thrombosis

Jonas Dabner Hartzell, North Star, Ohio, Medical College of Ohio Cincinnati, 1893, member of the Ohio State Medical Association, aged 66, died suddenly, July 24, of coronary embolism

Fred G. Stone, Sledge, Miss., Chattanooga (Tenn.) Medical College, 1907, member of the Mississippi State Medical Association, aged 56, died, July 18, in Tupelo, of angina pectoris

Fred Hyde Bethune, Emo, Ont., Canada, Trinity Medical College Toronto, 1898, served with the Canadian Army during the World War, aged 66, died July 28, of valvular heart disease

Stephen W. Goodrich, Yonkers, N. Y., New York Homeopathic Medical College 1871, Civil War veteran, aged 90, died, July 27, of contusion of the chest wall and chronic myocarditis

Clarence Elbert Aldenderfer, Mendon, Mich., Barnes Medical College St. Louis 1907, aged 61, died, July 22, in the University of Michigan Hospital, Ann Arbor, of carcinoma

George Dosson Andrews, Walsenburg, Colo., Missouri Medical College, St. Louis, 1893, past president of the Huerfano County Medical Society, aged 76, died, July 20

William Anderson McCauley, Copper Cliff, Ont., Canada, Trinity Medical College Toronto 1902, aged 58, died, July 7, of heart disease while swimming at Lake Penage, Ont.

James Joseph Grady, New York, University of the City of New York Medical Department 1894, aged 67, died, July 12, of pulmonary tuberculosis and chronic nephritis

Benjamin Logan Holmes, Carrollton, Ky., University of Louisville (Ky.) Medical Department 1889, served during the World War, aged 71, died July 3, of heart block.

Ambrose Cecil Stewart, San Diego, Calif., New York Homeopathic Medical College and Hospital, 1887, aged 82, died, July 24, of arteriosclerosis and heart disease

Otto W. Henssler, Chicago, College of Physicians and Surgeons of Chicago, 1893, aged 68, died, July 26, in the American Hospital, of carcinoma of the stomach

Robert Clarence Hull, Detroit, Detroit College of Medicine, 1911, member of the Michigan State Medical Society, aged 49, died, July 14, of heart disease

Frank Miner Kerry, Benton Harbor, Mich., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1887, aged 78, died, July 23, of pneumonia

Timothy Joseph Halloran, Lowell, Mass., Harvard University Medical School, Boston, 1899, aged 63, on the staff of St. Johns Hospital, where he died July 3

Martin S. Gillespie, Edinboro, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1895, aged 70, died July 28, of cerebral hemorrhage

Meyer Katzenberg, New York, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1885, aged 74, died, July 22

Adolph Martin Restenberger, Philadelphia, Temple University School of Medicine, Philadelphia, 1920, aged 47, died, July 11, of carcinoma of the liver

Herman Alvin Wolter, Green Bay, Wis., Rush Medical College Chicago, 1881, aged 81, died, July 25, in St. Vincent's Hospital of prostatic hypertrophy

Harrison H. Doyle, Koppel, Pa., New York Homeopathic Medical College and Hospital, 1891, aged 76, was found dead, July 22, of chronic myocarditis

William O. Patterson, Pueblo, Colo., American Medical College, St. Louis, 1889, member of the Colorado State Medical Society, aged 80, died, July 25

William J. Whiteaker, Dongola, Ill., Barnes Medical College St. Louis 1900, member of the Illinois State Medical Society, aged 65, died, July 17

Daniel Edson Garvin, Golden, Colo., American Medical Missionary College Chicago, 1900, aged 66, died suddenly, July 8, of cerebral hemorrhage

John David Raborn, Trenton, Fla., Mississippi Medical College Meridian, 1909, member of the Florida Medical Association, aged 56, died, July 21

James Edwin Watkins, Lucknow, S. C., Chattanooga (Tenn.) Medical College, 1907, aged 66, died, July 11, in the McLeod Infirmary, Florence

William Baldwin Wayt, Long Island City, N. Y., University of Virginia Department of Medicine, Charlottesville, 1896, aged 67, died, July 17

Andrew Thompson Tallmadge, Keeseville, N. Y., Long Island College Hospital Brooklyn, 1881, aged 78, died, July 3, of cerebral arteriosclerosis

Willis Idol, Leas Springs, Tenn., University of Tennessee Medical Department, Nashville, 1895, aged 73, died suddenly, July 5, of angina pectoris

Margaret Nichols Dassell, Jersey City, N. J., Eclectic Medical College, Cincinnati, 1916, aged 65, died, July 9, of carcinoma of the uterus

Russell Stephen Paterson, Prichard, Ala., University of Toronto Faculty of Medicine, 1919, aged 40, died suddenly, July 14, of heart disease

Eben Aiden, Thomaston, Maine, Long Island College Hospital, Brooklyn, 1878, aged 84, died, July 20, of acute dilatation of the heart

Frederick Dold Georgi, Buffalo, University of Buffalo School of Medicine, 1935, aged 28, died, July 28, of subacute bacterial endocarditis

Archie Edelen Hewitt, Dayton, Ohio, Jefferson Medical College of Philadelphia, 1908, aged 54, died, July 31, of a self-inflicted bullet wound

Cora Belle Brewster, Dover, N. J., College of Physicians and Surgeons, Boston, 1886, aged 77, died, July 25, of chronic myocarditis

Blake E. Gamble, Boiling Springs, Pa. (licensed in Pennsylvania in 1891), aged 67, died July 8, of chronic interstitial nephritis

William R. Mathews, Madison, Ind., Medical College of Indiana, Indianapolis, 1896, aged 63, died, July 27, of heart disease

Louis Green Graves, Atwood, Kan. (licensed in Kansas in 1901), aged 67, died in July of arteriosclerosis

Correspondence

THE USE OF CHEMICALS AS NASAL SPRAYS IN THE PROPHYLAXIS OF POLIOMYELITIS IN MAN

To the Editor.—While I agree with Dr Paul Harmon (Correspondence, *THE JOURNAL*, September 25, p 1061) that the value of nasal sprays of zinc sulfate or other chemicals as a preventive of human poliomyelitis has not yet been established, I cannot subscribe to the views he presents bearing on the pathogenesis of this disease. Dr Harmon cites at length a number of observations supporting his thesis that the causal agent may enter the body through the intestinal tract and summarily dismisses, in one sentence, the results of many years' intensive investigation of the nasopharynx by numerous workers.

On what is the zinc sulfate technic based? The fitting together of many clinical, experimental and epidemiologic observations early led investigators in this field to believe that the nasopharynx constitutes the portal of entry for the virus. Dr Hudson and I (Lennette, E H, and Hudson, N P. Relation of Olfactory Tracts to Intravenous Route of Infection in Experimental Poliomyelitis, *Proc Soc Exper Biol & Med* 32 1444 [June] 1935) demonstrated in 1935 that section of the olfactory tracts in rhesus monkeys prevented infection with virus injected intravenously and suggested that infection by the vascular route may depend to some extent on the amount of virus excreted onto the nasal mucosa, where we had been able to demonstrate its presence. The role of the olfactory tracts was confirmed by Charles Armstrong (*Pub Health Rep* 51 241 [March 6] 1936), who found that picric acid instilled into the nostrils tended to protect monkeys from intravenous inoculations of poliomyelitis virus. In a recent report Schultz and Gebhardt (Zinc Sulfate Prophylaxis in Poliomyelitis, *THE JOURNAL*, June 26, p 2182), who have tried a large series of substances, stated that 1 per cent zinc sulfate sprays proved to be the most efficient in preventing the experimental disease. It is this method which is now being applied to man. The failure of picric acid-alum sprays to protect during the Alabama epidemic (Armstrong Charles. Experience with the Picric Acid-Alum Spray in the Prevention of Poliomyelitis in Alabama, 1936, *Am J Pub Health* 27 103 [Feb] 1937) is admitted, but as an argument against the use of similar sprays it has no weight whatever even the most casual reader of Dr Armstrong's report will perceive that the outcome could hardly have been otherwise. Dr Armstrong's report emphasizes the necessity of an adequately controlled study of zinc sulfate sprays by physicians thoroughly familiar with the technic and appreciative of the fine points involved. Nothing of value will arise from indiscriminate, haphazard spraying of the population.

Dr Harmon's chief objection to nasal sprays, however, apparently lies in his belief that the virus gains access to susceptible tissue by penetration through the intestinal mucosa, in support of this opinion he presents evidence adduced by himself and by Toomey. The presence of virus in the rectal washings of four recent convalescents and its absence in the nasal washings of these and other patients Dr Harmon interprets as evidence that infection occurs by the enteric route. On the other hand attempts by other workers to isolate the virus from stools of human beings and monkeys dying of the disease have been rather uniformly negative even when concentration methods were employed (Clark, P F, Roberts, D J and Preston W S Jr. Passage of Poliomyelitis Virus Through the Intestinal Tract, *J Proc Med* 6 47 [Jan] 1932. Flexner, Simon. Respiratory versus Gastro-Intestinal Infection in Poliomyelitis, *J Exper Med* 63 209 [Feb] 1936). The proponents of the gastro-intestinal theory appear to ignore the obvious possibility that virus isolated from stools may well

represent the causal agent swallowed and concentrated in the bowel over a period of many hours. The virus has also been demonstrated in abdominal sympathetic ganglions, but to assert that it represents virus migrating from the intestine would be to tread dangerous ground, since the virus of poliomyelitis, like those of rabies and Borna disease, possesses the property of wandering long distances along nerve fibers (Flexner, Simon, Clark, P F, and Amoss, H L. A Contribution to the Pathology of Epidemic Poliomyelitis, *J Exper Med* 19 205, 1914).

Unsuccessful efforts to detect the virus in nasal washings have less significance than Dr Harmon would attach to them. The difficulty surrounding implantation of a human virus strain into monkeys, even with the use of spinal cord emulsions, is common knowledge, hence the dilute filtered washings of the nasopharynx could be expected to succeed only rarely. Nevertheless, the virus has been recovered from the upper respiratory tract sufficiently often to be of significance (Kramer, S D, Sobel, A E, Grossman, L H, and Hoskwith, B. Survival of the Virus of Poliomyelitis in the Oral and Nasal Secretion of Convalescents, *J Exper Med* 64 173 [Aug] 1936). As poliocidal antibodies have also been recovered from nasal washings (Amoss H L, and Taylor, E. Neutralization of the Virus of Poliomyelitis by Nasal Washings, *J Exper Med* 25 507 [April] 1917). Dr Harmon's inability to find the virus in the nasopharynx of his convalescents may rest either on its absence, its presence in subinfective amounts or its neutralization by antibody. The simultaneous presence of virus and antibody has been demonstrated in other diseases (Lennette, E H. Studies on the Role of the Spleen in Experimental Poliomyelitis, *J Exper Med* to be published) and has led to the admonition that "caution should be exercised in assuming that any tissue extract or body fluid is necessarily free from virus because it is not infectious" (Topley, W W C, and Wilson, G S. The Principles of Bacteriology and Immunity, ed 2, Baltimore, William Wood & Co, 1936, p 858). From what has already been said it is evident that ability to demonstrate virus in the stool and its apparent absence in the nasopharynx constitute no brief for the gastro-intestinal tract as a portal of entry.

The evidence for the nasopharyngeal portal of entry for the virus of infantile paralysis consists of the recovery of the virus from the nasopharynx of abortive cases, of frankly paralyzed patients and of contacts or healthy carriers (Kramer et al). Other, more indirect, types of evidence are also available, but Dr Harmon believes that these observations lose considerable value because the virus has been found in the nasopharynx of monkeys after its intravenous or intracerebral introduction (Lennette and Hudson. Flexner, Simon, and Amoss, H L. Persistence of the Virus of Poliomyelitis in the Nasopharynx, *J Exper Med* 29 379 [April] 1919) and therefore might be egressing rather than on its way to the central nervous system. The clear-cut results of Dr Hudson and myself as reference to our protocols will show, suggested strongly that infection did not occur in the test animals because virus excreted into the nasopharynx could not reach the central nervous system owing to the break in the olfactory pathway. Furthermore, if the vascularity introduced virus is egressing and not on its way to the central nervous system nasal sprays should have no effect in preventing the disease, Armstrong however, found that they did. Moreover, the occurrence of lesions in the olfactory bulbs of intravenously inoculated monkeys, lesions which occur only when the virus ascends the first and thirteenth cranial nerves (Sabín A B, and Olitsky, P K. The Olfactory Bulbs in Experimental Poliomyelitis. *THE JOURNAL* Jan 2, 1937 p 21. Lennette, E H. Unpublished experiments) strengthens our hypothesis. In this connection it may not be amiss to point out that since these lesions occur at levels where ganglion cells are situated it is imperative to examine minutely complete serial sections of the entire bulb of both sides. As the virus probably multiplies but little during

its ascent up the olfactory nerves, the number of affected mitral cells is small, future pathologic studies should include other parts of the central nervous system, e. g., the anterior perforated substance, which is the site of olfactory neurons of the third order

To the statement that virus in the nasopharynx of cerebrally inoculated, paralyzed monkeys may be on its way out of the body, I have no objection. Recent work by Dr. Gordon and myself indicates that poliomyelitis virus is not absorbed into the blood from either nasal or intestinal mucosa, virus does, however, spill over into the blood during the paralytic stage from its neural site of multiplication, and if the blood-clearing mechanism is not functioning properly, or is overwhelmed, there is no a priori reason why excretion onto the nasal mucosa cannot occur. Proponents of the gastro-intestinal portal of entry might therefore consider the possibility of a similar excretion into the intestine.

A source of astonishment to me was the statement "Monkeys do not contract the disease by the nasopharyngeal route except when heroic [italics mine] methods are used," and the equally terse, unqualified "The disease can be produced in monkeys by the gastro-intestinal tract." What are the "heroic" methods used for nasal inoculation? Simple instillation, with a dropper, of a suspension of infected monkey-cord? I fail to understand how this procedure can be termed heroic when compared with a method involving laparotomy and subsequent injection of the virus subserosally or into a loop of bowel pinched off and ballooned out between clamps.

When simple feeding of virus is considered, the instances of successful infection are conspicuous by their paucity and even this meager evidence possesses equivocal value, since in no case has nasopharyngeal contamination been ruled out. Unless drastic procedures are utilized, normal healthy monkeys are immune to infection by the intestinal route (Lennette, E. H., and Hudson, N. P. Failure to Infect Monkeys with Poliomyelitis Virus Through Isolated Intestinal Loops, *J. Infect. Dis.* 58:10 [Jan-Feb] 1936; Flexner, Clark and his associates).

Dr. Harmon states that Toomey infected by the vascular route monkeys whose olfactory tracts had been sectioned, and that nasal sprays of zinc sulfate did not prevent the disease when virus was administered venously or enterically. Reference to Dr. Toomey's paper (Toomey, J. A. Active and Passive Immunity and Portal of Entry in Poliomyelitis, *THE JOURNAL*, August 7, p. 402) disclosed that he referred to the amounts (not stated) of virus used in his experiments as "proper doses" or "sufficient amounts." What constitutes a "proper" intravenous dose of virus is certainly open to debate. As Hudson and I used without success what are unquestionably large doses, I interpret Dr. Toomey's "proper," in the light of his positive results, as meaning tremendous. When such amounts of an inoculum are injected into the blood stream other factors besides the sectioned olfactory tracts begin to assume a major importance. Overwhelming the blood-clearing mechanism by tremendous amounts of infectious material allows the virus to circulate freely and eventually, even though the olfactory pathway is not available, infection results from penetration of the virus through the blood-central nervous system barrier, a pitfall of which Hudson and I were aware. The same explanation holds for the failure of zinc sulfate to protect against vascular injection of tremendous doses of virus: such experiments merely make use of the blood-central nervous system barrier as a by-pass so to speak.

The use of drastic procedures in gastro-intestinal inoculation also affords the virus an alternative route to the central nervous system. It has been demonstrated (Lennette, E. H., and Hudson, N. P. Blood-CNS Barrier in Experimental Poliomyelitis, *Proc. Soc. Exper. Biol. & Med.* 34:470 [May] 1936) that monkeys whose peripheral nerves are damaged succumb to intravenous inoculation of amounts of virus sublethal for normal animals; absorption of virus from the blood takes place

at the site of trauma. I cannot perceive what possible influence chemicals applied to the nose might be expected to exert in preventing infection by this method. Allowing virus to come into intimate contact with traumatized intestinal mucosa is merely another application of this principle. Since the virus is not absorbed into the blood and hence cannot be excreted into the nasopharynx, the use of zinc sulfate serves only to introduce an unnecessary factor into an experiment the outcome of which is easily predictable. The front door is needlessly nailed shut with zinc sulfate while the back door is invitingly opened by trauma.

The weight of evidence available today is definitely in favor of the nasopharyngeal portal of entry and affords ample justification for a clinical trial of spraying methods. At the same time, if anything of value is to be derived from such studies, they must be done with due regard for technique and be properly controlled.

Research Associate, Department of Bacteriology
and Parasitology, the University of Chicago

THE SUN AND SULFANILAMIDE

To the Editor—I note a number of cases reported in *THE JOURNAL*, September 25, page 1036, in which toxic skin manifestations have occurred with the use of sulfanilamide in which exposure to the sun seems to be a factor.

A white man, aged 25, weighing 160 pounds (73 kg), was seen June 27 suffering from acute gonorrheal urethritis of two days' duration. He was placed on sulfanilamide 20 grains (13 Gm) four times a day for the first day and 15 grains (1 Gm) four times a day thereafter. He was also given by injection a filtrate preparation of the gonococcus. Seven days later he was feeling well except that he complained of some dizziness. That afternoon he sat in the hot Western Kansas sun on the running board of a car for about an hour with his sleeves rolled up, shirt open and hatless. During the night he awakened because he thought he was choking. After coughing a while his choking sensation disappeared and he went back to sleep only to be awakened again a few hours later with a chill. I saw him early that morning at which time his lips and nails were cyanotic, the temperature was 103, and an urticarial type of rash covered his face, neck, hands and arms corresponding to the areas exposed to the sun. There was considerable swelling of the hands, and the face was swollen so much that both eyes were completely closed. Curiously enough he did not feel particularly ill. Sulfanilamide was discontinued and within three days all symptoms, including the urethral discharge, had entirely disappeared.

WENDELL A. GROSJEAN, M.D., Colby, Kan.

CHOLESTEROL AND ATHEROSCLEROSIS

To the Editor—In the clinical lecture on "Disturbance of the Cardiovascular System in Nutritional Deficiency" by Drs. Soma Weiss and Robert W. Wilkins (*THE JOURNAL*, September 4, p. 786) occurs the following sentence: "It has been amply demonstrated that feeding of cholesterol to certain species of animals can induce atherosclerosis or, rather, 'cholesterinsteatosis,' and through it heart disease." Cholesterinsteatosis indeed! The implication, as I take it, is that the condition produced in rabbits by cholesterol feeding is analogous to the lipoidoses, marked by the diffuse permanent storage of fats in the tissues. It is true that in the attempt to produce rapidly atherosclerosis in rabbits there is established a temporary steatosis. When cholesterol feeding is discontinued this condition progressively subsides and there remains a permanent disease of the arteries, a true atherosclerosis, comparable to the natural disease in man. For example, a rabbit had been fed 74 Gm of cholesterol over a period of seven months and had

received none of the lipid for the ensuing two years and one month before its death. At autopsy there was no steatosis. Frozen sections of the liver and spleen, usual depositories of lipid, revealed no anisotropic material under polariscopic examination, and sections stained for fat were negative. Even the adrenals were of less than average size, the cortex relatively poor in anisotropic material. The aorta shows marked dilatation of the arch and upper thoracic portion with widespread calcification, the lesions tallying with those encountered in advanced human atherosclerosis, particularly the senile type. Advanced atherosclerosis of varying degree and without steatosis is found in all rabbits fed an adequate amount of cholesterol and permitted to live following cessation of feeding, as in the case of this animal.

A second sentence in the paper reads "The significance of the cholesterol content of the diet in the causation of human atherosclerosis, on the other hand, is not established." Perhaps the largest human experiment in pathogenesis in medical history was carried out in the period from 1922 to 1930 in the use of high fat diets in diabetes. Cream, butter and eggs, rich in cholesterol, were the common sources of the fats. The production of atherosclerosis on this diet even in children, and the absence of these lesions in the following period under diets poor in cholesterol, furnish to the ordinary understanding at least significant evidence that cholesterol was the cause of the lesions. Finally I have been able to demonstrate in studies of human aortic lesions (Atherosclerosis. Special Consideration of Aortic Lesions, *Arch Path* 21:419 [April] 1936) the apparent etiologic relation of cholesterol to the various stages of the human disease. In a word, atherosclerosis, whether in the experimental animal or in man, has been produced by but one agent, i. e., cholesterol.

TIMOTHY LEARY, M.D., Boston

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

SUBCUTANEOUS ADMINISTRATION OF OXYGEN IN PNEUMONIA

To the Editor—Can you give me information about the subcutaneous use of oxygen in pneumonia? Also technique?

C. M. MEER, M.D., Glendora, Miss.

ANSWER—Oxygen is given in pneumonia to overcome anoxia which may be induced by increased demand for oxygen (due to increased metabolism) or by interference with access of oxygen in the air to venous blood in the alveoli. The latter may be due to closure of the alveoli with exudate or the bronchioles with mucus or froth, which reduces the portal or surface for gas interchange. Sufficient oxygen may be forced into the venous blood through a restricted portal by increasing the gradient between alveolar oxygen and venous blood oxygen and is accomplished by increasing the percentage of oxygen or its partial pressure in the air breathed. When as in pulmonary edema most of the alveolar intruments and bronchioles are filled with froth, the obstructing film may be broken by increasing the actual pressure (to about 10 cm. of water in inspiration) against which the patient breathes. This procedure enlarges the portal for gas exchange and permits better absorption of oxygen and improved escape of carbon dioxide and moisture.

Unless from 300 to 400 cc. of oxygen is absorbed each minute the hemoglobin of the body will not be saturated with oxygen. When unsaturation is as much as 15 per cent in pneumonia the prognosis is distinctly bad. The circulation fails. Failure of the circulation in pneumonia may be due either to lack of oxygen, retention of carbon dioxide or water, bacteremia or exhaustion of essential ingredients in the body. Evans and Durshodwe remark that patients with failing circulation in pneumonia have not been helped by subcutaneous injections of oxygen. If 4000 cc. of oxygen should be injected under the skin of the abdomen, chest and thighs it would take from ten

to twenty-four hours for it to disappear, or, if the absorption should be rapid and uniform, about 6½ cc. per minute (less than 2 per cent of the oxygen required each minute).

Absorption of oxygen depends on a large surface with open capillaries. In the lungs the alveoli provide approximately 80 square meters of such surface. There is a large margin of safety. When oxygen is injected into the tissue planes or subcutaneous tissues the capillaries in the walls of the artefactual alveoli are constricted by pressure, which interferes with absorption of the gas.

The procedure is painful and if its tissues are infiltrated interferes with physical examination of the chest. A vein may be penetrated with gas and air embolism induced.

Recently Evans and Durshodwe have discussed the subcutaneous use of oxygen in pneumonia (*Current Researches in Anesth. & Analg.* 16:211 [June-Aug.] 1937). Those given subcutaneous oxygen simultaneously with or subsequent to oxygen by inhalation were not critically studied with reference to the other factors that make for recovery or death in the pneumonias.

Any painful stimulus such as pricking with a hypodermic needle or subcutaneous injection of an irritating drug, increases the depth of respiration and the activity of the heart and temporarily reduces mild degrees of anoxia. Subcutaneous injection of oxygen offers little promise of assistance in such emergencies as pulmonary edema or obstruction of the bronchus of the lung by secretion. It does not relieve the essential difficulty of gas exchange in pneumonia.

The injection of oxygen may be given directly from a low pressure oxygen cylinder with a 1½ needle 27 gage with a flow meter calibrated in cubic centimeters per minute. A pneumothorax apparatus or 20 cc. syringe with an attached two way stopcock may be employed and the oxygen taken from a glass cylinder immersed in water. The latter method is preferred as being less dangerous and more easy to control if the needle has accidentally perforated a subcutaneous vein.

BULLOUS IMPETIGO OR TOXIC ERYTHEMA

To the Editor—A white woman aged 42 at 10 years of age had a disease which according to her description was pemphigus. Since then she has been unable to perspire on any part of her body except her face. She has a marked sensitivity to soap and water and has to bathe with olive oil. At times her body becomes very hot and radiates an enormous amount of heat especially if she takes a tub bath. At this time she is unable to sleep under bedclothes and has to cool herself by removing the covers and continually turning her pillow. The skin appears normal in every respect and she has been in apparent good health otherwise. What are the possible diagnoses here? Could the pemphigus have been the etiologic factor? What treatment would you suggest?

M.D., California

ANSWER—It is possible, but improbable that the patient had pemphigus. While children may have pemphigus, few survive for thirty-two years. It is more probable that she had a bullous impetigo, an erythema multiforme, dermatitis herpetiformis, a drug eruption or a bullous toxic erythema.

People especially women who do not visibly perspire are not uncommon. This does not mean of course, that they do not perspire at all, for they do produce invisible perspiration. Evaporation of sweat dissipates heat and this is an important method the body uses in ridding itself of excess heat. When the skin cannot sweat the body tends to accumulate and hold for a longer time heat imparted to it, such as from a warm bath.

Sweat contains appreciable quantities of oil and thus helps to lubricate the skin. A dry harsh skin tends to be sensitive to soap and water, because these remove and further reduce the already deficient supplies of oil present.

There are other possible factors that should be searched for. Is there a hypothyroidism to account for the dry skin? What is the patient's basal metabolism? Could these heat episodes be part of the menopause?

The sweat glands are under the control of the vegetative nervous system and lesions of the nervous system have been found post mortem in pemphigus. Is it therefore conceivable though not probable that the deficient sweating is a sequel to a pemphigus?

The more probable diagnoses of the dermatosis present at the age of 10 have been mentioned. Hypothyroidism and the menopause are possibilities at the present time. A functional nervous disturbance is quite possible. If nothing positive can be found in an ordinary physical and laboratory examination of the patient the efforts of a neurologist may be fruitful.

The patient should use little soap and water and continue to use some bland oil or grease such as the olive oil she now is using. Her baths should not be hot but reasonably cool or as cool as comfortable. The clothes should be light and care

should be taken not to become overheated in summer. If hypothyroidism or the menopause are present, appropriate measures should be instituted. It would perhaps be inadvisable to resort to sweat stimulating drugs, such as physostigmine and pilocarpine, for prolonged periods. Certainly their use in this case should be begun and continued with caution.

TREATMENT OF EDENTULOUS PATIENT

To the Editor—A physician aged 55 developed a chronic sinusitis following an attack of influenza. Prolonged treatment included frequent punctures and irrigations of both antrums and sphenoids. There was no pus on irrigation. X-ray examination showed the membrane of the affected sinuses to be hyperplastic the linings being considerably thickened. Owing to an atrophic condition that developed in the mucosa of the nose postnasal space and pharynx he was advised against any operative procedure radical or otherwise being told that the membrane of the sinuses would not regenerate. Roentgenograms taken in December 1935 showed a progressive rarefaction of the bony walls. The nose is dry and there is a thick tenacious discharge both forward and posteriorly which it is extremely hard to dislodge and tends to form crusts. There is considerable fifth nerve neuralgia and for a year or more he has had a generalized multiple neuritis with accompanying muscular weakness and stiffness. Three years ago it became necessary for him to have his teeth removed. His bite is irregular—a forward and cross bite—but prominent dentists assured him that it could be accommodated. Extensive alveolar resection was done by an extractionist. Since then he has had seven sets of dentures but is still unable to eat any but the softest food. What little lower ridge remains is thin and is on the lingual side of the mandible leaving a wide ledge on the labial side. The denture rests on this ledge and on what remains of the ridge. Where the upper ridge should be is scar tissue. The slightest pressure of the plates is extremely painful. With the dentures out the gums cannot be made to touch within an inch. Since the teeth were removed there has been a persistent drawing burning sensation in the mouth and to a lesser degree in the nose. This sensation is greatly aggravated by a mere puff of a cigarette and he has been forced to give up smoking after smoking for many years. The membrane of the mouth is not inflamed but the tongue becomes red after eating or when protruded. The neuritis manifests itself in sudden stabbing and dull boring pains in the extremities and the areas supplied by the fifth nerve. Neurologic examination is negative for spinal involvement. The blood Wassermann reaction is negative. Blood chemistry gives negative results. Red blood cells number 4,390,000 the differential count is normal. Hemoglobin (Dare) is from 76 to 86 per cent. Urinalysis gives negative results excepting for a persistent specific gravity of 1.010. A gastrointestinal series was negative excepting for numerous diverticula in the descending colon and sigmoid flexure. The soft diet necessitated by inability to chew causes constipation with dry pasty stools. A culture from the nose and throat shows *Staphylococcus albus* haemolyticus in heavy growth. *Streptococcus haemolyticus* and *Streptococcus viridans*. At present the patient is taking an autogenous vaccine. 1. Is an atrophic condition a contraindication to operative work on the sinuses? 2. Is autogenous vaccine beneficial in such a case? Over how long a period of time should it be given? What treatment would you suggest for this nasal condition? 3. Is there any soft material that is used in dental plates which will relieve the pain of pressure? Will the tissue over the mandible toughen? What treatment could be used to toughen it? Why does tobacco smoke cause so much irritation? What is the cause of the severe burning drawing sensation and what can be done to relieve it? 4. In view of the mouth and intestinal conditions would the neuritis be due to a vitamin B deficiency? What is the best source of vitamin B orally? Intramuscularly? I will certainly appreciate anything you may be able to suggest that might be beneficial in any of these conditions.

M. D. Washington, D. C.

ANSWER—1. Surgical treatment in the nose and sinuses seems to be contraindicated by both the local and the general conditions. Autogenous vaccines are not likely to have beneficial action. Vitamins A, B and G, both in food and in concentrates with calcium and phosphorus, may be helpful.

2. Dentures are sometimes made for such patients with a velum rubber border or cushion for the base, in some cases, if properly made, they provide relief. A mildly astringent mouth wash may help to toughen and relieve the sensitiveness of the mucous membrane. Tincture of myrrh, 5 cc in half a glass of water, sometimes helps. Burning and drawing sensations are common symptoms of vitamin deficiency. The hypersensitivity of the mucous membrane is the cause of the reaction to tobacco. It will probably disappear as the conditions improve.

The oral surgery was probably injudicious. Some such cases can be improved by deepening the vestibules, both in the maxilla and in the mandible but this can be done only in some cases and should not be attempted by one not experienced in the technique and competent to evaluate the conditions.

Such a climate as Arizona might aid recovery. Damp cold climatic conditions aggravate such cases.

3. Several articles have appeared on diet for edentulous patients. There was a specific article on this subject by Dr. Robert Lejon Ladd which appeared in the December 1934 issue of the *Illness Bulletin* of the University of Illinois College of Dentistry (vol. 18 No. 2). According to this article a diet could be worked out that would meet all the requisites of a normal diet—that is, contain enough calories to keep the normal

body weight, supply an adequate amount of proteins, fats and vitamins, and sufficient bulk to establish a normal bowel movement every day.

UNBREAKABLE LENSES

To the Editor—Several of my patients have inquired regarding unbreakable lenses used in spectacles manufactured by the Unbreakable Lens Company of America Inc. in Beverly Hills, Cal. I have had no personal experience with this product and am therefore hesitant and reluctant to recommend the substitution of this lens for ordinary glass. What information is available on this product?

GEORGE H. LEWIS, M.D., Los Angeles

ANSWER—The Unbreakable Lens Company of America Incorporated, manufactures an unbreakable lens called the Tulca. The lenses are molded from a clear transparent material called plexiglas. The index of refraction of the Tulca lens is 1.4875 on the sodium line D at 30°C. Consequently the strength of the lens must be neutralized with lensometer or with trial lenses. The samples that were supplied on request were of clear transparency, comparing favorably with ordinary glass lenses. The absorption of spectral light (measured roughly) was approximately that of spectacle lenses of similar thickness. Spectroscopically, the absorption was practically identical with ordinary glass lenses. The great difference lies in the weight of the lens, owing to the low specific gravity of plexiglas, Tulca lenses are approximately 60 per cent lighter than glass lenses of the same size and strength. The other advantage is that the Tulca lens does not break or crack even under the application of great force. The advantages of the Tulca lenses are that they scratch easily. When dropped into boiling water Tulca lenses become immediately distorted. They catch fire readily and burn with the same type of flame as does celluloid. The Tulca lens, being a molded structure, cannot be ground or polished although it can be edged and drilled as required.

At present the cost of Tulca lenses is somewhat greater than glass lenses of similar strength. It is believed that the unbreakable lenses are desirable in sports and in cases in which light weight lenses are needed.

X-RAY THERAPY IN WHOOPING COUGH

To the Editor—A daughter whose children have had a bad attack of whooping cough writes that her physician is giving the children x-ray treatments once a week. I did not know that the x-rays were used in this disease until I looked up the subject in the textbooks and even then found little about them and that little seemed to doubt their effectiveness. What is the consensus regarding its use?

W. M. WALLIKER, M.D., Clinton Iowa

ANSWER—Untreated whooping cough is not only a self limited disease, but it varies greatly in duration and severity. The paroxysmal stage ranges from one to ten or more weeks. One can rarely predict whether a child will have a light, medium or severe case. The mild and medium cases far outnumber the severe. Among the factors that seem to influence its course may be mentioned age, previous health, season and intercurrent respiratory tract infections. The clinical course is more likely to be mild in the summer, in robust children (whose specific defense powers are usually well developed) and in a healthful environment. Conversely, many of the severe cases and most of the deaths occur during the first two years of life in rachitic infants of the poor, who are prone to contract complicating bronchopneumonia in winter or enteritis in summer. Furthermore, allergic children of any age, especially those subject to bronchitis, may have severe and frequent paroxysms for many months in spite of therapeutic measures.

In carefully controlled and well conducted clinical observations on pertussis patients, Faber and Struble (Does Roentgen Ray Modify the Course of Whooping Cough? *The Journal*, Sept. 12, 1925, p. 815) showed that x-ray treatment has a therapeutic effect. Sauer and Hambrecht (Whooping Cough: Vaccine Therapy or Early Diagnosis, *ibid.* Dec. 15, 1925, p. 1861) in a carefully controlled series of 100 pertussis patients of various ages and at the various seasons show that pertussis vaccine has no therapeutic effect. Miller and Singer (Roentgen Rays in the Variable Course of Pertussis: Does Haemophilus Pertussis Undenatured Bacterial Antigen Alter It? *Immunology*, March 53, 720 [March] 1937) in a painstakingly controlled study show that undenatured bacterial antigen is of questionable therapeutic value. The use of strong sedatives in infants and frail children is hazardous.

Until the peak of the paroxysmal stage has passed the following precautions are of definite value: bed rest for several days in fresh warm air (outdoors during the entire day in clear weather) easily digestible vitamin rich foods, the avoidance of

drafts, dust and smoke, and prevention of secondary infections. For infants and frail children, a flawless aseptic nursery technic should shorten the clinical course, lighten the paroxysms and markedly decrease pertussis mortality.

CONVULSIONS AFTER LUMBAR PUNCTURE

To the Editor—Kindly supply me with references on the subject of convulsive seizures following lumbar punctures and also inform me whether a direct relationship can be established between a lumbar puncture and convulsive seizures occurring from six to seven hours after the puncture.

M D New York

ANSWER—We have no available references on the subject of convulsive seizures following lumbar puncture. Convulsions following lumbar puncture are exceedingly rare. We have knowledge of convulsions occurring following lumbar puncture in cases of epilepsy and tumor of the brain. As a general rule it would be very difficult to establish any relationship between a lumbar puncture and convulsive seizures occurring from six to seven hours after the puncture unless the patient had some cerebral disease. A convulsion may rarely occur after a lumbar puncture for the induction of spinal anesthesia or following the introduction of a therapeutic agent into the subarachnoid space.

The following references concerning convulsive seizures following lumbar puncture and injection of procaine are available:

TOXIC ERYTHEMA FROM QUININE

To the Editor—A man aged 60 who had a throat infection with symptoms similar to grip was given quinine and forty eight hours later developed erythema and swelling of the skin over the entire body. About five days later the swelling and also a fine desquamation disappeared. The palmar surface of the hands and the soles of the feet peeled in a solid piece. The man says that he has had a similar condition in so called scarlet fever six times previously. I should like an opinion.

KNOW BRITAIN M D Spencerport N Y

ANSWER—Scarlatiniform erythema belongs to the large group of toxic dermatitides and may be caused by sensitization to drugs, foreign proteins or foods, toxins from the intestinal tract, toxins of the infectious fevers, septicæmia, tonsillitis, rheumatism, influenza, abscesses, empyema, peritonitis, chronic infectious foci, gonorrhea and nephritis.

Whether the particular attack was due to quinine a common offender, or to the attack of influenza can be determined by an experimental dose of quinine. The patient should be willing to submit to this test, for if it succeeds he will be able to avoid future attacks.

The onset of the eruption on other parts than the upper part of the chest and neck, its large macular character with sharp limitation and arcs of uninvolved skin, the absence of circumoral pallor, the absence of swelling of the tonsils and fauces, the absence of a heavily coated tongue with red papillae showing through, and the absence of a fine macular eruption on the palate are against scarlatina. Slight fever with moderate increase in pulse rate, no vomiting, no leukocytosis and no blanching about the point of intradermal injection of scarlet fever antitoxin, from 0.1 to 0.2 cc. weigh heavily against scarlatina in favor of the erythema. Early and rapid desquamation and the history of repeated attacks are also valuable evidence in favor of the scarlatiniform erythema.

DIAGNOSIS AND GONORRHEA

To the Editor—A nurse in a hospital in which I am a member of the staff was married about four weeks ago. Two weeks later she developed symptoms of burning and frequency on urination and on investigation gonococci were revealed in smears both from the cervix and from the urethra. Specific organisms were recovered also from the husband following prostatic massage. It was recommended that she be treated for a period of four to six weeks and take leave from her work during that time. She returned after absenting herself for about ten days with letters from two physicians who stated that there were no gonococci in smears. In view of this she wishes to return to work. 1 Assuming that the smears which were first taken were reliably interpreted is it possible that she is now cured? 2 What is the minimum time she should undergo treatment? 3 What is the minimum time she should remain away from attending patients? There seems to be some controversy regarding the handling of this case and a speedy and pointed reply would be earnestly appreciated.

M D New Mexico

ANSWER—1 It may be possible that the patient has been cured after treatment for ten days—anything is possible in medicine. On the other hand, to be cured of a gonococcal infection after ten days is a rarity. The indication to make more smears is perfectly obvious. Smears should be made not only from the cervix and urethra, but also from Skene's glands and Bartholin's glands as well.

2 There is no such thing as minimum or maximum time—the patient should be treated until she is free from gonococci as proved by microscopic examination of the smears from the cervix, the urethra and Skene's and Bartholin's glands. It is best to take these smears one week apart and after three negative smears have been obtained it might be well to make a culture. Furthermore, it might be well in a case of this kind to use provocative measures, such as the use of alcohol and application of 2 per cent silver nitrate to the urethra and then make an examination of the secretion aroused by the silver nitrate.

3 The patient may attend patients provided she has instructions as to the proper management of her infection.

TREATMENT OF SYPHILIS

To the Editor—A woman aged 27 has been under my care for treatment of syphilis since Oct 4 1934. The Wassermann reaction following a seven months stillbirth at that time was plus 4. The patient felt under the impression that she was unaware of her condition and I was unable to determine at that time the length of infection. I instituted treatment as follows (all injections were at weekly intervals): neoarsphenamine 0.6 Gm, a bismuth compound 0.2 Gm. During the courses of bismuth I had her take orally for varying periods potassium iodide 2 grains (0.13 Gm) and red mercuric iodide one twelfth grain (0.005 Gm) three times a day. 1 Neoarsphenamine ten injections Dec 6 1934 Wassermann reaction plus 4. 2 Bismuth compound four injections Jan 10 1935 Wassermann reaction plus 4. 3 Neoarsphenamine eight injections Feb 28 1935 Wassermann reaction plus 4. 4 Bismuth compound six injections April 18 1935 Wassermann reaction plus 4. 5 Neoarsphenamine eight injections June 6 1935 Wassermann reaction plus 4. 6 Bismuth compound eight injections Aug 16 1935 Wassermann reaction plus 4. 7 Neoarsphenamine eight injections Sept 27 1935 Wassermann reaction plus 4. 8 Bismuth compound ten injections Dec 14 1935 Wassermann reaction plus 3. 9 Neoarsphenamine six injections Jan 24 1936 Wassermann reaction plus 4. 10 Bismuth compound twelve injections April 18 1936 Wassermann reaction plus 1. At this stage the patient admitted the probability of infection in 1930 with about six injections in the arm. Spinal fluid examination was done at this time and was negative. A rest period was given until July 11 1936 when the Wassermann reaction was plus 2. 11 Bismuth compound twelve injections Sept 26 1936 Kahn precipitation test strongly positive. Kline precipitation test strongly positive. Kolmer complement fixation strongly positive. 12 Bismuth compound twelve injections Dec 19 1936 Kline precipitation test weakly positive. Kline precipitation test doubtful reaction. Kolmer complement fixation very strongly positive. 13 Bismuth compound twelve injections March 15 1937 Kline precipitation test weakly positive. Kline precipitation test weakly positive. Kolmer complement fixation very strongly positive. During treatment the patient has been otherwise in very good health. Repeated physical and neurologic examinations have been negative. I would appreciate your suggestions as to any future course that I may pursue.

M D Pennsylvania

ANSWER—Apparently from October 1934 to December 1935 the patient has received a total of forty injections of an arsenical and seventy-six injections of a bismuth preparation. It probably would have been better if continued rather than intermittent treatment had been used for the patient at least in the beginning, but since the lumbar puncture is negative and repeated physical and neurologic examinations have been negative, there is not much need for concern provided the cardiovascular apparatus has been examined carefully. It might be well to give the patient a short course of a bismuth preparation twice a year for the next year. There need be no particular concern over the positive serologic reaction. After all one is treating the patient and not the reaction. She has had quite a little

treatment already and seems to be in good condition. Even if the Wassermann reaction does not turn to negative, there is no cause for alarm in this particular case. After the year of further therapy is completed physical examination should be done once a year, along with the general check up that every person should have.

GONORRHEA OR NONSPECIFIC URETHRITIS

To the Editor—A patient states that about two and one-half years ago he was exposed to venereal infection. Twenty-four hours after the exposure he noticed a slight itching at the meatus associated with a mild purulent discharge. This was never profuse and after about ten days treatment with local injections the symptoms disappeared. There was no further treatment. The presence of the gonococcus in the discharge was not determined at that time. About five months ago the patient was married. Sexual indulgence was moderate. Recently there was intercourse when the wife was barely over a period. Two days later the patient noticed a slight burning after voiding and the following morning a drop of pus was seen at the meatus. No further pus appeared until about a week later after the patient engaged in strenuous exercise. Three different smears were apparently negative for intracellular diplococci. The first urine passed showed a few shreds. The second glass was apparently clear. The wife appeared to be free from infection. Is it likely that the infection two and one-half years ago was gonorrhea and that the patient now has a recurrence? If the first attack was a nonspecific infection would recurrences be likely as in gonorrhea? Does a recurrence of any urethral infection indicate that the disease has spread posteriorly and that the prostate is involved? How much value is the complement fixation test in a case of this kind? Is the treatment of urethral infections the same regardless of the causative organism? M.D., New York

ANSWER—Since all the smears were negative, it is unlikely that the infection two and one-half years ago was gonorrhea. The initial symptoms were probably due to nonspecific prostatic infection with secondary urethral discharge. It is well known that prostatitis may remain symptomless for a long period, and it would hence be advisable to examine the prostatic secretion for the presence of pus and bacteria. A localized low grade infection of the urethra is a rare occurrence following intercourse near the menstrual period. The complement fixation test in a case of this kind is of value only when the reaction is positive, a negative reaction is almost certain to be obtained if the test is done by a reliable laboratory. The treatment of urethral infection is not the same for all causative organisms. In most nonspecific infections irrigation with weak, warm solutions of potassium permanganate or oxymercure of mercury are indicated. Oral administration of a good urinary antiseptic may also be employed. If prostatitis is found, massage is indicated, which in itself usually results in improvement of the urethritis.

TOXICITY OF HALOWAX AND CHLORINATED NAPHTHALENES

To the Editor—I should like to have information on the prevention and treatment of acne resulting from working in Halowax. This substance is manufactured by the Halowax Corporation, 247 Park Avenue, New York and is used in treating certain asbestos products in a plant here. Every worker in Halowax has developed the acne in spite of protecting his arms, face, neck, and legs by applications of mercurial cream, sulfur ointments or the commercial substance Protecto before going to work. The skin lesions which begin as papules and gradually become pustular are scattered mostly on the exposed parts, the face and arms. However, quite a few appear also on the trunk and legs. Autogenous vaccines seem to be of no use in treating them. M.D. Pennsylvania

ANSWER—Halowax is the trade name for a series of products that are or contain chlorinated naphthalenes. As long as twenty years ago, skin diseases from chlorinated naphthalenes were described under the name "perna disease" (perchloronaphthalene disease). More recently skin injuries have been described by Fulton and Matthews (The Dermatological and Systemic Effects of Exposure to Hexachloronaphthalene and Chloro-Diphenyl, Special Bulletin 43 March 16 1936 of the Department of Labor and Industry of the Commonwealth of Pennsylvania). This paper presents less extensive data referable to systemic disease. Generally much less is known about the systemic action of various chlorinated naphthalenes in comparison with the dermatoses that they produce. The fumes from these substances induce a general malaise, profound weakness, unstable gait, cardiac weakness, jaundice, toxic nephritis, hematuria, enlargement of the spleen and neuritis including optic neuritis. A brief discussion may be found in the International Labor Office's Occupation and Health volume 2 page 306. In connection with the use of chlorinated naphthalenes for insulation purposes for electrical transmission equipment attention has been attracted to their toxic properties in various Atlantic Coast states including Connecticut and New York. Several fatalities have occurred. The report of an extensive investigation of the toxic properties of vapors from Halowaxes conducted by Drinker and Warren, together with discussions by other authorities, appears in the

Journal of Industrial Hygiene and Toxicology (1936 [vol. 1] 1937). Additional information probably may be procured from the Department of Public Health of the State of Connecticut in Hartford.

MASKS AND ISOLATION IN COLDS

To the Editor—Often it is the duty of nurse, mother or father while having a cold to examine, feed or be near a child that has respiratory infection. Naturally one doesn't want the child to catch a cold. 1. Does wearing a mask (as in an operating room) help? 2. What distance should an unmasked person keep (a) outdoors? (b) in a closed room? 3. Is there any medication that can be sprayed in the air and throat of the infected person that will prevent his giving the cold to the child even though the effects of such a spray are of only short duration? M.D., New York

ANSWER—1. The wearing of a mask may tend to lessen the likelihood of transmitting a cold to a child. This is not to be regarded as positive protection, for a cold may be transmitted even though a mask is worn.

2. (a) Outdoors an unmasked person should keep several yards away. (b) Indoors it is best for an unmasked person to keep entirely away (i.e., out of the room). By using the precautionary measures, the child's safety will be relatively assured.

3. Many medicaments have thus far been tried in an effort to prevent the transmission of a cold, with little or no avail. There is no sure means of preventing the transmission of the cold from an infected person to one not involved, except the complete isolation of the infected one.

ENLARGEMENT OF NECK

To the Editor—A man aged 67, has a peculiar swelling on both sides of his neck. He tells me that the condition began about six months ago. There is no tenderness and no mass. The lateral sides of the neck are simply enlarged. Turning the head causes the enlargement on the opposite side to be more perceptible. The patient is rather heavy and is the picture of health in spite of mild diabetes six or seven years ago. He has consumed quite a bit of liquor in his life. There is no enlargement of the thyroid gland and his heart is normal as is the urine. I could find nothing in the throat that might account for the condition. Please let me know the possibilities in this case. He tells me that he wears a leather collar and formerly wore a 16.

JAMES M. ACKER M.D. Aberdeen, Md.

ANSWER—If one can eliminate the possibility of neoplasms of glandular or lymph nodal masses, the most likely explanation for symmetrical, painless enlargement of the neck is diffuse lipomatosis. The condition has been described as "fetidals" and may be related in some way to Dercum's disease. The deposition of fat may be confined to the cervical region, there may be associated lipoma or diffuse fatty infiltration of other portions of the body. Adiposity of this type not infrequently is noted in middle aged or elderly men and alcohol has been considered an etiologic factor.

Among the other diagnostic possibilities must be considered that of mediastinal tumor or aneurysm, such conditions usually are associated with other signs of intrathoracic pressure and venous engorgement of the face and neck. A roentgenogram of the thorax would eliminate these possibilities. Pulmonary emphysema also may cause some increase in the size of the neck. Occasionally cervical enlargement seems to be related to hypertrophy of the sternomastoid muscle. This apparently is of no clinical significance and is not related to any of the usual types of myopathy.

ELECTRICAL REFRIGERATION

To the Editor—It has come to my attention recently that certain doctors are advising their patients and in particular their diabetic patients that the new electric refrigerators render the food stored in them unsafe and that the regular ice refrigerators should be used. One of the reasons given is dehydration of the food. Will you kindly give an authoritative opinion on this subject?

LEO D. SMITH M.D. Stockton, Cal.

ANSWER—A number of factors enter into the safe refrigeration of foods. Among them may be mentioned the temperature in various parts of the refrigerator, the circulation of air and the humidity. Humidity, it has been claimed, is an essential difference between the ice refrigerator and the mechanical one. The circulation of air and the condensation of water on the coils have a drying tendency in the mechanical refrigerator. All liquids and some other foods, especially cheese and ham, should therefore be covered in the mechanical refrigerator. Controlled conditions of humidity, however, have been considered in the construction of the newest refrigerators. The factors have been discussed in greater detail by Mary C. F. in *Hygiene* (12 626 [July] 1934 and 13 701 [Aug.] 1935).

The Mind of Man. The Story of Man's Conquest of Mental Illness. By Walter Bromberg M.D. Cloth Price \$3.50 Pp 323 with 19 illustrations New York & London Harper & Brothers 1937

This is a fascinating volume on the history of psychotherapeutics. If one remembers that this branch of medicine has been ignored by historians particularly in the United States the significance of the present volume cannot be overlooked. It is the first volume of its kind and it is carefully and interestingly written. The picture of the development of psychiatry from the earliest ages up to the present time is consistently and carefully enumerated. Space is given to the point of view of the ancients, and the development of thoughts about the treatment of mental disorder is carried fairly consistently through the Middle Ages, the witchcraft craze, and the earlier days of liberalizing the treatment of the insane by Pinel and others. The author does not hesitate to include as contributors in this field the works of such people as Mary Baker Eddy, Mesmer and others who have in the past been labeled as quacks but whose position in the development of treatment of mental disease is understood better in the light of a more modern perspective. Hypnotism and suggestive therapy are dealt with to a considerable extent. About a fourth of the book is devoted to the development of the psychoanalytic and allied theories. These are simply discussed with little embellishment and the facts are clear. A number of new techniques such as those of Schilder, Cowles, Wagner-Jauregg and Stackel are mentioned. The most serious criticism that one can lay against this work is that each contributor to the science of mental healing is dealt with in rather a summary fashion and in many cases the whole contributions of such major scholars as Kraepelin and Hoch have been dismissed with only a page or two. This is undoubtedly due to the fact that the author wishes to include almost all the major contributors to psychiatric treatment within the covers of this single none too large volume and at the same time wishes to keep his discussion simple. For this reason perhaps the foregoing criticism cannot be considered too important. All in all, Bromberg gives a simple easily readable

picture of the development of psychiatry from the healing standpoint rather than the diagnostic standpoint, through the ages and up to the present time. It does not, perhaps, give an adequate picture of what psychiatry is doing today in the way of the administration of the mental hospital, child guidance and mental hygiene, but it might at least serve as a stimulant for the reader who wishes to go further into the field. It has an excellent bibliography, and there are a number of pages of plates in the front of the volume dealing with various artists' conceptions of madness and witchcraft. Until a better book is produced, and it may be some time until such a volume appears, although it is said that several extensive, more scientific works are being prepared, the present monograph deserves a place on the shelf of each psychiatrist's library. It would do no harm for general practitioners or even the nonmedically trained who have some interest in the field of treatment of mental disorders to read it. Nobody can go through its pages without realizing what strides psychiatry has made in the treatment of mental disease and without being impressed by the careful and extensive work recorded.

Radlokymographie du cœur et des vaisseaux. Par Emile Bordet et H. Fischgold. Paper Price 30 francs Pp 134 with 66 illustrations. Paris Masson & Cie 1937

This is an excellent summary of the recently developed promising field of roentgenokymography. The development of the technic popularized in particular by Stumpf of Germany is just beginning to be applied in this country. As experience is gained and as the use of this technic is advanced, considerable information should be obtainable concerning the manner of beating of the human heart in health and disease. This technic may lead to an important method of objective diagnosis of heart disorders. For these reasons this monograph is particularly timely and deserves careful attention. The authors are cognizant of the literature, have summarized present knowledge in a clear fashion and have included original observations. They have attempted to correlate the data obtained with the physiology of the heart, and they have made some interesting observations concerning the physiology of the normal human heart which should point the way to future work along these lines. It is regrettable that the enthusiasm of the authors in this connection has permitted them to inject certain a priori conclusions yet to be demonstrated. They properly emphasize that the time curves of the movement of various points on the border of the heart are partly due to (a) general shifts in the position of the heart and to (b) movements in directions other than at right angles to the tangent of the border. Caution must therefore be used in the interpretation of these curves particularly as regards the physiology of the heart. The diagnostic value of the procedure in clinical disorders, however, being arrived at empirically on the basis of experience, is not affected by the manner in which the curves are derived. The publishers have bound some fifty pages of advertisements with the text. This practice should be discouraged. It is unfortunate also that the authors in correlating the roentgenokymographs with other graphic evidence of heart action have utilized records now generally discarded except for historical interest. Nevertheless the cardiologist, the roentgenologist and the internist will find this monograph worth while.

Guiding Your Life with Psychology as a Key. By Josephine A. Jackson M.D. Cloth Price \$2.50 Pp 352 New York & London D. Appleton Century Company Incorporated 1937

Probably every one knows Josephine Jackson's earlier Outwitting Our Nerves' which is rather superficial but seemed to be helpful to a certain number of people. The present volume is devoted particularly to a common sense series of recipes for guidance of self and others with whom one may come in contact. It traces the various problems that may arise from early childhood up to senescence and gives rules as to how they can be controlled. The standards of course are superficial and there is no pretense of deep therapy or any explanation of the mechanisms causing the problem. The atmosphere is not ineducational but is rather that of a motherly woman physician who wants to be as helpful as possible to those who come to her for advice. Most of the information given in the book is sound as far as it goes. Some chapters are actually in question and answer form like the advice to the loveless color is

in the newspapers. The child guidance program is simple and contains various types of advice which are tried and true and which can be applied by almost any mother. Probably the only danger of the volume would lie in the fact that its title might lead a maladjusted person to purchase it in order to straighten out his problems. If it is to be used as a guide for some one who merely wishes a little advisory literature to read but who is basically sound in his emotions, the book should prove to be helpful. It does not, however, and obviously no book can explain to the layman the basic causes of maladjustment and how to overcome them. Since there is no attempt to deal with other than the simplest problems, the book cannot be condemned. It is questionable whether the volume could serve any purpose for the practicing physician unless, perhaps, its chapters on child guidance, marriage guidance and suggestions for a comfortable old age might be referred to the patients who seem to be rather well adjusted but who ask for literature on these subjects.

Die klimatische Behandlung der Tuberkulose und ihre heutige Bedeutung. Von Professor Dr. med. A. Baemeister, Leitender Arzt des Sanatoriums für Lungenkranke in St. Blasien. Sonderdruck aus Brauers Beiträge zur Klinik der Tuberkulose. Band LXXXIX, Heft 3. Paper. Price 1.80 marks. Pp. 28. Berlin: Julius Springer, 1937.

This booklet on climatic therapy in tuberculosis apparently was written for home consumption—in both senses of the word. In places it is difficult to differentiate it from a eulogy on the third reich, as for example these therapeutic gems: 'Fortunately under the influence of the great revolutions in the spiritual, political and economic spheres which we have experienced the repressed and underestimated natural healing factors in the entire field of medicine are again in the foreground. Medical climatology must be scientifically investigated, as it is of greatest importance for racial health, foreign trade and the total national economy. In our German fatherland this has been recognized in authoritative circles. Here in Germany we have climatic health resorts for nearly every disease—which in no way are second to foreign places as to climate or equipment and in many ways surpass them. In this field is a profitable task within the framework of the new four year plan.' Significantly, most of the other resorts mentioned are Italian. If one survives the political economy (perhaps written reluctantly by a man of Baemeister's scientific standing, if not actually under pressure) one finds that effective climatic treatment of tuberculosis involves recognition of the type of disease and the type of the resort. Exudative lesions do well in sedative climates. Fibrotic lesions improve in stimulating climates. Climatic factors include altitude, humidity, wind, temperature, sunlight, electrical charges and barometric pressure. To secure the proper proportions of these elements in the properly selected case, one is referred to lists admittedly compiled with the blatant cooperation of the German Council on Foreign Trade, the National Institute for German Baths, and the German Bath and Climatotherapeutic Association.

Studies in the Psychology of Art. Volume II. Edited by Norman C. Fester. University of Iowa Studies in Psychology No. XIV. Edited by Christian A. Ruckmick. Psychological Monographs Volume XLVIII No. 1. Whole No. 213. Edited by John F. Dashiell and others. Paper. Pp. 113 with illustrations. Princeton & Albany: Psychological Review Company, 1936.

This volume contains eight reports of research done on the psychology of art. The first paper is a study of the art appreciation process at the child level, in which the writer concludes that there are certain techniques necessary to teach the principles of art to children as low as the second, third, fourth and fifth grades. The second paper studies emphatic responses in children and the writer finds that this type of response begins at an early age and may be found even in kindergarten children. Growth is a characteristic of this behavior and it is possible to devise a test which has the ability to discriminate certain relationships as to age and artistic ability. Briefly stated there are four tests to which the child has to give an adjectival response such as pleasantness, unpleasantness or an impression to a certain picture or diagram. The third paper is an extension of a well known art test the McDory down to earlier child levels and the writer demonstrates that the test is valid even as low as grades two and three. Another contribution contained in this volume is the discussion of measurement of

quality in children's paintings, in which a scale is devised that is found to be relatively reliable. A study is made of artistic ability and its relationship to general intelligence, and it was found that artistic ability is related to general intelligence, particularly if there is a higher than average degree of intelligence it is likely to be concurrent with artistic superiority. It was found so another study indicates, that artistic aptitude is not entirely stable, that those who do not have as much esthetic sensitivity as may seem necessary for them may be stimulated so that this sensitivity will increase with favorable physical conditions, such as esthetic surroundings, reasonable motivation and confidence. Norman Meier the editor of the monograph, contributes one study in which he shows that it is possible for a child without instruction to have sufficient inherent artistic ability so that his productions are higher than those which one would expect of those at his age level. Meier thinks that superior intelligence, coupled with fresh and vivid visual perception, acting with a sufficient constitutional inheritance, lies behind innate artistic ability. The last paper describes an instrument for the study of creative, artistic intelligence which is unique and very useful. The whole collection of papers is part of a comprehensive investigation being made at the University of Iowa. Artistic ability is one of the most difficult traits to diagnose and yet one of the most useful to have. Too many people go into artistic work who are not capable, merely because of some extraneous emotional factor. With the increase in knowledge on the matter of artistic ability, which should be sooner or later capably delineated by the Department of Psychology in the University of Iowa, one may find fewer misfits entering the field. Possibly new factors will be detected which can be used to increase the artistic satisfaction of the population as a whole.

Précis de physiothérapie clinique. Par le Docteur Paul Duhamel, chef du service central de physiothérapie de l'Hôtel Dieu. Preface de M. le Professeur Harvier, professeur de thérapeutique à la Faculté de médecine de Paris. Cloth. Price 130 francs. Pp. 603 with 155 illustrations. Paris: Gaulhier Villars, 1937.

The author of this volume is editor of a series of excellent monographs on the principles and technique of the various forms of physical therapy, including radiotherapy. Perhaps this accounts for the present volume being principally devoted to the clinical use of physical measures. The first part presents a concise but somewhat disproportionate description of the five principal procedures in physical therapy: electricity, radiation, water, motion and cold, for of 122 pages only four serve to describe the principles of hydrotherapy including that of cold applications, while the chapter on 'cold' consists of but two pages describing the action and technique of carbon dioxide snow. Four hundred and thirty pages present the clinical application of physical therapy under the chapter headings of disorders of the nervous system, diseases of nutrition, endocrine syndromes, gastro-intestinal, circulatory, respiratory and genito-urinary diseases and disorders of the bones and joints, the blood and hematopoietic organs and the skin. Emphasis is laid throughout on points of differential diagnosis. In his thirty-five years of active experience as head of one of the oldest physical therapeutic departments of Paris the author has paid special attention to nervous disorders and those of nutrition. The last chapter describes the accidents and dangers of electricity. The book is written in a pleasing and easy style and affords a valuable presentation of present day rationale and methods by one of the leading physical therapists of France.

High Blood Pressure. By I. Harlis, M.D. In collaboration with C. A. Aldred, M.D., J. T. Ireland, B.Sc. and C. A. James, M.Sc. A.C. Livermore and Maurice Stern, Research Fellows (From the Liverpool Heart Hospital). Cloth. Price \$3.75. Pp. 132 with 111 illustrations. New York & London: Oxford University Press, 1937.

This small volume is essentially a report of clinical and laboratory researches carried out at the Liverpool Heart Hospital on the problem of the kidney in connection with hypertensive arterial disease. There is no general discussion of the many other aspects of this complex subject. Data from several cases are given in detail and a brief discussion of the results of these studies is followed by conveniently concise conclusions. It is the firm belief of these investigators that a low protein intake reduces the arterial tension largely because of

the lessened necessity for excreting and concentrating large amounts of urea. They state emphatically that "the kidney performs under high protein feeding many times more work than it does under low. Urea is the main factor in this increase." They further conclude that an inability of the kidneys to concentrate the urine adequately is a feature of fully established cases of hypertony, such functional impairment has long been recognized. Nowhere in the book could evidence be found as to the causal relationships of these phenomena, it is just as likely that the hypertensive disease causes the impairment of urea concentration by the kidney as vice versa. The volume should prove of value and interest to investigators and clinical research workers in the fields of hypertensive arterial disease, nephritis and protein metabolism. It presents views quite contrary to the generally accepted opinion in connection with the effects of protein feeding in cardiovascular-renal disease and thus is provocative of thought. It is clearly of little or no interest to the general clinician, for these views must be digested and confirmed before they can be accepted.

Studies on Human Intestinal Protozoa Especially with Regard to Their Demonstrability and the Connexion Between Their Distribution and Hygienic Conditions. By Ruth Svensson. Acta Medica Scandinavica Supplementum IXX. Paper. Pp 115 with 13 illustrations. Stockholm 1935.

This presents an excellent study of survey and diagnostic methods for all the protozoa found in the human intestinal tract. The scope of the study is described in the preface. The author aims "to determine the effectiveness of different examination methods and to find a system of presenting results which would make it possible to compare figures obtained in different surveys." Also she investigated "how certain living conditions among different groups of people influence the spread of intestinal infections in general, using the frequency of intestinal protozoa as an index." No study of pathogenicity or clinical features is attempted. The study is carefully limited to persons showing no evidence of intestinal disorder. This limitation may possibly invalidate the author's general conclusions. An excellent historical and biologic summary covers the entire group of intestinal protozoa. Some may question minor selections of technique, as, for instance, the routine use of magnesium sulfate to obtain loose stool specimens, but all must agree with her dictum that the iron-hematoxylin vital staining method is *par excellence* the best for identification and has the advantage of furnishing permanent preparations. Her judgment that this method is too time consuming for routine use or for large surveys ignores American work demonstrating its practicability in both instances. The author evaluates the merits of (1) examination of formed stools, (2) examination of loose stools and (3) cultivation, and excellently summarizes the advantages and especially the disadvantages of each. Her experience in Sweden confirms studies in the United States showing higher rural incidence and the close relation of protozoal incidence to personal hygiene and to environmental sanitary conditions. She perhaps has not given sufficient attention to American work in this field, in fact, out of 104 references only nineteen have to do with work in the United States. The book will find a necessary place in medical libraries and in the personal libraries of technicians, protozoologists and clinicians interested in this field.

Cancer Memorandum on Provision of Radio Therapeutic Departments in General Hospitals. By A. B. Smallman CBE DSO MD Ministry of Health Reports on Public Health and Medical Subjects No 79. Paper. Price 9d. Pp 32 with 4 illustrations. London His Majesty's Stationery Office 1937.

The purpose of this report is, as the prefatory note by Sir Arthur MacNalty states, the consideration of the present facilities in England for the treatment of cancer and suggestions for adequate care of the cancer patient. The effective treatment of cancer demands cooperation in three highly specialized fields: surgery, radium and x-rays. The conclusion is reached that the radiotherapeutic department should be an integral part of the hospital rather than a specialized annex to it. For adequate treatment in the general hospital all three methods of therapy should be available as well as the necessary diagnostic procedures, including pathologic and x-ray diagnosis and adequate medical service. In small hospitals the provision of full radia-

tion facilities is not feasible economically because they do not run to capacity. For sound economic use of the radio equipment a 300 bed hospital is necessary. For such a hospital about 1 Gm of radium and two tubes for roentgen therapy operating at from 200 to 250 kilovolts, are considered adequate. Valuable appendices to the report include a design for a radiotherapeutic department and one for the conversion of an existing hospital ward into such a department. There is also an appendix giving the recommendations of the British X-ray and Radium Protection Committee and the regulations for the care and custody of radium by the National Radium Commis-

Studies in General Psychology Volume II. Edited by Christian A. Ruckmick. University of Iowa Studies in Psychology No XX. Edited by Christian A. Ruckmick. Psychological Monographs Volume XLVIII No 2. Whole No 214. Edited by John F. Dashiell and others. Paper 76 with illustrations. Princeton & Albany: Psychological Research Company 1936.

This volume is a collection of four short papers by members of the Psychology Department of the University of Iowa. Two of these papers are by D. Ulrich Greenwald. Greenwald studied the psychogalvanic responses, i.e., changes in the skin resistance, in a number of individuals. These psychogalvanic responses are now known as electrodermal responses. Greenwald showed his subjects a moving picture and at the same time studied the emotional reaction to it. From the curve which he obtained he devised a quotient to show the amount of affectivity as measured by his technique. The chief observations of importance were that there was greater variability among females than among males. His second paper deals with the responses of abnormal subjects. These were psychotic patients from the Iowa Psychopathic Hospital and his results here showed that the reaction, according to his method, of the psychotic patients was well within normal limits, that there was greater variation to erotic situations than to dangerous situations, and that there was no distinctive deviation between the various clinical types of mental disease. The third paper is by Mildred H. Rasmus, who uses this technique to see whether there was an exhaustion of affect. She repeated the moving picture and found that the response on the electrodermal test was less the second time. The last paper, by Benjamin Schaefer, is slightly different. Schaefer took records of the electrodermal response, the stimulus being certain movements on the part of each individual. He found that movement responses could be differentiated from emotional responses by differences in the latent period and in the period of deflection. He found that in most individuals there was a lessening of resistance, and he also pointed out that various movements cannot be differentiated from one another by the type of curve. This type of basic research still holds promise as a technique for use in personality and emotional studies. Greenwald's work does not conclusively eliminate the methods used in diagnosis but implies more need for research.

The Essentials of Chemical Physiology for the Use of Students. By I. W. D. Halliburton M.D. J. A. Hewitt Ph.D. D.Sc. Senior Lecturer in Physiology, University of London. Kings College London and W. F. R. Mason Ph.D. D.Sc. Reader in Biochemistry, University of London. Kings College London. Thirteenth edition. Cloth. Price \$1. Pp 330 with 56 illustrations. New York, Toronto and London: Longmans (Green) & Co. 1936.

This edition is the first since the death of Professor Halliburton and embodies certain departures from previous editions. The elementary treatment of organic chemistry has been largely deleted. There has not been as much amplification of the physiologic portion as would be desirable. The treatment of physiologic chemistry, as that term is usually understood is decidedly elementary for a medical student's textbook and the chemistry also sketchy and obviously written for beginning students. This hybrid treatment of physiology and physiologic chemistry has no adequate pedagogic justification at least as far as the American medical school is concerned. There is no real synthesis of chemistry and physiology, any more than is gained simply by binding in one cover texts on each. The lack of critical treatment from a physicochemical point of view is typified in the statement about acid secretion by the gastric glands in which it is suggested that free hydrochloric acid exists in the gastric cells and from there passes by free diffu-

the tenth normal concentration in gastric juice. Both the effect of high acidity in cells on their integrity and the difficulty of accounting for the movement of hydrochloric acid into the secretion escape any comment. It may be that the book serves a useful function for students in Great Britain, where physiological chemistry as a separate teaching branch is less thoroughly established than it is here. But as a textbook for American medical students it is hardly likely to be of great use.

Safeguarding Mental Health. By Raphael C. McCarthy, S.J., Ph.D., President of Marquette University. Cloth. Price \$2.50. Pp. 297. New York: Milwaukee & Chicago: Bruce Publishing Company, 1937.

This book, by the president of Marquette University, is announced as "a key to self mastery and a successful life." The author undertakes to present for lay readers a conception of the nature of mental diseases, their determinants particularly as related to early training, the responsibility of home and of parents in provoking or minimizing adjustment difficulties in children, and the meaning of and need for mental hygiene. The author discusses in some detail parent-child relationships and teacher-pupil relationships. Such chapter headings as those on the danger of defense mechanisms compensating for defeat, the bogey of fear and the fear of oneself indicate the nature of his approach to the problems of adjustment. It is intended to be a popular presentation but it is also superficial and at times not entirely authentic. It is, nevertheless, superior to many popular works in the field, because the author consistently maintains the point of view of good mental hygiene. The superficial nature of the presentation at times betrays the author into oversimplifications that constitute inaccuracies. The chapter on the danger of defense mechanisms, to choose an example, implies that healthy persons do not utilize "defense mechanisms" in a healthy manner. The definition or rather brief discussion of "introverts of whom we hear so much today" (p. 118) constitutes a misconception of the term introvert and of the individuals to whom it might be applied. The discussion under the paragraph on regressive maladjustments (pp. 151-152) again is so excessively simplified as to be misleading. Perhaps it is too much to demand scientific accuracy in as popular a book as this one but the deficiencies noted should be avoidable even in a popular book. One looks eagerly to the chapter on religion and mental health, since the author is in a particularly good position to present this important theme adequately. Here unfortunately he abandons his position as a psychologist and writes as a priest and thereby weakens rather than strengthens his chapter. A much stronger presentation of the mental hygiene value of religion and of religious institutions could be written, and without recourse to such statements as that in the discussion of confession "they are helped by the supernatural aid they receive in fulfilling their office" and the obviously unwarranted statement "the one effective motive that regulates unruly sex impulses is religion." A major defect is the complete omission of advice to parents on the sexual instruction of children. The book is full of sane and wise advice and suggestions which non-neurotic persons will be able to profit by. The point of view it represents warrants its recommendation to mentally healthy general readers, not as a scientifically accurate work on mental hygiene but as a sympathetic discussion of some problems of adjustment.

Anleitung zur Konstitutionsdiagnostik bei kindlicher Tuberkulose (an Hand von praktischen Beispielen). Von Professor Dr. Kurt Kiere, Direktor der Tuberkulose-Kinderklinik, Prinzregent Luitpold, Scheidegg Allee, Heft 17. Pflaum'sche Tuberkulose-Bücherei, Beihefte des Deutschen Tuberkulose-Blattes. Herausgegeben von Prof. Dr. Kurt Kiere. Paper. Price 4.35 marks. Pp. 56 with 22 illustrations. Leipzig: Georg Thieme, 1937.

This monograph contains an introduction devoted to a general discussion of the subject, followed by a detailed description of sixteen cases. The illustrations are mostly reproductions from x-ray films. The author emphasizes the importance of differentiating between nonspecific symptoms among positive tuberculin reacting children with the exudative-lymphatic type of constitution and those which are actually due to tuberculosis. He is of the opinion that a high degree of sensitivity is beneficial to the child and warrants a better prognosis than a low degree of sensitivity. He also emphasizes the fact that children with

only the primary complex do not require institutional care. He does not stress the importance of epidemiologic work or the protection of infected children against reinfection with tubercle bacilli.

Maladie hypertensive et syndromes d'hypertension. Par A. Dumas, professeur agrégé à la Faculté de médecine de Lyon. Paper. Price 22 francs. Pp. 136. Paris: Masson & Cie, 1937.

This is the sixth of a series of small, paper bound monographs. Dumas has written voluminously on circulatory problems, this being the fourth of his monographs on related subjects. He discusses hypertension as a sequel to other disturbances and differentiates hypertensive secondary to renal disorders, uterine and gonadal changes (virilism) and so on. Much more prominent, clear and well written, however, is the discussion of chronic progressive hypertension or hypertensive disease. Here he follows the usual and conventional arrangement, considering in turn the definition of the disease entity, its etiology, symptomatology, complications and accidents, prognosis and treatment. The discussion of therapy is purely conventional and is so brief that it may be called sketchy. Acetylcholine and insulin free pancreatic extract are stressed. The book may be classed as a condensed "brush up" monograph on hypertensive arterial disease which presents the present day French point of view concisely. The bibliography is almost wholly European and largely refers to French literature. Nothing original or thought provoking is found and the book will excite little interest among specialists here. For students and nonspecialists the several excellent American monographs are more than adequate.

The Normal Encephalogram. By Leo M. Davidoff, M.D., Assistant Professor of Neurology in the College of Physicians and Surgeons, Columbia University, and Cornelius D. Dyke, M.D., Assistant Professor of Radiology in the College of Physicians and Surgeons, Columbia University. Cloth. Price \$3.50. Pp. 224 with 140 illustrations. Philadelphia: Lea & Febiger, 1937.

This excellent treatise on lumbar insufflation of air contains essentially the experience of the authors covering 4000 cases and a review of the literature. Their own material includes a description of the technique, indications and contraindications for the performance of the test, and the reaction of the patient during and after the procedure. The illustrations are printed clearly. The authors' technique as well as their descriptive text is simplicity in itself. Davidoff and Dyke follow the simple rule of using encephalography for all patients needing such a test who do not have clinical signs of increased intracranial pressure. This concept is entirely sound. Encephalography should be done by those having experience with the procedure as well as having the ability to interpret properly the films and a thorough knowledge of the anatomy of the brain and the physiology of the cerebrospinal fluid circulation. The bibliography is complete. This brilliant book should be in the hands of all neurologists, neurosurgeons, roentgenologists and physicians interested in air studies of the brain.

Culture des tissus et cancer. Par le Docteur Edward A. Stern de la Faculté de médecine de Paris. Paper. Pp. 136 with 20 illustrations. Paris: Vigot Frères, 1936.

This monograph is not intended to replace the standard textbooks, such as Fischer's, on the methods of the growth of malignant tissue in vitro. It is rather a general analysis of the subject, partly from the author's own investigations and partly from the published work of others. Unfortunately, the author does not explain why a colloidal solution of methylnicholanthrene will produce a high percentage of tumors in mice in the course of two or three months when injected subcutaneously and yet will not change a fibroblast growing in vitro in this suspension into a sarcoma. True des Ligneris claims to have observed this change in fowl tissue, but apparently no one has confirmed this statement and the difficulties of experimenting with a growth like the fowl tumor which is due to some type of virus, renders complete confirmation much more essential than if des Ligneris were working on mammalian tissues. Stern quotes with approval the definition of a cancer cell of which the latest exponent though by no means the originator, is William H. Lewis, that the cancer cell is a diseased cell, that is altered in a permanent fashion so that it is really a new race of cells, and that this change is irreversible in the body and in vitro. Of course this

does not explain anything, it is only a statement of known facts. An excellent bibliography is appended and the volume offers a good survey of the present status of this most difficult and tedious method of biologic experimentation.

Die Praxis der physikalischen Therapie. Ein Lehrbuch für Ärzte und Studierende. Von Dr. A. Laqueur, Professor und Direktor der Abteilung für Physiotherapie im Staatl. Musterkrankenhaus Ankara und Dr. J. Kowarschik, Primararzt und Vorstand des Institutes für Physikalische Therapie im Krankenhaus der Stadt Wien. Fourth edition. Paper. Price 24 marks. Pp. 466 with 234 illustrations. Vienna: Julius Springer, 1937.

This volume is a combination of two earlier textbooks, Laqueur's of the same title, dealing mainly with hydrotherapy and thermotherapy, and Kowarschik's book on electrotherapy. Laqueur, who was for many years head of the physical therapy department at the Municipal Virchow Hospital in Berlin, is now director of that department in the model hospital in the capital of new Turkey. The first half of the volume deals with effects and technics with chapters on hydrotherapy, thermotherapy, balneotherapy (hydriatic applications combined with special chemical and physical stimuli), light therapy and heliotherapy, electrotherapy, massage and mechanotherapy. Special emphasis is placed on the underlying biophysical principles. In the opinion of the authors, short wave diathermy embodies no new principle of treatment and has no specific action. The assertion that short wave therapy would eliminate the necessity for surgery in purulent infections of the skin is not justified. The second half of the volume deals with the physical treatment of various diseases. In both parts the presentation is clear, concise and scholarly. There are numerous excellent diagrams and illustrations. This book represents the most competent and most practical present day German exposition of physical therapy.

Surgery for Dental Students. By Philip H. Mitchell, M.D., M.S., F.R.C.S., Hon. Surgeon to H. M. the King, Clement E. Shattock, M.D., M.S., F.R.C.S., Surgeon and Lecturer in Surgery, Royal Free Hospital, Edward C. Slesinger, O.B.E., M.S., B.Sc., Surgeon and Lecturer in Surgery, Guy's Hospital, and Cecil P. G. Wakeley, D.Sc., F.R.C.S., F.R.S.E., Senior Surgeon and Lecturer in Surgery, King's College Hospital. Cloth. Price \$4.75. Pp. 364 with 105 illustrations. Baltimore: William Wood & Company, 1936.

According to the preface, this book is intended to furnish in the most concise and clear manner the minimum that a dentist is expected to know of surgery and pathology to prepare him for the licentiate examinations in Great Britain. 'To the student it is offered as a textbook containing the knowledge he will be expected by his examiners to possess. Such subjects as general surgical pathology and infections and specific surgical infections, wounds, tumors, cysts, surgical conditions of blood vessels and of nerves, fractures, diseases of bone and of the temporomandibular joint and surgical conditions of the head and neck are discussed in the nineteen chapters. The book contains more pathology than surgery. The treatment is clear and concise, as the preface indicates, and considering the objective, quite satisfactory. From the standpoint of many educators, however, it does not represent what is expected of a dental graduate of the present day.

Veröffentlichungen aus der Konstitutions- und Wehrpathologie. Herausgegeben von L. Aschoff, W. Coelen, W. Koch und P. Schürmann. Geleitet von W. Koch. Heft 39, Band IX, Heft 2: Morgagni's Syndrom. Hyperostosis frontalis interna, Virilismus, Obesitas. Von Folke Henschen, Professor der pathologischen Anatomie am Karolinschen Institut Stockholm. Paper. Price 6 marks. Pp. 82 with 15 illustrations. Jena: Gustav Fischer, 1937.

The author points out that frontal hyperostosis is accompanied by more or less constant symptoms. Adiposity is slow in developing and while finally most pronounced at the shoulders and hips the nuchal region and the abdomen occasionally also become involved. Polyphagia and polydipsia become troublesome manifestations. Muscular asthenia may or may not be the cause of static disorders. The patient also has disturbed sleep, which may culminate in protracted insomnia and states of nocturnal agitation. There are also disorders in urination and often visual disturbances. The syndrome seems to be occasioned by disturbances in the infundibular and tuber cinereal regions, which in a few cases could be verified. The triad of symptoms characteristic of Morgagni's syndrome are (1) frontal

hyperostosis (main symptom), observed in 40 per cent of women during or following the menopause, (2) virilism, including masculine hirsutism and masculine features of the face and (3) adiposity. The syndrome is rarely seen in males. Endocrine disturbances may be the underlying causation and are often associated with senile atrophy of the brain and consequent dyspituitarism. The triad presents similarities to Pierre-Marie's, Cushing's and Frohlich's syndromes.

Funktionsprüfung der Atmung. Von Dr. A. J. Anthony, a. o. Professor, Oberarzt der Medizinischen und Nerven-Klinik Gießen (Prof. Dr. Heinemann). Paper. Price 15 marks. Pp. 226 with 34 illustrations. Leipzig: Johann Ambrosius Barth, 1937.

This is devoted entirely to the function of respiration. A general discussion of the physiology of respiration is presented in twelve pages. Numerous measurements of the thorax such as circumference, volume and diameters, have been studied as well as investigations with the X-rays. Considerable space is devoted to spirometer readings together with the determination of residual air, pneumothorax volume and alveolar air. Throughout the monograph, numerous illustrations are interspersed and detailed descriptions are given of various kinds of apparatus and their uses. The bibliography includes references to the work of many American authors. The volume contains a complete presentation of the subject and should be of value to all workers in this field.

Autonomic Neuro Effector Systems. By Walter B. Cannon, George H. Huggins, Professor of Physiology, Harvard University and Arturo Rosenblueth, Assistant Professor of Physiology, Harvard University. Cloth. Price \$4. Pp. 229 with 42 illustrations. New York: Macmillan Company, 1937.

This monograph is timely in that it expounds in a lucid and interesting style the physiologic evidence and theory bearing on a new field of physiology which has been intensively cultivated during the last decade. This new field pertains to the concept that chemical mediators are concerned in the transmission of impulses from nerves to the muscular and glandular cells they innervate. The organization of functional activity of the autonomic system, as far as the evidence for the chemical mediation of autonomic impulses is concerned, is presented in a simple, concise and well organized manner. The essence of a large mass of literature, difficult for many to read intelligently, has been extracted and is presented so that the busy physician or student may in a few hours become familiar with this new and important subject. This field of physiology is too young to have produced numerous practical applications, yet acetylcholine, the parasympathomimetic mediator, is being used therapeutically. This monograph should be in the library of every physician who desires to keep abreast of his science and to comprehend the references to the chemical mediation of nerve impulses that are now appearing and that will appear more abundantly in the clinical literature.

Zehn Vorlesungen über Kymographie. Von Dr. med. Plehbart, Stumpf, a. o. Professor an der Universität München. Boards. Price \$10.00 mark. Pp. 112 with 80 illustrations. Leipzig: Georg Thieme, 1937.

This volume is a summary with supplementary material, of the author's "Roentgenkymographische Bewegungslehre innerer Organe" published in 1936 by Georg Thieme. Various points criticized in the earlier volume have been clarified and certain additional facts included with particular reference to aiding in the practical use of the methods discussed. The present volume is however chiefly a brief outline and introduction to the earlier work, so the amount of new material is not as great as might have been hoped for, and what is presented is not given much prominence. There is a short chapter on the general principles involved in the technic of the method, together with photographs of the apparatus. There follow nine chapters devoted to the technic and practical uses of the method for the study of the heart, respiratory movements, diseases of the thoracic cavity, movements of the stomach, duodenum and their contents, and the urinary tract. While this is not objectionable in general since the book is admittedly only an outline of an extensive book, the present volume would be much more valuable if the chapters on technic were more complete. An index enables the reader to study the many illustrations and check the author's diagnosis. Unfortunately, the book lacks an index.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice Sponge Left in Abdomen—The plaintiff, as administrator of the estate of Rose Carauddo, sued the defendant, a physician, for malpractice. He alleged that the physician removed the deceased's gallbladder and left in her abdomen a gauze sponge, that four months thereafter another physician removed the sponge and that the patient died from peritoneal infection the day after the second operation. From a judgment in favor of the physician the administrator appealed to the district court of appeals, first district, division 2, California which affirmed the judgment *41 Cal 2d 47 P (2d) 771*, THE JOURNAL Feb 1, 1936, p 411, 54 P (2d) 782. An appeal was then taken to the Supreme Court of California.

The evidence tended to show that neither the defendant the anesthetist, nor an intern who assisted in the operation kept any account of the number of sponges used. No safety appliances, such as metal rings or hemostats were attached to the sponges to minimize the possibility of loss. The defendant contended that it was proper practice for a surgeon to rely on the sponge count of the nurses working under him. But, said the Supreme Court, the reliability of the nurse's count, in order to justify a surgeon in safely acting on it assuming that in some unusual cases he may be justified in doing so, must be determined in each particular case on the basis of the qualifications and efficiency of the nurse and the care and attention which she has exhibited in the performance of her duties. If a surgeon elects to close up an abdominal incision relying solely on the count of the nurse, he must show that he was justified in doing so in the light of all the circumstances attending the operation. While the defendant testified that some one announced that the sponge count was correct there was no evidence that any one counted the sponges. The supervising nurse was present during only a part of the operation. The other nurse was attending an operation for the first time. Neither counted the number of sponges that was brought into the operating room the number that was used, or the sponges left unused after the operation. Proof of the closing of the incision with a sponge left in the abdomen called for an explanation by the defendant in the absence of which an inference arises that the defendant was negligent. The trial court in the opinion of the Supreme Court, should have instructed the jury in unqualified language that if the defendant closed the incision without first having removed the sponge a prima facie case was thereby made against him as a matter of law and that it devolved on him to rebut the inference of negligence by showing that he exercised the degree of care required of him in the circumstances of the case. The care required must be commensurate in all cases with the difficulties and inherent hazards attending the doing of the particular thing undertaken as it is ordinarily performed by other physicians in the same locality in like cases. The skill required to be exercised is presumed to be care of a high degree if the particular case in reason and practice, requires it.

The fact that the hospital did not furnish standard attachments or safety appliances for the sponges does not relieve the defendant from liability. The evidence showed that two other hospitals in the locality did use such safety appliances and the negligent practice of one hospital may not be accepted as a standard for the locality in which it is located. Furthermore there was no emergency in the instant case and the surgeon might have refused to operate until such time as the necessary apparatus had been obtained. He accepted the assignment to operate some time in advance and he knew every fact which might increase the hazards before undertaking the operation. This being so, the defendant assumed the risk of unwittingly overlooking sponges, which risk would in all probability have been eliminated if approved and reasonable precautions had been taken. The physician claimed that to have made a manual search on the completion of the operation for sponges that may

have been left in the operation wound would have subjected him to adverse criticism because such a procedure would be apt to spread the infection. It is difficult to understand the court said, how the possibility of spreading infection could outweigh the necessity of making certain that all foreign substances had been removed from the abdomen when error on the part of the operating physician would result in certain and inevitable injury to the patient. There was no evidence that the patient during the operation was failing or that the exploration was not made on any ground other than a mere possibility, matched against a certainty as to results.

The judgment in favor of the defendant was reversed and the case remanded to the trial court for a new trial—*41 Cal 2d 47 P (2d) 771*.

Workmen's Compensation Acts Court May Not Order Employee to Submit to an Operation—The United States circuit court of appeals, fifth circuit, in a case arising under the workmen's compensation act of Texas, held that the United States district court for the western district of Texas did not have jurisdiction to require the claimant to submit to an operation to relieve a displaced semilunar cartilage. The workmen's compensation act authorizes the industrial board, not the courts, to enter such an order—*Heard v Texas Compensation Ins Co 87 F (2d) 30*.

Radio Electrical Transcriptions Produced in United States for Use on Foreign Broadcasts—Norman Baker and others were indicted April 20 1936, for violations of the Communications Act of 1934. The indictment charged that the defendants located, maintained and used "apparatus from which and whereby sound waves are and were converted into mechanical and physical reproductions of sound waves," and carried transported and delivered and caused to be transmitted and delivered such records or transcriptions to a radio broadcast station in a foreign country, to wit, Station XENT at Nuevo Laredo, Republic of Mexico, for the purpose of being broadcast from that station, which station had a power output of sufficient intensity and was so located geographically that its emissions could be and were received consistently in the United States, without first obtaining a permit from the Federal Communications Commission therefor, all in violation of the Communications Act of 1934. The defendant Norman Baker demurred to the indictment.

The power of Congress to regulate interstate and foreign commerce, including communications by wire and radio, need not be discussed, said the United States district court, S D Texas, Laredo division. Nor is it material whether such communication be wholly by wire or wholly by radio, or in part by both, or in part by some other means or method so long as it is in fact in interstate or foreign commerce. Baker contended, however, that the production of a record or transcription for transmission or delivery, and its transmission or delivery, was not a part of nor a step in either interstate or foreign commerce. With this contention, the court disagreed. The production of a record or transcription, the court said, is but the first step of a sender whose voice and words are recorded thereon, in sending a message in interstate or foreign commerce. The second step is the transmittal or delivery of such record or transcription to a radio station in a foreign country. This may be done by delivering the record or transcription itself to such broadcasting station or by playing the record or transcription and transmitting to such station by telephone or radio, the voice words or message recorded thereon. The third and final step is the radio broadcasting of the voice, words or message back into the United States. If the voice, words or message were transmitted directly by radio or directly by telephone from this country to such radio station in a foreign country the court continued and there broadcast back into this country little or no difficulty would be found in pronouncing it a message sent in interstate or foreign commerce, and within the power of Congress to regulate. Because a phonograph record or an electrical transcription is adopted as one of the steps in sending the message did not in the opinion of the court, change its character.

Believing that the provisions of the Communications Act of 1934 regulating the production of records or transcriptions to

be transmitted to a foreign country and broadcast into the United States were valid, and that the indictment was sufficient, the court overruled Baker's demurrer to the indictment—*United States v. Balcer et al.*, 18 F. Supp. 48

Workmen's Compensation Acts Compensability of Silicosis—Where, as the result of an employer's negligence, an employee breathes quantities of granite dust over a period of time and in the course of his employment and the breathing of such dust causes silicosis, such disease, in the opinion of the Supreme Court of Georgia, is not a result of an injury or accident within the meaning of the Georgia workmen's compensation act and is not compensable thereunder—*Berkeley Granite Corporation v. Cowington (Ga.)*, 190 S. E. 8

Malpractice Duty to Disclose to Patient Unfortunate Results of Treatment—If a dentist fractures the jaw of a patient, said the supreme court of New York, appellate division, the law imposes on him a duty to disclose that fact to the patient so that he, the patient, may obtain treatment for the fracture—*Schocubbaum v. Alper (N. Y.)*, 293 N. Y. S. 817

Vitamin C in Rheumatic Fever and Rheumatoid Arthritis

DR. JAMES F. RINEHART, L. D. GREENBERG, PH.D.,
DR. FRANCES BAKER and F. CHOY, A.B., San Francisco

1 Rheumatic Fever—This study is based on determination of the fasting blood plasma levels of cevitamic acid in rheumatic fever and in other infections and pathologic states in children. Evidence is presented that the blood plasma level is an accurate index of the tissue saturation relative to vitamin C and that in normal persons it parallels the vitamin C intake. In acute rheumatic fever the cevitamic acid content of the blood plasma is found to be almost uniformly lowered. Although in most instances this state of vitamin C depletion probably resulted from inadequate intake, anorexia, digestive disorder and the intoxication of the disease itself are probably contributory factors. A low plasma vitamin C level in a single case is not evidence of scurvy. The latter results from operation of deficiency over a period of time. All evidence indicates that infection itself may deplete the organic store and increase the requirement for vitamin C. The plasma levels in rheumatic fever are, however, significantly lower than in a group of miscellaneous infections. In many rheumatic children although the disease process is clinically quiescent, low blood plasma levels are found. These data are considered

to add significant support to the concept that vitamin C deficiency may be an important factor in the etiology of rheumatic fever.

2 Rheumatoid Arthritis—This communication is a summary of a rather extensive study of the metabolism of vitamin C in health and disease, with particular reference to rheumatoid and other types of arthritis. It is based on determinations of blood plasma levels of the cevitamic acid. The data indicate that a high percentage of patients with rheumatoid and infectious arthritis show significantly low levels of vitamin C in the blood. An attempt is made to evaluate the degree of deficiency existing in these cases and to determine the basis for the development of this state. Cases of hypertrophic arthritis do not show evidence of such deficiency. Data are presented which indicate that some patients with rheumatoid arthritis have either a fault in absorption or utilization of this important food factor. The observations are considered as evidence strongly supporting the thesis previously presented that vitamin C deficiency may be a significant factor in the etiology of certain cases of rheumatoid and infectious arthritis.

DISCUSSION

DR. M. P. SCHULTZ, Washington, D. C. Since the brilliant observation of Dr. Rinehart and his colleagues that guinea pigs subject to the combined influence of chronic scurvy and infection with group C hemolytic streptococci develop a characteristic form of nonpurulent carditis, such experiments have been repeated by four groups of investigators. The observations of Dr. Rinehart have been confirmed in that cardiac damage of the type he originally described develops in guinea pigs subjected to chronic scurvy plus infection or, as appears to be indicated by recent work, uncomplicated acute scurvy. It should be pointed out, however, that none of these subsequent observers consider that these lesions bear a close resemblance to those of rheumatic fever. Warner, Winterton and Clark in a dietary study found that rheumatic children consume as much or more vitamin C containing foods as do controls. They state, indeed, that on the basis of their study the relationship between rheumatic fever and scurvy suggested by Dr. Rinehart cannot be supported. The experiments of Perry and his co-workers in which the degree of vitamin C saturation in rheumatic fever patients and controls was studied also did not support this hypothesis. Dr. Rinehart has described in part the experiments of this type which were undertaken at the Hospital of the Rockefeller Institute work with which I was associated. Because evidence of C hypovitaminosis was by no means found to be regularly associated with rheumatic fever, because similar degrees of deficiency were found to be present in other disease states, and because treatment with large doses of the vitamin were ineffective we concluded that scurvy was not an important factor in the pathogenesis of rheumatic fever. We considered those experiments in which individuals received 100 mg. of cevitamic acid daily in addition to their habitual diets (which in many instances did not seem to be inadequate) for several months before developing rheumatic fever in severe and typical form were of special significance. These patients received several times the quantity of the vitamin considered sufficient to prevent the development of scurvy, and when their degree of saturation with cevitamic acid was tested after the development of rheumatic fever no severe degree of hypovitaminosis C was found to be present. Investigators in this field are unanimous in the conclusion, so strikingly demonstrated by the extensive work of Dr. Rinehart, that some C hypovitaminosis does occur in patients with rheumatic fever. In the past few years about a dozen studies of C metabolism in various infections have been conducted. The degree of saturation with this vitamin has been investigated by measuring excretion after test dose or by estimating the level of blood cevitamic acid in many infections: tuberculosis, pneumonia, typhoid, furunculosis, etc. Studies of this character have demonstrated a tendency to C hypovitaminosis in all infectious states which have been investigated. Concerning the careful and extensive study which Dr. Rinehart has described only two questions occur. The first is regarding the method of titration used. The determination of reduced cevitamic acid by the method of Farmer—

Abt possesses certain advantages in that it is easily and rapidly performed and requires a minimum of chemical manipulation. The disadvantage lies in the fact that reduced cevitamic acid is readily converted to the reversibly oxidized form, a slight degree of hemolysis in the serum for instance accelerates this change and may be responsible for false low readings. As reported in the *Proceedings of the Society for Experimental Biology and Medicine*, Dr Piojan of Rochester, attempting to use the method as originally described by Farmer and Abt (presumably the unmodified method which Dr Rinehart employed), found it entirely unreliable. Further investigation demonstrated that false low readings were obtained unless the specimens were titrated immediately after the blood was drawn. Dr Piojan emphasized the fact that not longer than thirty minutes should elapse between drawing the blood and titration, if reliable data are to be obtained. In that Farmer and Abt did not mention the necessity of observing this precaution, and in view of the extremely low values which Dr Rinehart reports, the observations of Dr Piojan appear to be pertinent. I wish to inquire, therefore, whether in the experiments just reported all titrations were performed within the recommended time limit. The other question is with regard to medication received by the patients. Daniels and her colleagues have reported from Iowa that the administration of acetylsalicylic acid to febrile children results in increased excretion of vitamin C. These authors suggest that the unusually low figures which Dr Rinehart reports in children may be the result of depletion of C reserves by antecedent medication with acetylsalicylic acid. I am aware that Youmans and his colleagues have since reported that in the afebrile adults this effect of acetylsalicylic acid could not be demonstrated. Since rheumatic fever patients are chiefly febrile children, however, conclusions concerning C metabolism must be regarded with reservation if the subjects studied had received acetylsalicylic acid or salicylates. In view of the difficulty of finding arthritic patients, especially those with rheumatic fever, who have not been treated with these drugs, I wish to inquire whether Dr Rinehart eliminated this complicating factor in the present study. We are grateful to Dr Rinehart and his colleagues for this extensive study of vitamin C metabolism in infection. In the light of all information at present available on this subject, however, it would be unjustifiable to conclude that the disturbances in rheumatic fever are of greater significance than those of similar character observed in other infections.

DR A. ALMON FLETCHER, Toronto, Ont. It is not easy to assess the significance of Dr Rinehart's observations. It is reasonable to propose that behind the development of rheumatic disease there is some chronic nutritional disorder. It is not likely that the answer to this important question is going to be found in the administration of a few tumblerfuls of orange juice or by the analysis of the patient's diet, because chronic nutritional disorders are likely to be to a large extent, irreversible or slowly modified by dietetic treatment. The production, in experimental animals, of lesions comparable to those of rheumatic fever and rheumatoid arthritis by vitamin C deficiency, is suggestive but does not by any means signify that these lesions are identical with those occurring in man. It is difficult to believe that many patients with rheumatoid arthritis are suffering from subclinical scurvy. Occasionally one observes the spongy, bleeding gums referred to by Dr Rinehart, which undergo prompt improvement with the administration of vitamin C. Much more frequently such changes are absent and, at times, patients with rheumatoid arthritis are made worse by the administration of large amounts of fruit. There is much clinical experience to suggest that patients with rheumatoid arthritis are helped by high vitamin diets and at times the liberal administration of vitamin C appears to be of value. Such measures would suggest that if chronic disturbed nutrition contributes to the development of this disease the disturbance is more of a nonspecific character in which vitamin C may at times be one factor.

DR JAMES M. FAULKNER, Boston. I find myself in such close agreement with Dr Schultz's remarks that I have little to add. The question seems to boil down to whether the low blood cevitamic acid values which Dr Rinehart finds in rheu-

matic fever are a cause or an effect. It has been recognized ever since the earliest published observations on scurvy, 350 years ago, that infection is an important predisposing cause of scurvy. Dr Rinehart has just demonstrated that the blood level of cevitamic acid is usually reduced not only in rheumatic fever but in other infectious diseases the etiology of which is well established. I have had the opportunity at the Boston City Hospital of estimating the blood values of cevitamic acid in patients with and without infection. All these patients had been on diets generally considered adequate in vitamin C content. In forty-three individuals without infection the average blood cevitamic acid value was 131 mg per hundred cubic centimeters, while in sixty-six patients suffering from miscellaneous infectious diseases the average value was 0.64 mg per hundred cubic centimeters. Among the patients with infection there were ten with acute rheumatic fever in whom the average value was 0.48 mg per hundred cubic centimeters. I did not regard the slight difference in average value between the rheumatic group and those with miscellaneous infections as significant. I also had the opportunity to study the vitamin C balance in a case of active pulmonary tuberculosis. The patient was maintained on a diet almost completely lacking in vitamin C and given measured amounts of pure cevitamic acid. It was found that it took 300 mg of cevitamic acid daily by mouth to bring the blood level and urinary excretion of this substance to normal values. Similar observations in a case of acute rheumatic fever revealed the same increased requirement, namely 300 mg a day. It seems to me that Dr Rinehart's observations might be explained on the basis of a nonspecific effect of infection on the metabolism of vitamin C analogous to the effect of infection on the metabolism of iron or of vitamin B. If vitamin C undernutrition were an important etiologic factor in rheumatic fever, one would expect to see rheumatic fever occasionally in the presence of clinical scurvy. I have not yet seen this combination.

DR RUSSELL L. CECIL, New York. Dr Rinehart was kind enough to send me some of his sections last winter. I was interested in some of the lesions produced in the guinea-pig. It seemed to me that, while there were some lesions that showed an infiltrative reaction, the infiltration was not as active as seen in typical rheumatic fever. I should think that controls with other vitamins would be important in this connection. The fact that the patient fails to improve when fed on vitamins is disappointing. The question after all is: Is this deficiency in vitamin C the cause or the effect of the disease?

DR JAMES F. RINEHART, San Francisco. Dr Schultz has raised a number of questions that are difficult to answer. The data presented here are not a final answer to the problem but I believe indicate an imperative need for adequately controlled prophylactic and therapeutic studies. The bulk of the evidence available at the present time indicates that the reduced form of cevitamic acid is the significant and physiologic active form of the vitamin. Dr Schultz has cited the excellent work of Warner, Winterton and Clark. This study is particularly painstaking but I do not believe that it is conclusive. A gross estimate of the intake of fruits and vegetables does not give an accurate idea of the vitamin C intake because of the varied content of this factor in different foods. With respect to the reliability of methods used I may say that we have investigated particularly carefully all possible pitfalls in the methods, and the evidence which I cannot go into at this time, indicates that they are entirely reliable. Data pertaining to the possible influence of acetylsalicylic acid on vitamin C excretion is controversial. As far as we know there is no effect of this drug on the blood levels, also many of our patients were not receiving any form of salicylates. I wish to thank Dr Fletcher for his conservative discussion of this paper and to reemphasize what has been said. Indeed the answer to the problem will not be found by giving a few glasses of orange juice to the patients. Dr Faulkner has raised a pertinent question: that is whether the low blood plasma levels of vitamin C are not secondary to the disease. This question perhaps applies particularly to acute rheumatic fever. There is every indication that infection itself serves at least in some degree to deplete the vitamin C reserves. We believe it to be particularly significant

that approximately 75 per cent of the chronic or inactive cases of rheumatic fever show significantly low plasma vitamin C. An inactive disease would hardly deplete vitamin C reserves. There is no reason to believe that the levels recorded do not represent habitual values for these patients. In rheumatoid arthritis, particularly, only occasionally have we seen severe infections preceding the onset of the disease and in the cases in which we have been able to demonstrate focal infections they have not been of a degree that might deplete the vitamin C reserve. Most of the cases in this study were in the outpatient department, ambulatory and except for the arthritic disability, showed no striking manifestations of infection. Low blood vitamin C levels are not only found in rheumatic fever and rheumatoid arthritis but they have been practically consistently found in these diseases. This consistency is significant. The question has been raised again why we do not see rheumatic fever in patients with scurvy. I do not believe that any one has sufficient data to answer this question. Obvious scurvy is a late and severe form of C deficiency. Clinically manifest scurvy is seen practically only in infancy and in adults. It is uncommon to see recognizable scurvy in individuals of the rheumatic fever age group. Is it not possible that this unrecognized scurvy is present in rheumatic fever or rheumatoid arthritis? If a disease resembling rheumatic fever or rheumatoid arthritis can be produced in animals by vitamin C deficiency (with infection for rheumatic fever picture) it is entirely reasonable that this deficiency would produce comparable states in human beings. Dr Cecil has asked why patients fail to improve on increased vitamin C intake. An adequate study of the effect of high intake of vitamin C in these diseases has not yet been made. In some cases the requirement is abnormally high. A high intake of vitamin C, controlled by chemical studies of the blood or urinary excretion, must be maintained over a long period of time and patients must be followed with care for adequate evaluation. Certain of the deformities produced will not be corrected by any method. I wish to express my thanks to those who have discussed these papers. In summary I may say that not only experimental but clinical, epidemiologic and biochemical studies all point to the possible importance of vitamin C deficiency in the etiology of rheumatic fever and rheumatoid arthritis. These data indicate clearly the importance of comprehensive preventive and therapeutic studies. The necessity of adequate control and long periods of observation must be emphasized.

Multiple Agglutinins in Serum of Patients with Chronic Rheumatoid Arthritis

DR CHARLES W. WAINWRIGHT, Baltimore. Nichols and Stansby first showed that the serum of patients with chronic rheumatoid arthritis possessed the ability to agglutinate so called typical strains of hemolytic streptococci isolated from the blood stream and joints of such patients. Later Olmstead and Dawson showed that this property was not confined to "typical strains" but was present for hemolytic streptococci derived from a variety of sources and for certain strains of pneumococci as well. They also were able to diminish markedly or remove entirely the agglutinins for other strains of hemolytic streptococci of the same serologic group by absorption with a given strain of hemolytic streptococcus.

McEwen, Chassis and Alexander obtained cross agglutinations and cross precipitations with hemolytic streptococci of serologic groups other than the group containing those strains pathogenic for man. They concluded that these cross reactions were probably due to the presence of multiple antigens and the capacity of the individual to form multiple antibodies following infection. Dawson and Olmstead obtained similar results but to a much less degree and concluded that such cross reactions were due to common antigenic constituents in the various groups of hemolytic streptococci and that the agglutination reaction obtained with the serum of chronic rheumatoid arthritis was characteristic for strains of human origin.

We have selected the serums of twenty-five patients with chronic rheumatoid arthritis which agglutinated hemolytic streptococci of human origin beyond question and found that they regularly contained agglutinins for a strain of another serologic group seldom if ever producing disease in man. The

reactions were definite in all instances and in many only a little less in extent than for the strains of human origin. Agglutinins were also present for two other strains of the same heterologous group but less constantly and to a less extent. Ten serums from patients having no disease contained no agglutinins for any of the strains of hemolytic streptococci concerned in this study. The arthritic serums were then examined for agglutinins for alpha streptococci, type I pneumococci, type III pneumococci, the bacillus of dysentery (Flexner), *Bacillus proteus* and *Bacillus coli*. Only occasional reactions were obtained and when obtained the agglutination was present only in low titer, with the exception of type III pneumococcus. However, when a freshly isolated strain of the type III pneumococcus was used the reaction was not obtained and reactions of the serums gave the type specific precipitin reaction for the type III pneumococcus.

The arthritic serums were then absorbed with representative strains of the two serologic groups of hemolytic streptococci in question and with type III pneumococci. It was found that absorption with a representative strain of one group of hemolytic streptococci removed the agglutinins present for that strain and either definitely reduced or entirely removed agglutinins for the strains of the same group. However, agglutinins for the strains of the other group of hemolytic streptococci studied were not affected. When the serums were absorbed with type III pneumococci, any agglutinins present for the type III pneumococcus were removed, whereas agglutinins for strains of the two groups of hemolytic streptococci were uninfluenced or diminished in varying degree but were not removed. The results indicate that the presence of multiple agglutinins for hemolytic streptococci in the serums of patients with chronic rheumatoid arthritis is the most probable explanation of the phenomenon.

The Progression of Deformities

DR JOHN P. STUMP, New York. This tabulation of the common deformities demonstrates the complex progress of the formation of deformities. There is a primary distortion followed by additional deformities, which progress by rule and this is called "The Progression of Deformities." Thus is produced, by accumulation, a complex deformity.

The Common Deformities

Spine	Flexion with rotation
Shoulders	Adduction with internal rotation
Elbows	Flexion (30-40 degrees) with pronation
Wrists	Flexion with ulnar deviation
Fingers	Flexion
	(a) Ulnar deviation
	(b) Atypical extension
Hips	Flexion and adduction—precipitating
	(a) Equinus flexion of knee knock knee and flat foot
	(b) Tilting pelvis
	(c) Increased lumbar lordosis
Knees	Flexion
	(a) Precipitating equinus which encourages abduction and external rotation of hip followed by flat foot knock knee and finally tilting of pelvis to shortened side
	(b) Posterior dislocation of tibia
Feet	Equinovalgus
	(a) Midtarsal pronation
	(b) Depressed anterior arch
	(c) Hammer toes
Jaw	Closed

Many deformities are due to chronic arthritis, therefore all physicians treating arthritis meet the problem of deformities. There is a definite manner of progression from single, simple distortions of one joint to complex serious deformities involving multiple joints. If a patient with a simple distortion of one joint is not protected serious deformities of multiple joints will certainly follow. Familiarity with the nature of deformities and their progression will enable physicians to prevent disabling deformities in most of their patients suffering with chronic arthritis. The question of static strain predisposing normal joints to arthritis and the general subject of the prevention of deformities is suggested by this paper and will be considered in future presentations.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1927 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Rickets Resistant to Vitamin D Therapy—In certain rare cases of rickets, in which the condition is frequently designated rachitis tarda or resistant rickets, more vitamin D than the amount ordinarily effective for the prevention and cure of rickets is required. During the last six years Albright and his associates encountered six such cases at the Children's Hospital. One patient, in whom rickets was particularly resistant to vitamin D therapy, who is now 16 years of age, has been observed for fourteen years. From the data submitted, it is clear that the failure of the patient to respond to vitamin D was due to an intrinsic resistance to the effectiveness of this agent. During the period of intravenous administration of crystalline vitamin D there was no doubt as to the absorption of large quantities of vitamin D, and yet no healing of the rickets occurred. The failure to respond to ultraviolet radiation also suggests an intrinsic resistance to the specific agent. On the other hand sufficiently large doses (from 150,000 to 1,500,000 U S P units) of the vitamin by mouth did produce healing. Therefore the intrinsic factor which prevented the usual response to vitamin D could be overcome when large enough amounts were given. This patient's condition, then is an example of a type of rickets of as yet unknown etiology which is not the result of a deficiency of the ordinary order of magnitude of vitamin D or ultraviolet radiation but which is due to an intrinsic resistance to the antirachitic action of vitamin D.

Brain Potentials During Sleep—Blake and Gerard studied the brain potentials of young adults during normal night sleep, afternoon napping, postinsomnia sleep and, in one case, hypnosis. Depth of sleep was independently determined by the duration of a fixed sound required to awaken the subject (response to a question), by movement, respiration and the like and an orthodox sleep depth curve for the night so obtained. Potential patterns correlate with the depth of sleep not only over long time changes but, in most cases rather accurately over

short time swings. Deep sleep is regularly associated with a large regular potential wave at a frequency of from one half to three a second, lighter sleep with feeble irregular potentials or with the ten a second rhythm. The results are interpreted in terms of excitation levels of cerebral neurons and of the play of nerve impulses on them. With low excitation a slow rhythm is manifest, with stronger excitation a faster one, and in transition between these states asynchrony prevents the manifestation of any regular beat.

Hyperthyroidism in Children—In a series of 26,682 cases of thyroid disease which have been seen at the Cleveland Clinic, four cases of exophthalmic goiter occurred in children less than 5 years of age. The Criles believe that as a rule the hyperthyroidism of children is typical exophthalmic goiter in which all the classic signs are present. Enlargement of the thyroid and exophthalmos are quite constantly observed and the diagnosis can usually be made at a glance. It is apparent that exophthalmos is much more common in the hyperthyroidism of children than in that of adults. For this reason, the eyes should be one of the chief concerns in the management of the child with hyperthyroidism. In all four cases reported, exophthalmos was present and in the second case severe exophthalmos developed during the time the child was under treatment. It is extremely important to make accurate measurements of the position of the eyes if conservative management of hyperthyroidism in a child is to be tried. At the first definite indication of the development of progressive exophthalmos, subtotal thyroidectomy should be performed. In mild or early cases when the patient can be kept under close observation, conservative measures can be given a trial safely. If conservative therapy is selected, focal infection should be eliminated, bed rest prescribed and small doses of iodine and bromides given. But there seems to be no reason for prolonged delay of an operation which in all probability will eventually be necessary. If the patient is adequately prepared for operation and if the postoperative course is carefully managed, there is no reason why thyroidectomy should entail any greater risk in children than in adults. The three most common causes of death following operations for hyperthyroidism are pneumonia, cardiac failure and thyroid crisis. In children there is little danger of postoperative pneumonia, the myocardium is not affected as is so frequently the case in elderly patients and auricular fibrillation and cardiac failure are rare complications. No fatalities have occurred in the last forty thyroidectomies which have been performed for hyperthyroidism in children less than 14 years of age.

Incidence of Diverticulosis of Colon—In order to obtain additional information about the frequency of diverticulosis according to age, sex and race and about some of the most frequently associated pathologic processes, Kocour has collected the data from 7,000 necropsies which were performed at the Cook County Hospital between Jan 1, 1929 and Feb 23, 1935. There were 127 cases, or 1.81 per cent of diverticulosis. In

six cases the cause of death could be attributed to one of the complications of diverticulosis. One hundred and twenty of the patients were 41 years of age or more. Of the 120 cases 115 were uncomplicated. After 40 years of age the incidence of diverticula increases gradually in number and after 60 years of age the increase becomes very pronounced. Diverticula may be found throughout the entire colon, usually with increasing frequency from right to left. Fifty-four, or 42.5 per cent, of the total number of cases showed diverticula confined to the sigmoid colon, while in thirty-nine cases diverticula were found in the sigmoid colon and other parts of the large intestine, making a total of ninety-three cases, or 73 per cent, in the sigmoid colon or sigmoid and elsewhere. In twenty-two cases the entire colon was the site of diverticula, and fifty-two, or 41 per cent, of the cases showed diverticula in the descending colon or the descending colon and elsewhere. The diverticula in the other cases were confined to the cecum, the ascending colon, the transverse colon and the rectum or combinations of each other. There was only one case of carcinoma, it was located in the rectum and was associated with rectal diverticula. Of the 7,000 necropsies, 3,350 were of patients more than 40 years of age and of these 501, or 15 per cent, had lesions of the gallbladder. The percentage of lesions of the gallbladder associated with diverticulosis is twice that of the percentage of lesions of the gallbladder in the 3,350 cases. There were 243 cases of peptic ulcer in patients of 41 years of age or more. In the 120 cases of diverticulosis and diverticulitis there were eleven cases of peptic ulcer. Essential hypertension was present in 1,144, of which fifty-two, or 43.33 per cent, of the total number of cases of diverticulosis were associated with diverticulosis. Of the 127 cases, eight showed diverticula in the small intestine, twenty-seven showed polyps elsewhere in the gastrointestinal tract, eighteen showed carcinoma, and one sarcoma situated other than in the region of the diverticula was found.

Tuberculosis Case Finding—Since such a large number of tuberculous cases are first seen by private physicians Douglas and Vaughan believe that the private physician is the most important factor in the search for patients with tuberculosis. In order to bring this about a campaign of education was launched in Detroit, designed to enlist financial support from the community through public funds, to arouse the public to the necessity of seeking careful examination to make certain that they individually do not have tuberculosis and to educate the medical profession in the steps of the campaign. The newspaper, the radio, talks before special groups and house to house visits by nurses were used to enlist the public in the campaign. The physicians were encouraged to undertake the work by material sent them by mail, by postgraduate courses and by visits from the medical coordinator to individual physicians and to small groups of physicians. The keen interest of the physicians is shown by the fact that more than 800 have signed up as cooperating physicians. Certain groups were selected for tuber-

culin testing contacts to known cases, persons whom the physician suspects of having tuberculosis in the course of examination for other conditions and those persons who live in areas in which the mortality from tuberculosis is extremely high. The method of examination used is that of tuberculin testing all children and adults in these three groups and making a roentgenogram of the positive reactors. Old tuberculin is furnished to the physicians in capillary tubes suitable for the Pirquet test. The private physician makes and reads the test and reports the result to the health department. If the test is positive he will then refer the patient to a cooperating roentgenologist for an x-ray examination with an interpretation based on a single flat film of the chest. This the roentgenologist reports to the original physician and also notifies the health department, indicating the result. All doubtful or positive films are reviewed by a special committee of roentgenologists. After the roentgenogram has been interpreted, the original physician sees the patient for the purpose of observing him more closely, acquainting him with the result of the examination and, if any disease is found, advising him as to hospitalization or other suitable care. Payment for this service is made to the physician on a fee basis. In order to encourage persons to go for these examinations, additional nursing personnel has been placed in the field to urge contacts to known cases of tuberculosis to go to their physicians, and in the areas of high mortality house to house visits are made to urge all persons living in such areas to be examined. A careful follow-up system is the responsibility of the nurses whose duty it is to visit periodically all contacts and to encourage them to be reexamined at regular intervals. Up to the present, 302 of the 850 cooperating physicians have turned in reports of 33,367 tests done. Of this number 7,472, or 22.4 per cent, are reported as positive. This percentage covers children and adults. Individual records are kept for each physician reporting so that, when there is an unusually low or high percentage coming in, his record is more carefully studied and if necessary a conference on technic is arranged. With a few exceptions the testing is being well done. Of the positive reactors, roentgenograms were taken of 5,122 and after careful recheck and elimination of inactive and negative cases originally reported as positive and active there were thirty-five patients with the active childhood type of tuberculosis, 163 with the adult pulmonary type and seventeen with other forms of active tuberculosis.

Tuberculosis in Contacts of Children Who React to Tuberculin—Wells analyzes the data, from the standpoint of the preschool and school child, derived from a tuberculosis survey in Kingston, Jamaica, concluded in February 1934. Of a total population of 7,093, 78.3 per cent were tested with tuberculin and 70 per cent received x-ray examinations of the chest. Seventy-two cases of manifest pulmonary tuberculosis, only eighteen of which were previously known were found among those examined. The conditions discussed by him are tuberculosis in household contacts of children who react to tuberculin, tuberculosis in yard contacts of children who react to tuberculin, and an estimate of the total number of individuals it would be necessary to examine in order to discover cases of tuberculosis if certain principles were applied as a case finding procedure. For the purpose of the study, preschool and school children have been chosen as groups of individuals which might serve through their tuberculin reactions as indicators or reflectors of the location of tuberculous infection in the community. Home visits to reach preschool children are not impracticable and might even be desirable, since they would offer an opportunity for valuable educational efforts. Only thirty-two of the seventy-two cases of manifest disease found in the original survey were in household contact with children. The remaining forty cases comprised eight persons living alone and thirty-two who were living with one or more than one adult. None of these forty cases which were discovered because of a house to house survey could have been discovered through an investigation employing children as a starting point. In the survey population employed for the study, 232 per cent of the households contained preschool children. A certain number of persons with manifest tuberculosis may be in household contact with children who give a negative reaction to tuberculin. The search for cases of manifest pulmonary tuberculosis among the household contacts of tuberculin-positive children as determined from an analysis

of the survey data, would have resulted in the finding of twenty-one cases out of a maximal total of twenty-five cases, a percentage of 84. This number would have been only 29.2 per cent of all the cases found in the original survey, and 65.6 per cent of cases in household contact with children. The examinations comprised tuberculin tests and x-ray examinations, the latter being confined to children positive to 0.01 and 1 mg of tuberculin and contacts positive to 0.01 mg of tuberculin. A total of 3,110 tuberculin tests were given, averaging 148 tests for each new case of manifest disease discovered, 2,086 individuals, including children as well as contacts, were tuberculin positive and if these had been given x-ray examinations it would have meant roentgenographing an average of 99.3 individuals for every new case discovered. The analysis also shows that x-ray examination of persons living in yard contact with children who react to tuberculin would have revealed 68 per cent of the manifest cases found during a house to house survey and 75.4 per cent of the cases among persons living in yard contact with children.

Infections of the Hand from Human Bites—During 1935 Maier observed seventeen cases of infection of the hand due to human bites in the Fourth Surgical Service of the Bellevue Hospital. In most instances the injury was sustained in a fist fight and a laceration was produced over one of the knuckles of the hand. Four cases were in nurses who had been bitten by psychopathic patients and three were in police officers who received their injuries while trying to subdue a prisoner. Any local treatment applied to the laceration has no effect on the injured tendon, as the injured portion slides back when the fist is relaxed. The cutaneous injury may be treated effectively by various agents but the injury to the tendon is well concealed and these agents are ineffectual. This accounts for many of the disastrous results encountered in these infections. Any treatment, therefore, to be effective, must take into account the possibility of this retraction of the tendon. The treatment that the author has found most effective in this type of injury is as follows: A thorough debridement of the injured area is performed, with use of an Esmarch bandage. A careful examination of the underlying tendon is made for any evidence of injury or infection. All tissue suggestive of infection is removed. If there is any evidence of extension into the palm, this should be opened widely. Arsphenamine is then applied to the wound which is then packed with either plain or iodoform gauze.

Arsphenamine is applied daily for two or three days. At each dressing, the wound is thoroughly irrigated with hydrogen peroxide. The dressing is kept wet with either a boric acid or a magnesium sulfate solution. If conservative treatment is decided on, the patient should be watched carefully for the first twenty-four hours, for, if infection is going to spread, it will occur within the first twenty-four hours, and that is the time to institute radical treatment.

*Effect of Heat and of Cold on Certain Symptoms of Multiple Sclerosis Note D J Simons, New York—p 385

Granulomatous Encephalomyelitis Due to an Encephalitozoon—The disease described by Wolf and Cowen is one in which the congenital nature of the encephalitis is strongly supported by the clinical and pathologic evidence, and in which the etiologic agent is apparently a parasite found in the affected tissues. After they completed the study of the pathology of such a case and the associated parasite, two incompletely described instances (one by Janku and one by Torres) of the disease were found in the literature. The occurrence of a spontaneous parasitic encephalitis in rabbits and mice is of interest in relation to this new human disease, because of the resemblance of the organisms involved and certain similarities in the pathology. The case reported occurred in an infant, born in New York City of American parents and dying at 4 weeks of age who had widely disseminated inflammatory lesions of the brain and spinal cord, consisting of granulomas, massive areas of infiltration and necrosis chiefly in the ventricular walls, and corresponding focal, meningeal inflammation. Similar lesions were present in the retina and choroid of both eyes. An organism, about 1.5 by 3 microns in size, usually ovoid and having a polar chromatin mass, was present in the lesions. It was most frequent where the process was most severe. There is a striking resemblance between the granulomas in this case and those seen in spontaneous encephalitis of rabbits and mice caused by Encephalitozoon cuniculi. The organism in the present case closely resembles this parasite of rabbit encephalitis and must be nearly related to it. There is evidence that the infection was congenital. It probably existed as a latent infection in the mother, passing to the more susceptible fetus by way of the placenta. It is proposed that the disease be called granulomatous encephalomyelitis due to an Encephalitozoon or encephalitozoon encephalomyelitis, and the organism Encephalitozoon hominis.

Effect of Heat and of Cold in Multiple Sclerosis—Simons inquired into the effects of heat and of cold on the muscle strength, spasticity, numbness and bladder symptoms in twenty-one patients suffering from multiple sclerosis. Heat had a bad effect on the strength of 62 per cent of the patients. Efforts to learn whether the responsible factor is heat or ultraviolet radiation have not been satisfactory. Those patients who have had heat therapy have almost all noted at once marked weakness. Nineteen per cent had not complained of weakness, but became weak under the influence of heat. Of three who had extensive trials of ultraviolet therapy, two noted no effect and one felt worse. Several patients have had treatment with effective forms of vitamin D therapy without noticeable effects on their symptoms. This suggests that it is not the ultraviolet of sunlight but the heat itself which causes the distressing weakness. Fifteen per cent of the patients felt stronger under the influence of heat. Of thirteen patients complaining of spasticity, 24 per cent felt that heat increased their stiffness, but spasticity was not induced by heat in any patient who did not already complain of it. Two patients believed that stiffness was lessened by heat. The remainder of the twenty-one patients were unaffected by heat so far as spasticity was concerned. Hesitancy, urgency or incontinence was present in fifteen of the cases studied. Cold had no effect on the strength of 48 per cent of the series, 38 per cent were improved and 14 per cent were made worse by cold. Spasticity was unaffected by cold in 48 per cent and was made worse in only 24 per cent. The majority of patients noted no change in numbness during cold weather. The sphincters were not affected by cold in 57 per cent, and 29 per cent noted improved sphincter control. In general, cold has no specific deleterious effect on any one symptom.

Symptoms of the Urinary Tract and Diseases of Abdominal Organs—Mertz contends that the principal indications for a urologic examination in the differential diagnosis of abdominal disease are unexplained abdominal pain, digestive symptoms of obscure origin and abdominal tumor. Hematuria and pyuria are cardinal manifestations of disease of the urinary tract, and their presence must never be ignored. Pathologic changes of the urinary tract may be present and be responsible for symptoms referred to areas remote from the kidney, and the urine may still be free of blood and be sterile. Likewise, under similar circumstances the preliminary x-ray examination may be negative. Pain caused by disease of the urinary organs varies in wide limits in its presence and in its location. It may be referred to the anterior part of the abdomen and resemble that caused by a disease of an intraperitoneal viscus. Pain is always emphasized in the rectal of a clinical history and it may be given such prominence by the patient as to confuse the uninformed physician in its interpretation. Chronic digestive

symptoms may be due to chronic disease of the kidney. The differential diagnosis of an abdominal tumorous mass is always difficult. Palpatory observations alone are insufficient. Special methods of examination will frequently be required and the urologist should be consulted.

New Feeding for Premature Infants—Stoesser and Johnson used a preparation consisting of 40.6 per cent of skimmed cow's milk solids, 10.1 per cent of calcium caseinate, 17.5 per cent of olive oil, 31.7 per cent of a preparation of maltose and dextrin and 1 per cent of halibut liver oil in the treatment of eighty premature babies. Fifty-one premature infants were fed a breast milk formula and seventy-one were given an evaporated milk mixture and served as controls. A simple study of the results revealed that the skimmed milk-olive oil formula was easily assimilated by the infants with a birth weight less than 2,000 Gm., and in this respect it equaled the breast milk formula and surpassed the evaporated milk mixture. The larger infants with a birth weight of more than 2,000 Gm. who received the new preparation made a better showing than the other two units of the larger weight group which were fed the breast milk and the evaporated milk. The preparation may prove to be a valuable addition to premature infant feeding and at the same time lend itself to further modification. Further studies are indicated.

Congenital Hypertrophic Pyloric Stenosis—Rowe points out that the first symptom of congenital hypertrophic pyloric stenosis is vomiting, which usually appears about the second week but rarely may be delayed until after the fourth week. Accompanying this is a loss in weight and a decrease in the size of the stool and in the amount of urine. If vomiting persists, is frequently projectile in type and is free from bile and occasionally exceeds the volume of food taken at the last feeding, a search should be made for further evidence of obstruction. Visible gastric hyperperistalsis usually appears a few days after the beginning of the vomiting. The tumor may not always be found in the first days following the initial vomiting. Later it can be palpated at each examination. It is usually located rather deep in the abdomen near the right nipple line slightly above the level of the umbilicus. The condition of the child and the severity of the symptoms determine the immediate treatment. At one extreme is the young infant with vomiting of only a few days, with little loss in weight, slight dehydration and little disturbance in mineral balance. In such cases fluid parenterally, either physiologic solution of sodium chloride or possibly dextrose solution, will so improve the condition that conservative treatment can be safely attempted, or, if surgery is elected, further preoperative preparation is unnecessary. At the other extreme is the unfortunate infant of 3 or 4 months who can be classified as in an advanced stage of marasmus or atrophy. In some of these babies marked dehydration and alkalosis are potent factors in determining the outcome. The procession of events in such cases is so rapid that therapy may

have to be controlled entirely by clinical observation rather than by time consuming laboratory procedures. The first treatment is directed toward the immediate relief of the symptoms of tetany. This is followed by attempts to restore normal bicarbonate and pH contents of the body fluids together with the restoration of the electrolyte balance. Convulsions are treated with inhalations of oxygen and carbon dioxide in the proportions of two to one. Chloral hydrate by rectum is valuable. Calcium chloride is given intravenously, usually in 5 per cent solution, the dose being 0.25 cc per kilogram of body weight. Calcium gluconate may be used at this time or later. Further dilution of the blood and reduction in the bicarbonate concentration may be accomplished indirectly as a result of selective renal activity following the administration of physiologic solution of sodium chloride or Ringer's solution. After the immediate emergency is controlled, a slow response may make transfusions advisable. The measures employed in the nonoperative treatment must first maintain absolute control of the infant's chemical and physical processes. In every case the operation has been a Fredet-Ramstedt submucous pyloroplasty. The technical difficulties are few and in experienced hands easily handled. The surgical mortality would seem to depend on the surgeon's recognition of the differences of technic in infants and adults. The postoperative treatment again depends on the condition of the child. The prognosis in congenital pyloric stenosis, if recognized early, is very good. In babies with pronounced changes in their physical and chemical processes success will depend largely on the preoperative treatment. Surgical procedures cannot be expected to correct irreparable changes in metabolism.

Insulin and Schizophrenia—Lemere treated seventeen cases of dementia praecox chronic in nature with symptoms of more than eighteen months' duration, with insulin shock. There was a complete remission rate of 23 per cent, as compared to the usual expectancy of 10 per cent in untreated cases. In the nine cases of dementia praecox, recent in nature with symptoms of less than eighteen months' duration, treated with insulin shock there was a complete remission rate of 78 per cent as compared with the usual expectancy of 30 per cent in untreated cases. Insulin shock recovery is better in quality and more rapid in accomplishment than spontaneous remission. Best results are obtained in inverse relation to the duration of illness and chronicity of the psychotic episode. The sooner the condition is recognized and treated the better the results.

Temporizing only leads to the development of irreversible personality changes and deterioration. There is no evidence of any harmful sequels, either physical or mental, as the result of the treatment. All the patients gained physically, and usually they put on weight. Injudicious treatment, with the production of many convulsions, might irreversibly affect the substance of the brain through small hemorrhages. Recent experimental work with the electro-encephalograph during insulin shock has convinced the author that the action of insulin is nonspecific. Any agent that produces a convulsant-like action on the cortex would produce the same result. It just happens that insulin is the most convenient drug, since its action may be stopped almost immediately by the administration of sugar. Almost any psychotic case not definitely organic and not definitely in the manic-depressive group is suitable for this treatment, provided the psychosis is of recent onset.

Rate of Recovery of Skin from Effects of Irradiation
—Qumby and MacComb give data that permit the computa-
tion of the approximate cumulative dose of radiation in the
skin at any time during the treatment period. Studies have
also been made of the effect of different fractionations of a
certain dose delivered in a specified period, and of the effect
of varying the intensity of the radiation when a specified total
dose is delivered in a given time. Curves and a table are
presented from which the accumulated dose in the skin can be
calculated for any day during the treatment period. It is shown
that, if sufficient radiation is administered in a specified time
to produce the threshold effect within the experimental limits
investigated, it makes no difference whether it is delivered in
small doses with short intervals or in larger ones with longer
intervals. If the radiation is administered in a given period it
makes no difference within the experimental limits investigated,

whether it is delivered in long treatments of low intensity or
in short ones of low intensity. The saturation method of dose
calculation cannot be justified when a constant daily recovery
factor is assumed. Since the amount of recovery decreases from
day to day, it is necessary to know the correct recovery factor
for every day. A method is outlined for calculating a true
saturation scheme of irradiation.

**Irradiation in Uterine Bleeding Other Than from
Cancer**—From a study of the literature and their 327 cases
in which permanent menopause was attempted over a period
of seventeen years Lafferty and Phillips conclude that irradia-
tion is the method of choice in the treatment of menorrhagia
other than that due to cancer. There are certain contraindica-
tions: large rapidly growing fibroids, those causing pressure
symptoms demanding quick relief, pedunculated tumors, uterine
polyps, tumors that can be removed leaving the uterus intact,
tumors that have undergone cystic degeneration, ovarian cysts,
extreme mental depression and cases in which partial hyster-
ectomy has been done and bleeding continues from uterine
residue. No woman in the child bearing period and having no
tumor should be subjected to irradiation until all other methods
of treatment short of hysterectomy have failed to effect a cure.
There were fourteen patients who were not cured, in eight of
whom there were contraindications to treatment. Of the 319
cases treated, 313 were cured, while six did not get satisfactory
results. 98.1 per cent cured. Radium is used in cases in which
it is necessary to check the bleeding quickly and in those in
which cancer of the fundus is suspected. In cases treated with
X-rays, from 1,200 to 1,800 roentgens was used. The average
amount of treatment being 1,500 roentgens. This variation
depends on the age of the patient and also the thickness of the
parts. This treatment is divided into doses of 300 roentgens
given once each week, alternating one anterior and one posterior
field. The other factors used were from 120 up to 220 kilovolts
and filter from 4 mm of aluminum up to 2 mm of copper and
a 50 cm distance. In cases treated with radium from 800 to
1,200 mg. hours, the average amount being 1,000 mg. hours,
1 mm of platinum and 1 mm of rubber filter were used.

Method of Securing Blood for Analysis—Abrahamson
states that the difficulties encountered in securing blood for
analysis may be obviated by pricking the finger with a lancet
and letting the blood drop onto a petrolatum block with a
depression on it. Slight pressure proximal to the wound or a
rubber band placed round the finger will produce free flow and
as much as 1 cc of blood may be obtained readily. The blood
can then be drawn up into the pipet. The blood will not clot
on the petrolatum in the short time necessary for collection.
A muffin tin consisting of six depressions in a tin plate, is
used in making the petrolatum blocks. The depressions are
filled with melted petrolatum and then set aside to cool. The
contraction of the paraffin in cooling will produce a smooth
depressed surface that serves admirably for the collection of
blood.

Surgical Treatment of Glaucoma—In the analysis of their operative experience on 108 patients during a period of twenty eight months, Woods and Burch suggest the following rigid criteria 1 The corrected vision following operation must at least closely approximate the best vision immediately prior to operation, unless there can be shown to exist a definite cause for the deterioration of the visual acuity totally unrelated to the glaucoma or the operative procedure 2 The field of vision must be maintained at such a point that it compares favorably with the field recorded before operation 3 The intraocular tension must consistently be within the normal range following operation, without the use of miotic drugs Cases in which there has been even a moderate loss of vision, appreciable loss of the visual field or tension ranging over 25 mm on the new Schiotz scale are considered failures The procedure of von Graefe has given the best results in acute congestive glaucoma in a series of fourteen cases A total of ninety-four eyes, diagnosed as glaucoma simplex (chronic primary glaucoma), have been subjected to some type of fistulizing operation A comparison of the total number of trephines and iris inclusions in chronic primary glaucoma, including both white and Negro patients, shows that a successful operative result was obtained in twenty-three of thirty-five, or 65.7 per cent, of the trephined eyes as compared with forty-four of fifty-nine, or 71 per cent, of the eyes subjected to some type of an iris inclusion procedure Of the three cases of acute glaucoma secondary to uveal inflammation in which operation was performed, one case was controlled by a broad iridectomy while two cases were controlled by an iridotaxis Chronic secondary glaucoma differs from acute secondary glaucoma only in its chronicity Seven such eyes have been trephined, with four successes Iridenclisis has been done in thirteen instances, with eleven successful results and two failures Iridotaxis has been done only once, and thus with success An iridectomy produced a good result in one of two cases In the Negro race a trephine, an iridenclisis and a cyclodialysis each failed in one instance while an iridotaxis gave a good result in three of five cases The operative results in

ocular hypertension secondary to thrombosis of the central vein of the retina have been uniformly unsuccessful in a series of nine cases Trephines were done twice, iridenclises and iridotaxes three times each and an iridectomy once Most of these eyes were subsequently enucleated because of pain after repeated operative attempts to control the tension In white children a trephine was unsuccessful in four cases of buphthalmos, an iridenclisis succeeded in four of seven cases, while an iridotaxis gave a good result in one of two cases In the only Negro patient an iridenclisis combined with anterior sclerectomy successfully controlled the tension in both eyes There are only three white patients having glaucoma in aphakia A trephine brought about a good result in one of the cases, while a cyclodialysis failed in two instances Iridotaxis was done twice with a successful issue in both instances

Surgical Consideration of Typhoid Carrier—Lynn suggests that the surgeon lend his efforts to the health department for the further eradication of typhoid There are approximately 158 persons in Maryland who are potential sources of infection, and to these carriers a total of 627 cases of typhoid can be attributed All these 158 carriers were proved to be so by bacteriologic examination A person may be a carrier and a potential source of danger without ever having had the disease This fact adds to the difficulty in the proper management of this group of persons, as it is not common for them to suffer because of their being carriers Over a long course of years the use of intestinal and urinary antiseptics has proved inadequate The procedure of the health departments of some cities and states, among which Baltimore and Maryland are included, is to determine the focus of infection, then it is of the utmost importance to determine whether the typhoid bacilli are present in the bile The surgical management of these persons is advocated The encouraging reports of cholecystectomy by numerous authors has influenced health authorities to seek the cooperation of surgeons in carrying out the operation that has proved most efficient The results following cholecystectomy have been sufficiently encouraging to recommend it, provided a sufficient length of time has elapsed following the attack of typhoid, that it has been proved that the gallbladder harbors the typhoid bacillus, and that the condition of the person justifies cholecystectomy The greatest difficulty encountered by the health authorities is persuading these carriers to submit to surgery, because most of them feel well and present no subjective symptoms It is hard, therefore, to convince them that such an operation would benefit other people So, like all other health measures, it resolves itself into a campaign of education The results obtained by the various authors on the subject show that cures have been obtained in from 80 to 85 per cent of the persons submitting to operation It behooves surgeons to cooperate with the health authorities in this important matter and thereby make a substantial contribution to preventive medicine

Radium in Treatment of Leukemia—Parsons reviews the results of using radium in the treatment of sixteen cases of leukemia. Two of the patients were suffering from chronic lymphatic leukemia and the others from chronic myeloid leukemia. The radium has been applied in large doses to the splenic area, patients usually received a course of treatment once each year. Application was made only (except in one case) to the splenic area of from 250 to 300 mg. of radium screened by 2 mm. of lead, for three daily periods of fifteen hours. By this means treatment is easily administered and produces satisfactory results both on the general condition of the patient and on his blood picture. It is not claimed that radium provides a greater expectation of life than roentgen irradiation, but from the results obtained it is argued that the treatment, being less frequent, is preferred by the patients, that unpleasant and dangerous reactions are both less severe and less constant, and that this form of therapy is quite as effective in the relief of symptoms as roentgen irradiation. The action of radium on the blood picture is discussed and, like x-rays, is shown to influence the immature pathologic leukocytes to a greater degree than the more normal white cells, while anemia is relieved. The presence of severe anemia or of a large number of nucleated red cells is a bad prognostic sign. No cases resistant to treatment have been found, and treatment by radium appears to hold a number of advantages over treatment by x-rays. The results of treatment by radium have on the whole been very satisfactory, especially in the relief of symptoms. After treatment most of the patients have remarked spontaneously that they felt well and have in many cases been able to resume their work. The spleen has diminished in size, weight has been gained, energy has returned, the anemia has improved, digestive disturbances have disappeared, and the white blood count has been improved by the applications. It is difficult to say quite how radium acts. In the selection of cases for radium treatment only two essentials are required: the patient should be suffering from chronic leukemia and the spleen should be enlarged sufficiently to allow the fitting of an applicator.

Acute Anterior Poliomyelitis—Parker says that, out of thousands of cases of acute anterior poliomyelitis observed every year, injury has never been given a position of importance in the localization of the paralysis. Should the site of injury be considered as the determining factor in the localization of the paralysis, a field of interesting abnormal physiology is opened up. It is reasonable to assume that a gross injury to a limb must produce reflex changes in the central nervous system. The problem here is that while the part injured was peripheral in location the damage was central. In this connection the work of Hughlings Jackson comes to mind. Assuming that the spinal cord is affected by an acute disease, it should be reasonable to think that the part first affected would be that disordered as a result of incoming morbid stimuli. Reflex paralysis, a rare clinical syndrome, has been described by Purves Stewart. In this condition a more or less trivial injury determines a motor, secretory and vasomotor phenomenon in a limb. The assumption here is that some reflex change has occurred in the spinal cord determining the paralysis. Admittedly rare, a sufficient number of cases has been reported to make the condition a clinical entity. Some changes must occur in the spinal cord following injury to a limb or other part of the body, and whether these play any part in the determination of the localization of damage to the anterior horn cells in a patient stricken by acute anterior poliomyelitis remains a work for future observers.

Normal Facial Growth in Children—Young bases his remarks on a study of 1,200 children between the ages of 8 and 14 and 100 children between 2 and 5 years. The sexes were about equally represented. The two dental arches, exhibiting what is regarded as morphologically normal occlusion, were selected for measurement. 1 The mode of growth of the face from 2 to 15 years of age follows a uniform pattern in normal children. 2 The proportionate increase in facial growth antero-posteriorly, i. e., facial depth, is greater in the region of the lower jaw than in that of the upper. 3 The proportionate increase in total height of the face appears to be rather less than that in the upper facial height. 4 The increase in upper facial breadth is less in degree than that shown in both facial depth and facial height. 5 The ratio of facial height to facial breadth increases with age. 6 The portion of the dental arch occupied by the deciduous and later by the permanent teeth becomes part of a wider arc but does not increase in length. 7 The vertical axes of growth in the upper part of the face are more closely correlated with one another than with those of the lower part of the face, i. e., the maxillary growth is to some extent independent of mandibular growth. 8 The face widens relatively more in its lower than in its upper region. 9 A relatively long face shows a slight tendency to be accompanied by a relatively high palate. 10 Though the absolute width of the upper dental arch is significantly correlated with the bizygomatic breadth, there appears to be no appreciable association between a relatively narrow face, as expressed by a facial index, and a narrow dental arch. 11 A narrow face shows a tendency to be deep or long anteroposteriorly.

Dysentery in Children—Blacklock and Guthrie are of the opinion that acute ileocolitis (dysentery) in children appears to have increased in recent years, particularly the Sonne type. Infants less than 1 year of age are less frequently affected than older children, but the mortality is higher in the former. Of 215 cases investigated, 193 were examined bacteriologically, of which 112 (58 per cent) yielded dysentery strains (sixty-one Flexner, forty-five Sonne and six atypical). The presence of blood in the feces appeared to favor isolation of the specific organisms, which at times were extremely scanty. The fermentation reactions were not quite constant for the Flexner and Sonne types and serologic testing was considered more reliable for diagnosis, though a few strains were inagglutinable when first isolated. A closer serologic relationship existed between Sonne than between Flexner strains, the latter showing marked heterogeneity. Clinically, Flexner as compared with Sonne infections were generally accompanied by severer toxemic, circulatory and cerebral manifestations. Occasionally Sonne infections were fulminating. At necropsy, pathologic changes were more pronounced in the solid viscera in Flexner than in Sonne infections. The intestinal lesions—catarrhal, membranous and ulcerative—were largely confined to the terminal ileum and colon, except in infants, in whom at times a diffuse enteritis was present. Positive cultures were obtained after death much more frequently from the mucosa of the colon than from any other part of the intestine or its contents.

Subcutaneous Nodule of Rheumatoid Arthritis—Collins examined many nodules from patients with rheumatoid arthritis and compared these with subcutaneous nodes arising in rheumatic fever and as a result of injury alone. From these studies he has attempted to define the pathologic course of the nodule in rheumatoid arthritis and to form an opinion concerning the significance of the changes found. The essential pathology of these structures is a combination of proliferation and degeneration of connective tissues, accompanied by new formation of vessels at the margin of the lesion and by infiltration with lymphocytes and plasma cells. The gross nodule increases in size not only by the growth of a single necrotic focus and the reaction of the cells around it but also by the aggregation of separate foci individually formed by the same processes of proliferation and degeneration. Very frequently early and late stages in the development of these foci may be found side by side in the same piece of tissue. There is strong clinical evidence that traumatic influences determine the sites of occurrence of these lesions, and continued exposure to trauma may play a part in their later development into structures that resemble bursae. Trauma in itself is not responsible for the nodule in rheumatoid arthritis. The early proliferative and degenerative changes of the connective tissue in the rheumatoid arthritic nodule resemble those in rheumatic fever, but in the former proliferation precedes degeneration, which is contrary to the sequence of events supposed by most authors to occur in the nodule of rheumatic fever. The histology of the more fully developed lesion in rheumatoid arthritis is quite typical

of that disease and bears very little resemblance to the lesion of rheumatic fever. The degree of vascular proliferation and of invasion by the polymorphonuclears is much greater in rheumatic fever, whereas the foci of necrosis are larger and the fibroblastic reaction around these foci is much more pronounced in rheumatoid arthritis. Neither lesion bears much resemblance to the changes of the tissue in any other disease, but there is enough evidence to postulate either a close pathologic relationship or a common etiology of these structures. There are many dissimilarities and no evidence that spirochetal infection causes the subcutaneous nodules of rheumatoid arthritis. Bacteriologic examinations were negative. The reactions of connective tissue, blood vessels and small round cells, together with the peculiar degenerations of the connective tissue, suggest that the nodules are fundamentally granulomas arising in tissues whose inflammatory reactions are modified in a manner with which one is still unfamiliar.

Blood Histamine—Code made a study of the substance, acting like histamine, extractable from normal blood by a method modified from that of Barsoum and Gaddum. In the clotted blood of rabbits from 60 to 90 per cent of the total histamine-like substance extracted from whole blood was found in the serum. Plasma and red cells yielded no significant amount of the active substance. The clotting of plasma out of contact with the cellular elements of blood did not alter its histamine equivalent. In the rabbit, the horse, the dog, the goat, the bullock and man from 70 to 100 per cent of the histamine-like substance extractable from whole blood was contained in the white cell layer of the centrifuged unclotted blood. In the process of clotting, the histamine-like substance normally confined to the leukocytic layer of the blood of the rabbit was freed and appeared in the fluid portion of the blood.

*Iodoform in Treatment of Amebic Colitis C Scotti—p 174
Control of Bilharzia Infection by Natural Remedies F G Cawston—p 177

Treatment of Amebic Colitis—Scotti used iodoform orally in the treatment of eight cases of amebic colitis by Castellani's method. A saline purgative (magnesium sulfate from 25 to 30 Gm) was administered and the stools were examined for *Endamoeba histolytica*. Once the presence of the parasite was ascertained treatment was begun by keeping the patient in bed and on a light diet. The iodoform was administered in keratinized capsules of 0.05 Gm for each dose. Beginning with an initial daily dose of 0.05, 0.1 or 0.15 Gm, a maximal daily dose of from 0.2 to 0.3 Gm was reached. The patients thus treated were insistently asked to make known any subjective sensation and any objective phenomena they thought abnormal. At the end of the treatment lasting from twelve to twenty days examination was again made after a saline purgative. Consistently good results were obtained, the symptoms and the endamebas disappeared from the stools. In one case alone, which had also resisted the emetine treatment, the coprologic examination was still positive after the administration

of iodoform, although there was improvement in the clinical symptoms. There were no phenomena of intolerance nor appearance of rash. There were never any signs of irritation in the digestive tract. In one patient with extrasystolic arrhythmia and tachycardia, the iodoform induced an attenuation of the cardiac symptomatology. The results in these eight cases of amebic colitis, subacute and chronic, fully confirm those obtained by Castellani.

New Source of Vitamin A.—In the course of a study of the mode of occurrence and distribution of vitamin A, Lovern and his colleagues found that the viscera (excluding the livers) of the halibut yield abnormally rich oils. The fish were caught in Shetland waters in May this year. The viscera are normally thrown into the sea although they may contain, as in these cases, as much vitamin as the liver and may yield more potent oils.

Chronic Nonleukemic Myelosis.—Hickling uses the term "chronic nonleukemic myelosis" to refer to all patients who present massive enlargement of the spleen due to myeloid metaplasia, in whom the characteristic blood picture of leukemic myelosis is not found. The diagnosis of chronic nonleukemic myelosis depends on the finding of immature red and white cells in the circulating blood, without the great increase in the total number of leukocytes characteristic of leukemia, in a patient with massive enlargement of the spleen. Fifteen of the twenty-seven patients mentioned in the literature in whom splenectomy was performed died within a few days of the operation, and in those which survived, the subsequent course of the disease was not beneficially affected by the operation. There was no resultant striking improvement in the patient's health. Seven cases are reported which the author includes under the title of chronic nonleukemic myelosis. All have been inpatients on at least one occasion at Charing Cross Hospital. He has seen them at intervals of a few months since they first came under his observation. The features common to all the cases are (1) a chronic course (varying from eighteen months to thirteen and a half years), (2) progressive splenic enlargement reaching a great size, and enlargement of the liver, (3) absence of enlargement of the lymphatic glands and (4) the constant presence in the blood of immature myeloid cells during the time under observation, with the constant presence of nucleated red cells in some cases, and their presence at some time in all, even in the absence of anemia. The shortest period of observation was two years. In all cases the blood Wassermann reaction was negative, and

in none was there any family history of splenic enlargement, jaundice or anemia. Certain features occur in chronic nonleukemic myelosis which either do not occur in or are much less common in leukemic myelosis. These are sclerotic changes in the bone marrow, with new bony formation in the marrow cavities of the bones, and the presence of giant cells in association with the myeloid metaplasia, of such size and in such numbers as to form its most striking feature. These two features have been found together in some cases, in others either one or the other has been found, and in others neither has been demonstrated. A high bilirubin content of the blood and a high blood uric acid value are more common in the cases here considered than they are in cases of leukemic myelosis. These two features seem to suggest an increased destruction of blood cells. The danger of surgical intervention (splenectomy) is emphasized by cases collected from the literature and by its effect in one case in the author's series.

Porphyria in Pellagra.—Beckh and his co-workers studied the urinary output of porphyrin in fourteen cases of alcoholic pellagra, two cases of pellagra secondary to infectious disease of the gastro-intestinal tract and three cases of healed pellagra, also as controls in eighteen healthy persons, forty more persons suffering from various diseases other than pellagra, two monkeys with mild nutritional macrocytic anemia and five normal subjects receiving yeast and five receiving liver extract. While the cases of endemic pellagra observed by Ellinger and Dojmi had in the beginning of the disease a high porphyrin output usually disappearing early in remission but always when cured, the porphyrin output of the alcoholic cases in the authors' study showed a greater variation. In most of the latter cases the porphyrin excretion bore a rough relationship to the intensity of the cutaneous lesions and the lesions of the mucous membrane as the patients were watched in their progress toward recovery. On the other hand, among the patients showing no porphyria there were mild cutaneous lesions in three cases and none in one. The greater variability of porphyria in the alcoholic pellagrins may be in relation to the history of alcoholism. Of the sixty-seven control subjects only five showed an increased porphyria, three of whom were receiving iron therapy. The porphyrin present in the cases of pellagra was found to be a coproporphyrin. A similarity is pointed out between the clinical symptoms of acute porphyria and pellagra. One case of pellagra is described which exhibited all signs of an acute porphyria.

Treatment of Urinary Incontinence in Women—Muret and Rapin discuss the treatment of the most frequent form of urinary incontinence in women, which they define as the condition connected with the prolapse of the vagino-urethral wall at the level of the trigono-urethral sphincter with or without local organic lesions and cicatricial adhesions. They discuss the nonsurgical treatment by means of pessaries and cauterization but point out that the preferred treatment is surgical. The most simple and the most generally utilized method consists in suturing widely in the course of an anterior colporrhaphy (perhaps sufficient by itself), the tissues adjoining the region of the exposed sphincter, this suture unites the tissues in the median line, starting from the lateral walls of the pelvis and the pubic arch, the posterior wall of the urethra is thus elevated, supported and approximated to the anterior wall at the level of the sphincter. The muscular suture of the latter can be dispensed with save in exceptional cases. On the other hand, in case of cicatricial adhesions around the urethra and bladder, their liberation is always necessary, this is done almost automatically at the time of the exposure and the mobilization of the region of the sphincter. This operation may suffice but it must always be accompanied by colpoperineorrhaphy and, if necessary, by the other complementary operations of the utero-vaginal prolapse. Depending on the nature of the case, some other intervention may be resorted to. The choice of the intervention depends necessarily on the habits and personal experiences of the surgeon, as is indicated by the great number of methods that have been recommended for the treatment of prolapse. It is essential that the surgeon recognize in each case the cause of the incontinence and select the operative method that is adapted to the pathogenesis of the disorder. There exist a variety and number of methods capable of producing cure in the majority of cases of this difficult and obstinate disorder.

Treatment of Vesicovaginal Fistulas—Andre shows that in the treatment of vesicovaginal fistulas it is necessary to consider the number, the dimensions and the site of the fistulas as well as the condition of the vaginal wall surrounding the fistula. He concludes that in the low obstetric fistulas it is best to operate by way of the vagina, dissecting the vagina from the bladder, with temporary cystostomy which intervention in case of failure can be repeated. In cases of high obstetric fistulas, the subpubic route is indicated, either at once or after failure of attempts by the vaginal route. In operative fistulas, the transvesical approach has produced numerous successes and has in its favor its harmlessness for which reason it has been employed by the majority of surgeons, according to the technic of Marion. It should be kept in mind however, that the transperitoneal vesical method of Legueu, although it involves risks, has produced a higher percentage of cures than all other methods. It has the advantage of making possible the detection and removal of intestinal adhesions to the bladder. In vesicocervico urethral fistulas the best results seem to have been obtained by the creation of an artificial canal by means of the trocar method of Marion, following total closure of the bladder and temporary cystostomy. This method produced better results than the flap procedures from the point of view of continence and of urinary functioning. In the large fistulas the procedures which employ the interposition of the neck of the uterus have found no imitators in France. In the irreparable fistulas or in those which resist several attempts with other procedures, colpocleisis is only a makeshift, for its inconveniences are well known. Finally, if for any reason whatever one must take recourse in diverting the urine away from its natural course the author prefers to the intestinal route of Coffey, which is grave in its immediate and late results the iliac cutaneous derivation of Papin, which is less dangerous and likely to result in a long survival. In the conclusion the

author points out that, thanks to the progress in obstetrics and operative gynecology, vesicovaginal fistulas are becoming more and more rare.

*Existence of Hematopoietic Hormone in Hypophysis J Flaks I Hummel and A Zlotnik—p 1261

Hematopoietic Hormone in Hypophysis—Flaks and his collaborators maintain that the hematopoietic function of the bone marrow is regulated by a hormone, although its character and origin have not been definitely established. Clinical and experimental observations indicate that the hypophysis exerts an influence on the hematopoietic function of the bone marrow, and the authors decided to investigate that problem also. They experimented on rats by injecting extracts of the anterior lobe of the hypophysis. In summarizing the experiments they state that 1 The prolonged oral administration of the anterior lobe of the hypophysis produces in rats an increase in the number of reticulocytes and consecutively an augmentation in the erythrocytes, so that the number of erythrocytes which is normal for this species of animals is considerably surpassed. There results a prolonged experimental polyglobulism. 2 The substance which irritates the bone marrow and provokes strong erythrocytosis is not found in the deproteinized fraction and it is thermostable. 3 This hormone acts directly on the bone marrow and is without influence on the thyroid. 4 The injection of a quantity of extract corresponding to 0.4 Gm of fresh hypophysis produces after twenty-four hours the transformation of gray marrow into red marrow. 5 On the basis of clinical observation and of the experiences described the authors conclude that the hypophysis has an important physiologic role in the regulation of erythropoiesis by means of a hematopoietic hormone which acts on the bone marrow.

The Adrenal Cortex and Disturbances in Resorption—Verzar cites experimental and clinical observations which prove that the adrenal cortex exerts an influence on intestinal resorption. He shows that the resorption from the intestine is essentially a process of diffusion. The question arose whether esterification ceases in the intestine as it does in the musculature when the adrenals are extirpated. It was demonstrated that removal of the adrenals arrests the selective resorption of certain sugars. That the abolition of the function of the adrenal cortex was the decisive factor was proved by the fact that the administration of adrenal cortex extract reestablished the selective resorption for certain types of sugars. It was demonstrated that fat resorption is greatly retarded in adrenalectomized animals and that animals without adrenals fail to grow because they are incapable of forming flavin phosphoric acid from lacto-flavin. When young adrenalectomized rats were given flavin phosphoric acid they continued to grow. The author further investigated whether in human subjects disturbances occur which must be regarded as primary disturbances in resorption and in which involvement of the adrenals is demonstrable or whether disturbances in the resorptive processes can be demonstrated in adrenal disorders. He was able to demonstrate that nontropical sprue and Gee-Herter's disease show the same inhibition in the resorptive function that is observed after abolition of the adrenocortical function. The literature reports cases of nontropical sprue that were diagnosed as Addison's disease, also cases in which sprue followed Addison's disease and vice versa. The author emphasizes that the otherwise inex-

plainable disturbances in resorption which develop in these disorders are the result of a hypofunction of the adrenal cortex. Regarding the action of adrenal cortex extract in disorders in which the primary resorption has been impaired, he says that in nontropical sprue and similar disorders the adrenal cortex extract has never been given in doses large enough to be comparable to those that were effective in animal experiments. However, yeast concentrates that contain flavin-phosphoric acid have been known to produce favorable results in nontropical sprue. Moreover, the author thinks that the lack in vitamins, which has been held responsible for sprue, is the result of a defective function of the adrenals, for adrenalectomy is followed by a secondary B. avitaminosis.

Fulminating Purpura—Glanzmann points out that the term purpura fulminans was applied by Henoch to cases in which hemorrhages from the mucous membranes were entirely absent but in which extensive ecchymoses developed with great rapidity. Within a few hours the ecchymoses colored entire extremities blue or blackish red and caused a rather firm hemorrhagic infiltration of the cutis. Moreover, serosanguineous blisters formed on the skin, but there never was gangrene. In some cases hardly twenty-four hours elapsed between the formation of the first ecchymoses and death. The longest duration was four days. Complications were absent and necropsy gave negative results, except for a generalized anemia. The etiology likewise remained obscure in Henoch's cases. One of the cases developed after a pneumonia and another one after a mild scarlet fever, whereas in all others the etiology was entirely obscure. After reviewing several other cases of fulminating purpura that were reported in the literature, the author gives a detailed description of a case that he observed in which a nursing, aged 6½ months, recovered. In 1916 the author suggested that the fulminating purpura of Henoch represents the severest form of anaphylactoid purpura. The bilateral, symmetrical arrangement of the ecchymoses recalls similar conditions in Schonlein-Henoch's purpura. In the reported case, successive crops appeared in which, in addition to the blood spots, red papules with urticarial aspects developed and also pale, inflammatory edemas. The condition of the blood of the nursing corresponded with that observed in anaphylactoid purpura. For the treatment the author recommends blood transfusions or, still better, intramuscular blood and serum injections, to effect desensitization. In this case the treatment with calcium gluconate and cevitamic acid resulted in rapid cessation and paling of the extensive cutaneous hemorrhages. However, the favorable effect of the cevitamic acid should not be regarded as indicative of a scorbutic genesis of the cutaneous hemorrhages. The vitamin C merely supports the calcium action by making the vessels less permeable. It is pointed out that recent studies have disclosed that vitamin C inhibits or reduces anaphylactic shock and serum disease.

C. Guarini—p. 41

Short Waves in Chronic Sinusitis—Taha reports satisfactory results from the treatment of nasal or paranasal sinuses by short waves in chronic sinusitis. He used waves 7 or 8 meters long and Schliephake electrodes of the condensing type in eight patients suffering from chronic maxillary, frontal or sphenoidal sinusitis. In chronic unilateral maxillary sinusitis the electrodes are placed over the sinus which is involved by the pathologic process and on the contralateral occipital region. In chronic bilateral maxillary sinusitis the electrodes are symmetrically placed over each sinus. They should entirely cover the sinus. In frontal and sphenoidal sinusitis the classic occipitofrontal and bitemporal techniques, respectively, are indicated. When various sinuses are involved the treatment is given alternately to the different sinuses. The treatments are given daily or every other day, up to thirty or forty during two or four months. Each treatment lasts for fifteen minutes

during the first month or two months and for thirty minutes (and rarely for forty minutes) during the last month or two months. The treatment is discontinued for ten days at five intervals. According to the author the treatment is of value especially in chronic sinusitis of short duration. Maxillary sinusitis, especially of the inflammatory and suppurative form, responds to the treatment better than other forms of chronic sinusitis. Suppuration is replaced by a serous discharge which completely disappears shortly in the course of the treatment. Fever, headache, local pain to pressure and local congestion promptly disappear. In some cases there is a transient slight aggravation of the symptoms early in the course of the treatment. The patients who do not respond favorably to the short wave treatment do not improve under medical treatment either and therefore should be subjected to surgery. The author advises cooperation between specialists in otorhinolaryngology and dentists, as the presence of caries or other dental diseases may maintain inflammation of the sinuses. When the x-ray examination of the sinus shows destruction of the bony walls together with inflammation, surgical intervention is indicated. The results obtained in the author's cases were verified by x-ray examination of the sinuses some time after completion of the treatment.

Influence of Cevitamic Acid on Metabolism of Uric Acid—Pescarmona and Quaglia studied the influence of cevitamic acid on the metabolism of uric acid and urea in four normal persons, six patients presenting hyperuricemia and five with hypo-uricemia. All were given a constant diet which contained a specified amount of purine substances. Quantitative determinations of the uric acid in the blood of the patients with a fasting stomach were made for seven or nine consecutive days. The last four or five days they were repeated one half, one two and three hours after administration of an intravenous injection of 150 mg of cevitamic acid. Determination of uric acid in the blood was made as soon as possible after withdrawal of the latter in order to prevent alterations in the blood. The amount of uric acid and of uric acid eliminated through it was determined in the twenty-four hour urine. The uric acid in the blood and in the urine was determined by the Benedict colorimetric and the Folin-Shaffer methods, respectively. Urea in the urine was determined by Segre's sodium hypobromite method. The authors found that the amount of uric acid in the blood increased in the majority of the cases both during the three hours immediately following administration of the cevitamic acid and during the whole time of treatment. The increase is real. It is not due to the amount of cevitamic acid in the plasma after the injections. Diuresis is increased in the majority of the cases. The daily elimination of uric acid and urea in the urine increased in all cases. According to the authors, the increase of uric acid in the blood and in the urine as well as that of urea in the urine is due to an indirect stimulation of the uric acid and urea metabolism by cevitamic acid. Probably the latter stimulates the sympathetic nervous system and the production of ferments which activate the metabolism of purines as well as of urea.

*Objective Method for Determination of Onset and Duration of Coagulation H. Festen—p. 1370

So-Called Mutilating Arthritis J. Schuller—p. 1381

Determination of Onset and Duration of Coagulation—In his studies of thrombosis, Festen needed a method that would determine not only the onset of the coagulation of the blood but also the time of its completion. Moreover he had a need

at finding a test for which a few drops of blood would suffice. Attempts were made with the determination of the electrical resistance before and after coagulation. Differences in the conduction capacity of the blood for electric current were actually determined, but, in view of the disadvantages of this method, it was abandoned. One of the disadvantages was that the electric current influenced the speed of coagulation. A report by Wolvius gave the author a new idea. Wolvius attempted to determine the coagulation time by means of the thermo electrical effect, when the blood coagulates, it becomes less permeable for heat rays, which can be determined by means of the extincitometer of Moll. However, the Wolvius method could be used only on the blood plasma, not on the whole blood, and for this reason it was necessary to subject the blood to interventions, such as centrifugation, which would influence the coagulation time. It occurred to the author to use the photo cell, because it permits the measurement of weaker rays than do the thermic methods. He puts two drops of blood, which have been mixed with one drop of distilled water, on a hollow slide and places it directly in front of the photo cell. By means of micro-ammeter, it is possible to determine after four or five minutes that the photo cell receives less light, this reduction in light is at first considerable, after a few minutes it becomes less, but after from thirteen to sixteen minutes the light again becomes uniform. By recording the position of the amperemeter at half minute intervals, a curve is obtained which indicates the changes in the light permeability of the blood during coagulation. That this change in the permeability for light is the result of coagulation is proved by the absence of changes in the permeability for light when instead of the drop of distilled water one of sodium citrate is added. In order to make the method even more objective, the movement of the needle was registered by photography. An advantage of the method is that the blood is not touched during the process of coagulation.

*Hepatic Involvement in Exophthalmic Goiter Leonore Retzlaff—p 527

Unusual Forms of Polycythemia Vera—Seggel states that of twenty-eight cases of true or idiopathic polycythemia that came up for observation at the medical clinic of the university of Leipzig there were only a few that were of the Vaquez or Gaisbock type. A case which is described in detail induced him to watch for a tendency to thrombosis and to hepatic disturbances in cases of polycythemia vera. Reviewing the literature, he found that hepatic cirrhoses may concur with a simultaneous increase in erythrocytes in the circulating blood. Some of these cases were regarded as secondary polyglobulism, others as a combination of polycythemia and hepatic cirrhosis. Such combinations may exhibit symptoms like the described case. Thromboses in the region of the portal vein are occasionally observed in patients with polycythemia. Moreover, such thromboses have been observed also in cases in which there is hepatic cirrhosis. The author thinks that these thromboses are most likely the result of the well known tendency to thrombosis, which exists during polycythemia. The opinion formerly often expressed namely, that thromboses in the region of the splenic vein may be the cause of polycythemia, has been abandoned. A thrombosis in the region of the portal vein may be without clinical symptoms, or it may become manifest by ascites and by the development of a collateral circulation but if it develops suddenly and extensively and produces intestinal infarcts it may result in death. Ascites develops in polycythemia either in case of a simultaneous cirrhosis of the liver or in the presence of thrombosis of the portal vein or without such thromboses in the presence of disturbances in the hepatic circulation. Such circulatory disturbances in the liver are the

chief cause of ascites in cases of thrombosis in the region of the portal vein. Icterus is often found in those cases of polycythemia in which there is also ascites, the icterus is likewise usually the result of a hepatic circulatory disturbance.

U Wave in Human Electrocardiogram—Blumberger directs attention to the fact that in the human electrocardiogram the T wave is occasionally followed either by a flat or a steep deflection, which was observed by Einthoven and was designated by him as U wave. So far it has not been determined whether this U wave is of cardiac or of extracardiac origin (perhaps elicited by the large vessels). In electrocardiographic tests on 240 patients, the author discovered the U wave twelve times (5 per cent). It may be present in all leads from the extremities and in the thoracic lead, or only in one or some of the leads. It may be absent in the electrocardiogram that is taken during rest and present in the one that is taken after exertion. It is usually more noticeable in the latter. Treatment with strophanthin or the presence of myocarditis does not influence an existing U wave. The size of the U wave is independent of the T wave. The U wave may enter into the P or T waves and thus may simulate intra-auricular conduction disturbances or changes in the T wave. It may prove difficult to differentiate the U wave from the electrocardiographic signs of auricular flutter. In the author's material a comparatively large number of the patients with U wave had myocardial disorders and high blood pressure.

Hepatic Involvement in Exophthalmic Goiter—Retzlaff reviews the literature and describes five cases that were observed at the university clinic in Königsberg. Although the literature indicates that a knowledge of a toxic impairment of the liver is based chiefly on pathologic anatomic studies, the cases reported here indicate that in all of them the signs of hepatic impairment were already demonstrable during life. Icterus the most typical symptom, and an increase in the bilirubin content of the blood were present in three cases. The fact that in two of these three cases the condition improved again indicates that the icterus which develops during exophthalmic goiter does not have the unfavorable prognosis (fatal outcome) that has generally been ascribed to it. On the basis of clinical studies and necropsies the conclusion is reached that parenchymal and functional disturbances of the liver are not a rarity in patients with exophthalmic goiter but that they can be observed occasionally, especially in the severe forms of exophthalmic goiter.

*New Treatment of Urticaria and Quincke's Edema G Wolpe—p 1257

New Treatment of Urticaria and Quincke's Edema—Wolpe evaluates the customary treatments of urticaria and Quincke's edema, suggests that the two conditions might be related and directs attention to the difficulty in keeping all allergic substances away from sensitive patients as well as to the difficulties involved in specific desensitization. He made efforts to find a substance by which the cutis and subcutis (the system especially involved in urticaria and Quincke's edema) could be desensitized not only against the substance itself but also against other urticarogenic substances. He reports the history of a woman, aged 40, who was subject to urticaria and who, after having been stung by a bee, developed a severe anaphylactoid urticaria which spread over the entire body. The urticaria responded to the intravenous administration of calcium. However to free the woman from the predisposition to urticaria, the author tried desensitization with a bee venom preparation. Although it was feared that a new anaphylactoid urticarial attack might be elicited by the preparation, this was not the case and the desensitization was successful in that, although formerly the woman had had urticarial attacks every six or eight weeks during the five years following the desensitization,

during which the patient remained under the author's control, she remained free from urticarial attacks in spite of the fact that her food was not restricted and that she was occasionally stung by bees or wasps. Encouraged by this success, the author tried desensitization with bee venom in twenty-five other patients with urticaria. Of these, fifteen remained entirely free from attacks thereafter, in six the attacks became less frequent and milder, and the four others could not be found for further control. After having used the bee venom desensitization for a year successfully in urticaria, the author decided to try it also in Quincke's edema. He describes the history of a man in whom the intravenous bee venom therapy not only cured the existing attack but prevented relapses of the allergic disorder. In the subsequent four years the author treated successfully five other cases of Quincke's edema by means of bee venom therapy. He suggests that the capacity to effect an organ specific desensitization probably is not restricted to bee venom preparations, but that this effect might be elicitable also with other cutaneously active, urticariogenic substances.

Insatiable Pneumothorax—Tenenbaum recommends Forlani's method for pneumothorax, which requires in the physician not only skill but the utmost concentration to avoid complications, one of which is insatiable pneumothorax in which the injected air unaccountably disappears. Among twenty-five such patients it was noted that the pleural exudation did not amount to more than 4 per cent, while the ordinary pneumothorax patients reached an exudation of from 50 to 100 per cent. Insatiable pneumothorax is rare and can be diagnosed only after exclusion of partial ordinary pneumothorax. It is observed not only in incipient tuberculosis but also in rather severe cases. To change it into ordinary pneumothorax, air must be pumped in repeatedly and atropine must be administered. The mechanism of appearance of insatiable pneumothorax is still unknown and the diagnosis remains an open question. He classifies insatiable pneumothorax into three groups: (1) early (primary) and late (secondary), (2) genuine and spurious, which is divided into the masked and partial forms, and (3) that in which mistakes have been made in the administration of pneumothorax: penetration of the lung by the needle and subpleural injection of air.

Heterogenous Blood Transfusion in Gastro-Intestinal Diseases—Ryss reports a follow-up study of 190 cases of ulcerative disease of the stomach in which heterogenous blood transfusions were given, and of 120 cases in which treatment was administered by transfusions of homogenous blood. The cases were followed for four years. In the patients treated by the transfusion of heterogenous blood the immediate results were excellent in 76 per cent, satisfactory in 17.5 per cent and without any effect in 6.5 per cent. However, 70 per cent of the patients exhibited recurrences in from six to eighteen months after the termination of the treatment and the disappearance of clinical signs. Immediately after transfusion of either

homogenous or heterogenous blood, a marked lowering of the alkali reserve was noted the stronger the reaction, the more marked the lowering. This effect corresponds to similar observations made in anaphylactic shock by other authors. The alkali reserve toward the end of the treatment increased once more from 19 to 139 with homogenous blood and from 06 to 24.5 with heterogenous blood transfusion. The increase in alkali reserve always coincided with improvement in the clinical signs and for that reason may be regarded as a positive index of the therapeutic action of blood transfusion. The basal metabolism rose sharply following the transfusion. After each blood transfusion it fell somewhat in the course of the treatment, so that at the end of the treatment it was higher by from two to thirteen points than it was at the beginning. The author considers the rise in the basal metabolism toward the end of the treatment as an index of an increase in the intensity of the biochemical and immunobiologic activity of the cells of the organism. Because of recurrences, the author is forced to the conclusion that the heterogenous and homogenous blood transfusion therapy in ulcerative disease is just as ineffective as the other methods of treatment. The therapy is to be recommended in protracted forms of ulcerative disease in which dietetic treatment does not accomplish anything. In the bleeding type of an ulcer, transfusion of homogenous blood is the most effective, in fact, the best treatment, and is absolutely indicated. The experience with blood transfusion therapy in sixty cases of colitis demonstrated that the method is frequently quite successful, particularly in cases of chronic dysentery and amebic colitis, in which vaccines, emetine and other specific remedies fail to produce an effect.

Transfusion of Conserved Blood—Filatov points out the following advantages of the method: 1 Its availability in emergency and the saving of time should make it of particular value in military surgery. 2 Conserved blood can be transported to distant localities. The Leningrad Central Institute for Blood Transfusion has transported blood in airplanes in 130 instances, the blood being delivered by parachutes. 3 Transfusion of conserved blood is limited to one act, namely, that of transfusion. It calls for less skill than the taking of the blood from the donor. One must, however, guard against overheating the blood, for transfusion of such blood is dangerous. 4 The method of using conserved blood is responsible for the increase in sources of the blood. Thus it made possible the utilization of placental and of cadaver blood, as well as transfusion of plasma. 5 The method allows of greater flexibility in dosage. One may resort to massive transfusions as well as to small ones, as the case may indicate. The institute keeps on hand blood in amounts of 300, 200, 100, 20 and 10 cc, the small doses being for hemotherapy in pediatric practice. The most serious shortcoming of the method is to be seen in the definite lowering of the biologic properties of the conserved blood. The time limit accepted by the institute for the preservation of the blood is ten days. This limit may be extended to fifteen days in exceptional cases and when the blood is not to be transported. Another disadvantage is to be seen in the fact that a certain number of samples of the blood will spoil and will have to be discarded thus increasing the cost of transfusion. Finally, the author states that the transfusion of conserved blood is associated with more complications than the transfusion of fresh blood. He concludes that the method is now past its experimental stage and that it deserves a wider application.

*Pathogenesis of Renal Glycosuria C. J. Munch Petersen—p. 883

Remarks on Pathogenesis of Nasal Lupus H. Videbeck—p. 891

Renal Glycosuria—In the opinion of Munch Petersen, the hypothesis of cerebral origin of renal glycosuria is supported by the fact that renal glycosuria is most often combined with an increased dextrose content in the spinal fluid and that the sugar content of the spinal fluid in renal glycosuria reacts in a manner characteristic of dysfunction of the subthalamus region. Further, in most of the cases of renal glycosuria examined by him there were organic disorders in the central nervous system.

LOCAL OVERGROWTH

CHAIRMAN'S ADDRESS

FREMONT A CHANDLER M.D.
CHICAGO

During the past decade orthopedic surgeons have evidenced a mounting interest in the problem of the short extremity in its relation to the functional economy of the body. From every side come studies relating to the causative factors as well as proposals of corrective measures designed to reestablish or equalize the length of the extremities. The ultimate goal of these procedures is the conservation of effort and work on the part of the body. Defective growth due to (1) deficiency of germ plasma, (2) circulatory failures occurring early in embryonic life or (3) epiphyseal disturbances resulting from some obscure endocrine failure disease trauma or dyscrasia is encountered in the everyday practice of orthopedic surgery.

The bilateral manifestation of arrested growth arouses our deepest and most sympathetic consideration and spurs us on to experiment in fields of medicine which are still somewhat nebulous to most orthopedic surgeons, e. g. endocrinology and vitamin therapy. Surgical procedures are rarely advocated for the relief of bilateral symmetrical arrest of growth, for the pitfalls are many and the results seldom justify the means.

In dealing with unilateral arrest of growth and the accompanying disturbances of posture and function, the orthopedic surgeon, especially, has been inspired to employ an endless variety of mechanical and surgical measures in reaching a physiokinematic as well as a cosmetic solution for his patient. These measures extend from the use of artificial appliances originating in antiquity to the more modern and direct surgical procedures of leg lengthening and growth stimulation in all its phases, as well as the contralateral shortening and epiphyseal arrest of the normal extremity. The success of leg lengthening has been demonstrated frequently, its failures and untoward results less often. Growth stimulation appeals to us, although the perfect stimulus remains to be discovered. Shortening of the well leg is successful beyond doubt. Epiphyseal arrest of the longer extremity by surgical measures is most effective and less hazardous and is gaining rapidly in its field of usefulness.

Because the skeleton is the most concrete and permanent register of disturbances in growth the orthopedic surgeon is placed in a position to observe the life story of his patient as he views the progress of skeletal development clinically and roentgenologically.

The counterpart of arrested growth is overgrowth, and it is to this subject that attention is here directed. Here again, the orthopedic surgeon's opportunity is unique, for the skeletal register runs true to form. The same problem of conservation of energy is present, and the corrective measures at the disposal of the orthopedic surgeon are similar to those used in dealing with arrested growth. That overgrowth may follow trauma to growing bone is not an uncommon observation. So frequently does such overgrowth occur that the orthopedic surgeon makes inquiry into this factor whenever inequality in the length of the extremities is encountered. The spontaneous self lengthening of overriding fractures at times compensates for what might otherwise appear as gross inefficiency of treatment. This is especially so in the lower extremity. The factors causing overgrowth although somewhat obscure are related to the growth response at the site of fracture and probably, more directly, to compensatory vascular engorgement near the active epiphyses. Epiphyseal stimulation following osteotomy was observed by Goldthwaite and more recently by Furgeson. The outcome of these observations is the development of epiphyseal stimulation by the production of pseudo-fractures near the epiphyses. Foreign material and chemical irritants have been employed to the same end. That growth stimulation may follow the removal of a cortical graft is obvious (fig 1), but is often not observed in view of the overshadowing pathologic change for which the graft is taken. The possibility of overgrowth of the tibia might be of help in the selection of the extremity from which the graft is to be moved.

Infections of the shaft of growing bone stimulate growth at the epiphyses provided the function of these centers of growth is not impaired. The localized overgrowth in osteomyelitis or in the more limited Brodie abscess may be such as to result in gross inequality of limb and its complications.

Infections of joints if not widely destructive stimulate epiphyses to greater activity, first, in the lengthening of the diaphysis and, second, by increased osteogenesis in the subchondral area of the epiphysis itself. Low grade rheumatoid arthritis of the wrist of a small child will result in ossification of the carpal bones more advanced than that of the uninvolved member. The patella responds in a similar manner. This epiphyseal response may occasionally be seen in tuberculous joints. It is absent of course in the case of virulent destructive lesions of joints.

Carey and others have shown that bone grows in response to elements of traction or compression and that the contour and architecture of osseous bodies reflect to a great degree external forces. The angle formed by the shaft and the neck of the femur is a composite of growth reaction in response to the tension

and traction of the hip muscles and the compression force of weight bearing occurring throughout the normal arcs of function. Should the arc of function be restricted, alteration in the angle of the femoral

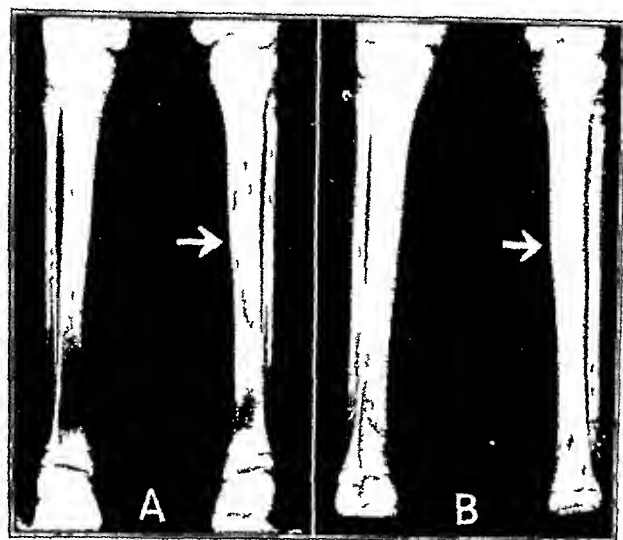

Fig 1—A cortical graft removed from the left tibia. B 2 cm overgrowth in length sixteen months after removal of the graft.

neck may be anticipated. I have observed the development of coxa valga in cases of prolonged immobilization of the knee joint by cast or, more recently following operative ankylosis (fig 2). In such cases the functional arc is reduced considerably and the resulting coxa valga increases the length of the leg. This is especially so when the stimulus of weight bearing is not interrupted over long periods. Such a process may be considered as one phase of local overgrowth in a somewhat restricted sense. In cases of fusion of the ankle for tuberculosis in children, stimulation of tibial growth has been observed when the plaster dressing was applied in such a way as to increase longitudinal compression strains, that is with the knee flexed at right angles.

Fig 2—Coxa valga on the right side three years after surgical fusion of the knee for tuberculosis.

tions remains high. Their observations were on chick embryos which had been exposed to the roentgen ray. Local overgrowth due to defective germ plasma may be manifest by an unending variety of deformities

such as hemihypertrophy, polydactyly and some form of macrodactyly. Each case of this kind presents a problem taxing the resourcefulness of the surgeon in charge (figs 3, 4 and 5).

Streeter has shown that differentiation of the limb bud may be distorted or arrested by local arrest of the embryonic circulation. The association of local over

Fig 3—Overgrowth of the toes, no associated vascular anomalies.

Fig 4—The feet shown in figure 3 after surgical intervention.

growth of tissue with maldevelopment of the vascular system has been emphasized by many writers. Keith described the origin of these systems as follows:

Within the body of the embryo mesenchymal cells assemble in vasoformative groups, becoming canaliculated they unite with neighboring groups to form arteries and veins. The endothelial

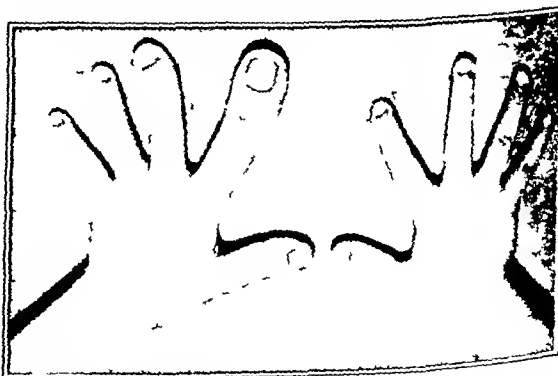

Fig 5—Overgrowth of the thumb and the index and middle fingers of the left hand.

cells of capillaries retain throughout life the vasoformative power which characterizes them during the period of development and growth. The formation of lymph vessels begins in definite centers from which vessels spread outward, vascularize and drain a definite area. Hemangioblasts are everywhere at birth and by the fourth week have vascularized all embryonic tissue. The lymphangioblasts, however, do not vascularize tissue until the sixth to eighth week or later, at first forming lymph sacs which are temporary structures but which eventually

ally open into the jugular vein or the thoracic ducts. The lymphatic system is a closed system, its walls being lined with endothelium. No communication with tissue spaces exists.

Alterations in the rate of growth may be due to the increased circulation of intercellular fluid or possibly to the increased temperatures which are found. Inter-

cular nevus formation. My observations of cutaneous temperature in areas of nevus show that an elevation of 2 degrees C (36 F) above the temperature of adjacent normal skin is not uncommon (fig 8). Under

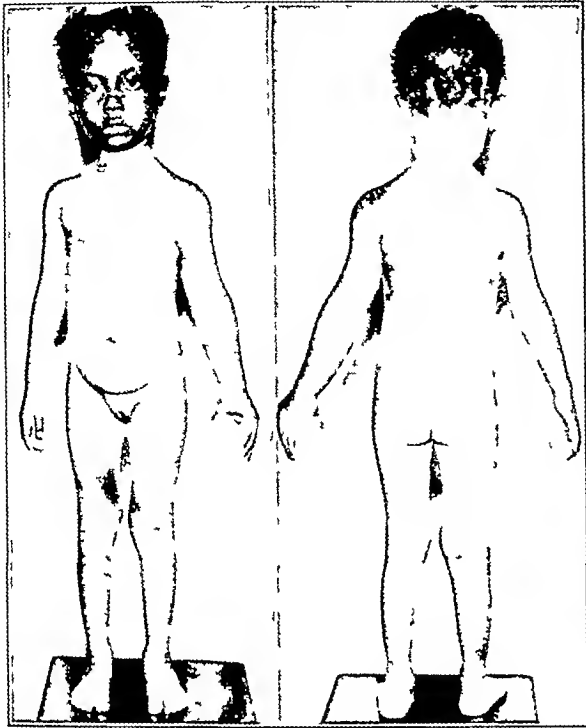

Fig 6—Overgrowth of the left arm with congenital deformity of the hand associated with anomaly of the base of the heart

communications between the larger vessels (arteriovenous fistulas) result in a distinct elevation of the oxygen tension of the blood, especially in the venous

Fig 7—Enlargement of the base of the heart on the left side (see fig 6)

system. All portions of the extremity involved develop at an accelerated rate of growth. This rate continues until growth ceases or compensatory mechanisms fail and gangrene supervenes. The observations of Ghormley and Horton have been most valuable in this connection. Such fistulas occur at any level and have been observed at the heart itself (figs 6 and 7). The extremity affected

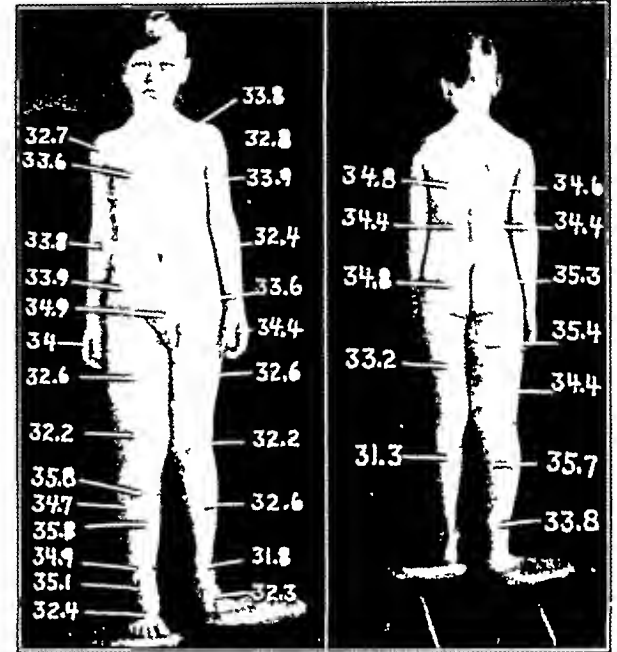

Fig 8—Overgrowth of the right leg with extensive nevus formation. The figures give the cutaneous temperature in degrees centigrade

these conditions growth is excessive. The faulty development of the vascular tree points to some factor active in the fourth week of embryonic life. When this factor continues over a longer period or develops somewhat later in embryonic life, distortion of the lymphatic system may complicate the picture. Arteriovenous

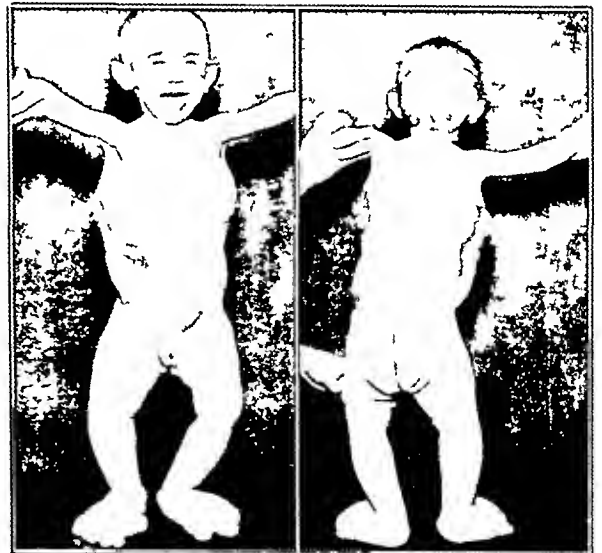

Fig 9—Overgrowth of the feet and legs associated with nevus, lymphangioma and hemangioma. Congenital location of both hips is present in this case

fistulas, vascular nevus, hemangioma and lymphangioma may be present in the same person and serve as the basic factors in causing overgrowth of the extremity (fig 9). Some of these factors undoubtedly are

involved in the production of the clinical picture described by Milroy

Lymphatic obstruction by parasites may also cause overgrowth of the involved extremity, provided of course that infection occurs in the period of growth

Fig 10—Overgrowth of the entire spine etiology factors unknown

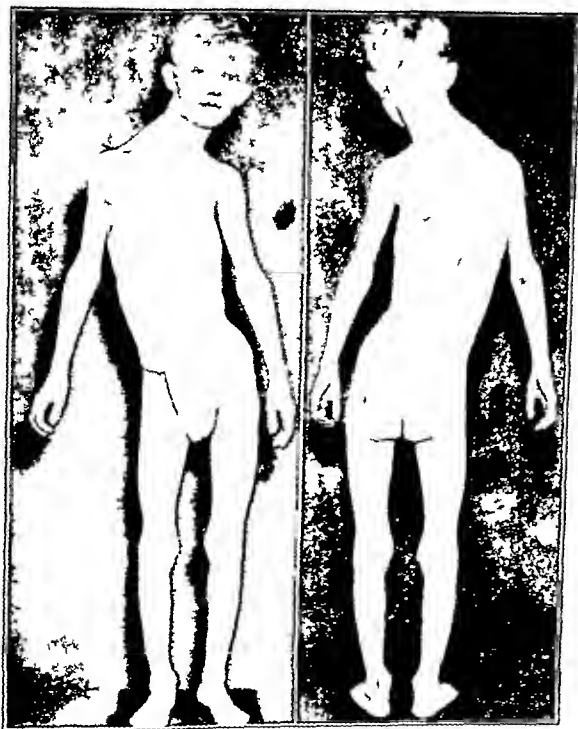

Fig 11—The patient shown in figure 10 four years later. Corrective measures could not be continued because of massive collapse of the lung on three occasions

Endocrine disturbances may be somewhat selective in their effect on different portions of the skeleton but in general local overgrowth is uncommon (figs 10

and 11) Growth hormones, however do have a selective effect, as evidenced by the varying rate of growth of skeletal tissue. The continuing growth of the spine after the slowing of the growth of the extremities, at puberty points to a selective growth action or to a more complex and varying composition of the growth hormone itself. Imbalance of the normal response of skeletal tissues to this stimulus may result in local overgrowth.

The parade of deformities passing before the orthopedic surgeon cannot but arouse his curiosity as to the etiologic factors at work. His high development of surgical technique along mechanical lines too often leave him barren of the deep principles familiar to the physiologist. To do justice to his calling, the orthopedic surgeon must think more along physiologic lines. This is one of the guide posts to greater usefulness. Let him heed it.

THE MANAGEMENT OF PULSION ESOPHAGEAL DIVERTICULUM

BASED ON AN OPERATIVE EXPERIENCE WITH EIGHTY-TWO CASES AND A FOLLOW UP STUDY OF FIFTY-THREE CASES

FRANK H. LAHEY, M.D.
BOSTON

Having operated on eight-two patients for esophageal diverticulum of the pulsion type, having had a number of intrapleural esophageal diverticula of the traction type to deal with by nonoperative measures and having successfully operated on a large intrapleural supradiaphragmatic type of diverticulum, I thought it possible that a presentation of some of the knowledge obtained in these experiences would prove of interest and of value.

Pulsion diverticula far outnumber all other types of esophageal diverticula according to my experience, and occur as small (fig 1) intermediate (fig 2) and large (fig 3) diverticula always located, since they are the result of a bulging of esophageal mucosa through a congenital muscular defect at this point, at the oesophagopharyngeal level.

Traction diverticula (fig 4) are most commonly situated within the pleura and at or near the level of the main pulmonary bronchi, since they are associated with inflammatory processes in the bronchial lymph glands located at this level.

Supradiaphragmatic intrapleural esophageal diverticula probably start as the result of a congenitally weak area in the esophageal wall and develop further into large sacs, as shown in figure 5 because of the accumulation of food within the sac and an intrasac pressure which is greater than the resistance of the wall of the sac.

This discussion is concerned for the most part with esophageal diverticulum of the pulsion type. Since little except dilation need be done for patients with the traction type of diverticulum, and since the intrapleural supradiaphragmatic type of esophageal diverticulum is so much less common than the pulsion type, discussion of these two types will be left for another paper. Figure 6 shows the operative procedure by which

large intrapleural supradiaphragmatic diverticulum was successfully managed and figure 7 the results of the operation

A pharyngo-esophageal diverticulum is a protrusion of the mucosa and submucosa of the hypopharynx through the muscular wall of the hypopharynx. The sac lies between the pretracheal and prevertebral fascia, and its neck is surrounded by fibers of the inferior constrictor muscle and the muscle which splits off from it obliquely to extend down the esophagus, the cricopharyngeus muscle. This muscle's relationship to the neck of the sac is of the utmost importance since unless the constricting muscle fibers about the neck of the sac are accurately removed the sac is quite apt to recur.

The symptomatology of pulsion esophageal diverticulum is, as would be expected related to accumulation of food within the sac and related to obstruction to the passage of food into the esophagus beyond the sac. Dr Walter B Hoover of the otolaryngological section, in reviewing the histories of fifty-three patients operated on in two years in the Lahey Clinic found the symptoms to be in order of frequency difficulty

Fig 1—A small esophageal pulsion diverticulum

Fig 2—A medium sized esophageal pulsion diverticulum

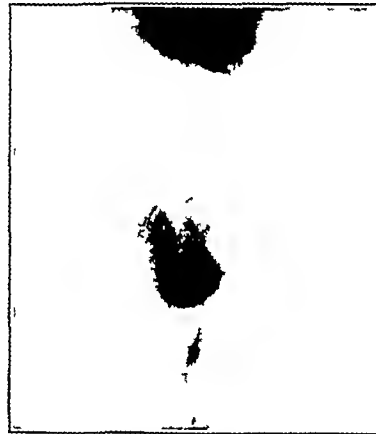

Fig 3—A moderately large esophageal pulsion diverticulum

in swallowing, regurgitation gurgling noises in the neck, choking attacks of strangling or coughing and loss of weight.

Little need be said regarding most of these symptoms. Some points about two or three, however, do need discussion. It is of interest that forty of the fifty-three patients observed by Dr Hoover had gurgling noises in their throats on swallowing due to the mixture of air with the food in the sac and that these unpleasant noises stimulated so much curiosity on the part of their companions that the patients found it embarrassing.

Attacks of coughing, choking or strangling occurred in twenty-eight of the fifty-three patients. They occurred particularly when the patients were lying down, and several patients complained that they were frequently awakened at night by choking attacks. The attacks undoubtedly occurred when the contents of the sac spilled over into the lumen. Two patients with pulsion esophageal diverticulum had pulmonary abscess from aspiration of the contents of the diverticular sac while sleeping and required drainage of the abscess before the diverticulum could be operated on. Several patients have sought operative relief because of choking attacks and the danger of a pulmonary abscess due to aspiration must always be appreciated in such cases.

When my co-workers and I at the Lahey Clinic first began to operate on patients with esophageal diverticulum, many of the patients came with a very large diverticular sac and were therefore unable to get food past the sac into the stomach. In spite of the fact that the practical absence of mortality¹ now attracts patients to earlier operation patients still appear with large sacs (fig 3) and symptoms of obstruction. While persons who deal with diverticula regularly are entirely familiar with the mechanism of this obstruction, many are unfamiliar with the causes and so unaware of the danger in the presence of these sacs in the use of the bougie and in any procedure but the most careful esophagoscopy.

Figure 8 (A, B and C) shows better than can any descriptive words how the downward traction of the sac on its neck brings the opening into the sac into a transverse position and converts the true opening into the esophagus into a lateral position and how downward traction made by the food-filled sac brings the two lips of the true opening into the esophagus together so that in patients with a large diverticulum this opening is converted into a mere lateral slit. In some cases

it is difficult if not impossible to find the opening and pass a tube into the stomach for preliminary feeding purposes, even after careful search for the opening through the esophagoscope.

In two cases in which we operated for this type of diverticulum the sac had been perforated before the patient came to us, in one case by a bougie and in the other by an esophagoscope. In the two cases nearly fatal mediastinitis resulted, requiring prolonged mediastinal drainage and in one case a temporary gastrostomy. A realization of the altered relationship between the opening into the diverticulum and the opening into the true esophagus will protect any one against a repetition of such perforation.

The successful operative treatment of esophageal pulsion diverticulum involves the complete removal of the sac and its neck, the complete removal of the constrictor muscle fibers from about the neck of the sac and the protection of the patient from the development of cellulitis between the prevertebral and pretracheal fascia and extension of this infection into the

1 There has been but one death in the eighty-two cases in which operation was done and that was in a man of 85 who had a diverticular sac in his mediastinum the size of a small grapefruit. Death was not related to the diverticulum itself but was due to uremia. He would not have died however had he not been operated on and the death is properly attributed to the operation.

mediastinum There are and perhaps always will be two plans of removing pulsion diverticula surgically In one the operation is completed in one stage In the other the sac is completely freed from the muscle fibers about its neck and implanted in the wound, to be left for from ten to fourteen days, and a gauze drain placed in the mediastinum from which it has been

Fig 4—A typical traction diverticulum This type of diverticulum being the result of traction rarely points downward possesses all the muscular coat of the esophagus and so tends to empty itself readily It is dealt with quite satisfactorily by dilation

removed At the end of this time the mediastinum is so walled off by exudate that mediastinitis cannot occur, and the fascia planes in the neck are so closed that cervical cellulitis cannot occur

Both methods have proved their worth in a large experience in several men's hands We have consistently adhered to and further developed the two stage procedure because we have had such a low mortality with it

and because it gives us such a feeling of comfort and security to realize that with it the dangers of deep cervical cellulitis and mediastinitis are eliminated We recognize the results obtained by the advocates of the one stage operative plan and in no way wish to detract from its merits We cannot, however, bring ourselves to trust to a suture line in the esophagus or ligature of the neck of the diverticular sac, when the mediastinum has been and still is widely open, without walling off exudate and protective granulations We are conscious of the fact that if leakage at the suture line or at the point of ligature of the sac's neck occurs, contaminated esophageal contents will gravitate into the mediastinum and mediastinitis result Perhaps a relatively large experience with mediastinitis in patients with large intrathoracic goiters has given us too grave an impression of the seriousness of this

Fig 5—An unusual type of diverticulum It is intrapleural and located just above the diaphragm It distresses the patient because food accumulates in it decays and is disturbing to both his taste and his breath The operative management involves a serious problem The sac must be approached through the pleura If one amputates the sac at its neck there is always the serious menace of leakage from the esophagus with infection the formation of an esophageal fistula and possible death The plan developed and employed by me is diagrammatically illustrated in figure 6

lesion and the lack of one's ability to institute measures which have any great value in checking its progress should it occur

Not as an argument against the one stage operation for esophageal diverticulum but rather as an explanation of why we prefer and adhere to the two stage plan, we have said that if we were to operate successfully by the one stage plan in a hundred cases of esophageal pulsion diverticulum but in the hundred and first a leak occurred, mediastinitis developed, and the patient died, we would feel that the other hundred operations would better have been done in two stages and the patients so successfully protected against mediastinitis that the hundred and first would not have died In our entire experience with esophageal diverticulum we have not seen any degree of mediastinal infection

We have never felt that it was necessary to pass an esophagoscope into the sac of the diverticulum We recognize that this procedure is advocated by some and we recognize that in other hands it may be useful We have always, with cervical block anesthesia induced by procaine hydrochloride, been able to dissect the sac completely without this aid With this type of anesthesia, patients can be asked during the operation to swallow, if necessary and the sac can be distended and visualized without difficulty

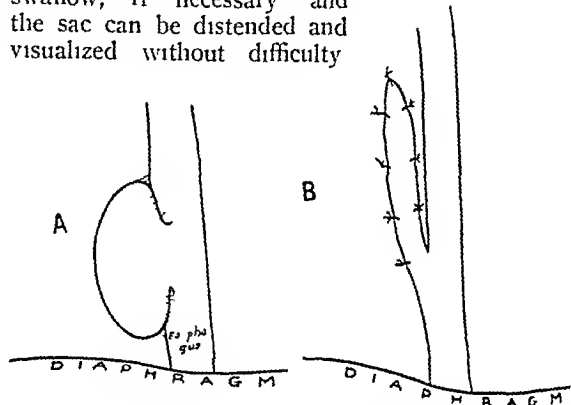

Fig 6—A shows the outline of the diverticulum as it was found at the operation The sac was completely dissected so that it hung entirely by its neck It was then picked up at its outer surface and so carried upward beside the esophagus that it was converted into a tube In order to approach the sac I asked Dr R H Overholt of the department of thoracic surgery to remove long sections of rib over this side of the chest insert rib spreaders collapse the lower lobe of the lung and expose the esophagus The unopened sac was then sutured with black silk sutures to the posterior gutter of parietal pleura beside the esophagus (B) As a result of this implantation of the unopened sac in an upward direction parallel with the esophagus no further bismuth entered the sac and the symptoms due to the diverticulum were entirely relieved This method of taking care of the sac without amputating it proved to be quite satisfactory It is but proper to state in describing the successful outcome of this operation that as a result of collapse of the right lung, even though it was frequently inflated by the anesthetist gangrene of the collapsed right lower lobe occurred The condition was successfully managed by lobectomy done by Dr Overholt

There are undoubtedly different ways of operating for diverticulum, and the type of operation must be settled according to one's personal convictions of the risks involved and the results obtained

While it is not the purpose of this paper to deal with operative details, two measures which I have described in the two stage operation deserve mentioning One is the plan of implanting the sac of the diverticulum in the wound between the first and the second stage of the operation so that it points upward (fig 8 D) and food cannot enter the sac and swallowing is immediately unobstructed The other is the method of burying small diverticular sacs in the wound by attaching the tip of the sac to the upper edge of the thyroid muscles by two black silk sutures as shown in figure 8 D This makes it possible to do two stage operations on any diverticulum no matter how small if it has a sac and, by the employment of the black silk stitches, to find readily the tip of it

sac in the granulating wound when it is reopened at the second operation

In Dr Hoover's follow-up studies of the fifty-three patients operated on over two years ago, it is evident that many of the patients who have had no postoperative dilation have had excellent results. We believe, nevertheless, that postoperative dilation regardless of

Fig 7—The esophagus after the administration of a thin bismuth mixture after the operation had been completed. The outline of the upward implanted sac is shown in dots. A small amount of bismuth entered the neck of the sac although no bismuth is seen ascending into the body of the sac itself.

softened will be worth while. In our cases, wide postoperative dilation with a modified Plummer bag has definitely made our end results more satisfactory.

The complications of this operation are for the most part produced at the time of the operation. Whether the sac is removed by a one or a two stage operative plan, since the approach to the sac is directly behind the thyroid and the neck of the sac is at the pharyngo-esophageal junction, where the recurrent laryngeal nerve enters the larynx, that nerve will always be endangered. Five cases of unilateral recurrent laryngeal paralysis have occurred. In four the paralysis proved to be but temporary and in only one has it been permanent. The relationship of the laryngeal nerve to the neck of the sac must be realized, and the nerve must be carefully protected from injury.

Since it is our custom, when the sac is cut off at its neck in the second stage of our operation, not to close the opening into the esophagus but to place a small gauze pack over it for a few days and then permit it to granulate up from the bottom, it is not surprising that in the early cases there were eighteen temporary fistulas. Of these, eight were free from leakage in three weeks, and of the remaining ten, five healed in less than eight weeks. In the five cases in which the fistula did not heal in this time a third operation was done to remove the fistulous tract or a remaining amount of mucous membrane at the neck of the sac, which had been inadequately removed at the first operation. Since we have developed the plan of implanting the sac high in the neck so that it points upward little trouble with fistulas now results.

A secondary abscess developed in the wound in five cases, all ruptured themselves or were drained and healed without further complications.

Difficulty in swallowing developed between the first and the second stage in some cases in which the diverticular sac was very large. It was caused by swallowed

air that accumulated in the large sac implanted on the skin (fig 7) and so distended the sac that it pulled on and obstructed the longitudinal esophagus. This distention by air of the large sac implanted on the skin can so dilate the sac that its walls become gangrenous. The condition is immediately remedied by suturing a catheter into the dome of the distended sac with a purse string suture. By means of this procedure, done two or three days after the first stage operation, the catheter being guided by the finger in the sac into the esophagus, gastrostomy for preliminary feeding will only rarely be necessary, since feeding through the tube can be carried out.

Two patients have had a complete recurrence of the sac, as a result, we believe, of an inadequate primary removal of the sac. One of them has been reoperated on, with complete relief. The other has so far refused reoperation. Two patients have had partial recurrence, with some symptoms. One had been unsuccessfully operated on elsewhere, and a second two stage operation was done by us. Nineteen patients showed by x-ray examination some retention of bismuth in the hypopharynx, but eleven of these were free from any symptoms whatever.

In two cases the second stage of the operation was not done. A death, the only one in the entire series, resulted from uremia and suppression of urine. In this case there was no local or pulmonary reaction after the operation, and the death was related to the operative procedures only in respect to the fact that the patient would not have had the suppression of urine and uremia if he had not been submitted to an operative procedure. In the second case in which, because

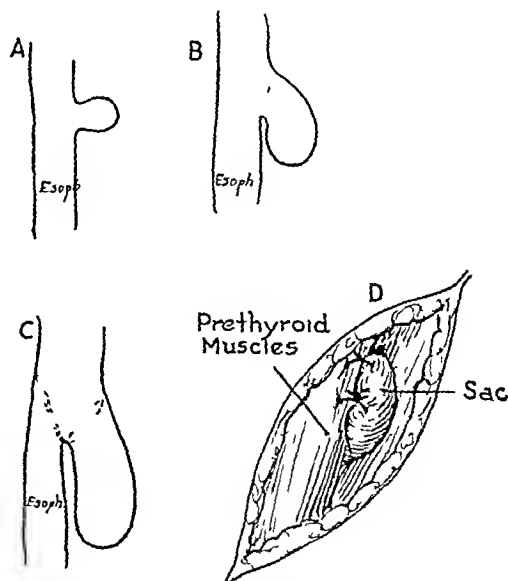

Fig 8—A, B and C demonstrate how the opening into the sac changes position as the sac enlarges. In the early sac the opening is directly lateral as in A, as the sac becomes larger and descends it becomes a little more oblique as in B, and as the sac becomes still larger and descends into the mediastinum as in C, the opening into the sac and the previous transverse opening into the esophagus become oblique. By the traction of the food-filled sac the edges of the opening into the true esophagus are brought together so that the opening appears as a mere slit. D shows the method of suturing the sac with black silk stitches to the outer and upper edge of the sternohyoid muscle and also the plan of implanting the sac in the upward direction so that between the first and the second stage food will not pass through it.

of the patient's weakened state the sac was not removed at a second stage operation but was dissected free and left implanted high in the wound, there has been complete relief of all symptoms. We have always

been of the impression that if the sac were completely freed and sutured so high in the neck that food did not enter into it there would be complete relief of symptoms. This patient has now been over three years without a return of symptoms and we believe that in the very old and in bad risks, such as he was, the procedure followed is sensible and justifiable.

SUMMARY

The end results in fifty-three cases of pulsion esophageal diverticulum were as follows: failure two, poor results two and good results forty-nine.

An unusually large supradiaphragmatic esophageal diverticulum was successfully operated on.

605 Commonwealth Avenue

ABSTRACT OF DISCUSSION

DR STUART W. HARRINGTON, Rochester, Minn. While a diverticulum may be present in any part of the esophagus, it more commonly occurs in the upper portion at the junction of the esophagus and the pharynx. Diverticula in this location are most commonly of the pulsion type. Their location is fairly constant in the posterior wall of the pharynx at the level of the cricoid cartilage in an area of muscular deficiency. Such diverticula are essentially herniations of the inner layers of the esophagus through the muscular layers, and the only treatment that effects relief of symptoms is complete surgical removal of the sac. The operative treatment of pharyngo-esophageal diverticulum may be carried out in one or two stages. The one-stage operation is more applicable to small diverticula, principally those in which there is a fairly definite neck to the sac. The indications for this operation are much less frequent than for the two stage operation. Of the 227 patients with pharyngo-esophageal diverticulum who were operated on at the Mayo Clinic from Jan. 1, 1908, to Jan. 1, 1937, forty-seven underwent the one stage operation and 180 the two stage operation. In the one stage operation the sac is ligated at its junction with the esophagus and the stump is either inverted or plicated into the wall of the esophagus, care being taken that the sac is removed completely. I believe that the possibility of recurrence following the one stage operation is less than that for the two stage operation because the true neck of the sac can be visualized and more accurately removed at the original operation. In the two stage operation the sac is dissected from the surrounding structures and brought outside the wound. The neck of the sac is sutured to the underlying muscle and skin at the upper angle of the wound. Care should be taken to turn the neck of the sac upward in order that it can drain and also be more readily identified and accurately removed at the second stage of the operation. In cases in which the neck of the diverticulum is large and it is difficult to identify the true junction with the esophagus I have found it helpful to place a loose silk suture round the neck of the sac at its junction with the esophagus as a landmark to facilitate its identification at the second operation. The sac is completely removed in the second stage of the operation, which is usually done within six to eight days after the first stage. The two stage operation is usually done for large diverticula, particularly those that extend into the mediastinum and in cases in which there is considerable inflammatory reaction around the sac.

DR THOMAS A. SHALLOW, Philadelphia. Dr. Lahey has emphasized the value of the two stage procedure for the removal of pharyngeal diverticula solely on its safety, owing to the prevention of mediastinitis. There is no question that mediastinitis did follow the old operative procedure not because the procedure was wrong but because it had not been perfected. Not until the work of Jamison in conjunction with Lord Moynihan in 1927 did we obtain our first accurate anatomic knowledge of the site of origin of pharyngeal diverticula. With this information all procedures except the one stage combined method of surgical removal were abandoned. The principles on which this procedure is based are as follows: (1) to leave the pharynx and esophagus in normal anatomic relationship; (2) to repair the hernia—not only the hernial sac but the

pharynx through which defect the herniation occurs, (3) to do this without leakage and as a primary procedure. Normal anatomic position and physiologic function can be secured or with the aid of the esophagoscope. No surgeon is so sure of himself in the removal of the mucous and submucous as even in a one stage procedure, that he can disregard the value of modern medical contributions, in this instance the esophagoscope. With the esophagoscope in position after the sac is identified, it is impossible to produce constriction or distortion of the pharynx or the esophagus when removing the sac and repairing the pharyngeal musculature. The third principle, failure of leakage and prevention of mediastinitis, rests solely in the hands of the surgeons. In contrast, the advocates of the two stage procedure do not leave the esophagus and pharynx in their normal relationship because secondary dilation is almost universally required. The patient is subjected to two operative procedures instead of one. Dr. Lahey removes the musculature around the neck of the sac. In the one stage procedure the musculature is used for repairing the defect in the pharyngeal wall. No attempt is made to repair the pharynx, but since one is dealing with a hernia of this structure, repair is the first principle of the cure. My experience is based on ninety-nine cases of repair of pharyngeal diverticula by the one stage procedure with four deaths—two from uremia, one from rupture of the lung when I was using the intratracheal apparatus and one from coronary disease occurring on the sixteenth day. In none of these cases were there any evidences of mediastinitis.

DR W. WAYNE BARCOCK, Philadelphia. The only advantage that has been claimed for the two stage operation for esophageal diverticulum over the single stage procedure is a lessened risk of mediastinitis. The modern one stage operation has a much shorter period of disability, much less discomfort, and restores normal swallowing function without stricture or the need of the dangerous secondary bougienage. It eliminates the open infected wound of the two stage operation and was followed by primary union and a nearly invisible scar in 94 per cent of our cases. As I have never seen mediastinitis follow, I think the one stage method the safer procedure. Since 1930, sixty-five patients with esophageal pouches have been admitted to the Chevalier Jackson Bronchoscopic Clinic at Temple University. Nineteen patients, mostly with small sacs and milder symptoms were referred to their home surgeons. Forty-six, from 30 to 89 years of age, remained for the one stage operation. The bronchoscopic assistance devised by Dr. Jackson enabled a cleaner operative field, aided an accurate water and air tight closure of the esophagus with suture and ensured an esophagus of uniform caliber without stricture. Of the patients 70 per cent were males, forty-two had dysphagia and eructations from one week to fifteen years, twenty-two cough and secretion, twenty gurgling, four fulness in neck. The sac was small in sixteen of medium size in eleven, and large in twenty-five. With the patient under local anesthesia, light tribromethanol amnesia being employed, a transverse incision was used without division of any important vessel or muscle. A minute split tube drain was left for the first forty-eight hours. Normal swallowing function was proved before patients were discharged by barium sulfate and x-ray study. There has been no recurrence, no stricture, no secondary bougienage, no mediastinitis. Two had temporary left recurrent palsy. One had a previous unsuccessful anchorage operation. Over one-half left the hospital healed and with normal swallowing function in from ten to sixteen days. The only death was from a coronary accident in a cyanotic cardiopathy of 83 years. In other words, there was no death due directly to the operation. Dilation of the esophagus so often required after the two stage operation is a not uncommon cause of mediastinitis, but suppurative mediastinitis is not invariably fatal. Of seven cases of mediastinitis following various lesions of the esophagus we were able to save six by a simple method of drainage through the neck. I feel that the danger of mediastinitis from the improved one stage operation for esophageal diverticulum has been much exaggerated.

DR FRANK H. LAHEY, Boston. I very much appreciate the discussions by Drs. Harrington, Shallow and Barcock. I am always perfectly certain that a discussion as to whether one should operate on a patient by a one stage or a two stage procedure will get a little hot and it is a very good thing.

is one of the ways by which all the facts are brought out and presented. When we have finished we shall all I believe select our methods as I have stated in the paper based on our own impressions and our own experiences. Of course it is easy for us to pick up an argument to support our own method as opposed to another, that applies to me, and it applies to those who advocate the one stage procedure. As to the question of the dangers of postoperative dilation there have been no fatalities no complications at all from dilation. It is unfair to apply these two cases with preoperative mediastinitis to the operative risk, because both patients had preoperative mediastinitis literally months before they came to us for operation. Their problem was not in our hands, as these accidents occurred elsewhere than in the clinic. One required a posterior rib resection and a posterior approach to the mediastinum the other required gastrostomy and prolonged drainage from the mediastinum. Both came within an ace of dying. As to Dr. Shallow's argument you must allow me a little shot back at him. He says that if it were so that one could not depend on primary sutures we would not have gastric resections and we would not have colon resections. From my point of view one should not have primary colon resections. We gave up primary colon resections years ago because the mortality was so high. We haven't done it for eight years. They are all done in two stages and the danger of peritonitis is entirely eliminated. He says that if we go on with two stage operations in this way we are in the horse and buggy age and that if we continued this way we wouldn't be flying around in airplanes the way we are. Well it is my opinion particularly as relates to one stage operations that as the result of them a lot of these people are flying around but they aren't flying around in airplanes.

RELAPSING FEBRILE NODULAR NON-SUPPURATIVE PANNICULITIS

(WEBER-CHRISTIAN DISEASE)

RICHARD J. BAILEY, M.D.

Fellow in Dermatology and Syphilology, the Mayo Foundation
ROCHESTER, MINN.

In 1925, under the title "relapsing nonsuppurative nodular panniculitis" Weber¹ described an unusual clinical syndrome which was characterized by crops of subcutaneous nodules occurring during febrile periods and which on histopathologic examination was found to be accompanied by a particular type of fat atrophy. He felt that the syndrome was similar to that described by Pfeiffer² in 1892 and by Gilchrist and Ketron³ in 1916. More recently additional cases have been reported,⁴ and Christian,⁵ in one of these, properly modified the title by the addition of the word febrile.

My interest in this condition was stimulated primarily by its unusual severity in the first of the following five cases, which were seen at the Mayo Clinic. Because of the unusual features of this case the report is given in detail, in the other cases the reports are summarized.

Read before the Section on Dermatology and Syphilology at the Eighty-Eighth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1937.

REPORT OF CASES

CASE 1—A single woman aged 24 was admitted to the hospital July 28, 1934 complaining of fever, malaise and persistent subcutaneous nodules of four months' duration. There was no history of tuberculosis in the immediate family. The patient had enjoyed excellent health with the exception of bilateral otitis media in childhood and an attack of influenza in 1926. Early in April 1934 a slightly tender subcutaneous nodule was noted on the left upper part of the abdomen. There were no other subjective signs at the time but two weeks later because of slight malaise she consulted a physician who found that her temperature was 102 F and that other similar nodules were present on the thigh and shoulder. There was slight erythema over the original lesion which had increased to about 8 cm. in diameter but there was no noticeable change on the skin over the other nodules. Since that time there had been episodes of fever the temperature varying from 102 to 104 F and new nodules appeared all of which had apparently persisted until the time of her admission. In this interval the patient had lost 20 pounds (9 Kg.). She received much medication possibly including iodides during this time, and prior to the onset of her difficulty she remembered having occasionally taken a proprietary cold-laxative tablet.

Although the patient's temperature was 102 F on admission she did not appear acutely ill. She weighed 179 pounds (81 Kg.) and aside from the cutaneous condition general physical examination gave essentially negative results. The heart and lungs were apparently normal and the liver and spleen were not palpable. The tonsils were enlarged and pus could be expressed from the crypts. The systolic blood pressure in millimeters of mercury was 120, the diastolic 82. There was evidence of secondary anemia in the estimation of hemoglobin as 54.6 per cent erythrocytes numbered 3,970,000 and leukocytes 5,100 per cubic millimeter of blood. Other laboratory examinations including urinalysis, Kahn, Kline, Hinton and Kolmer Wassermann tests of the blood, studies of liver function, and agglutination tests for *Bacillus typhosus*, *B. paratyphosus*, *B. tularensis* and *B. abortus* showed no abnormality. Tuberculin tests by the Mantoux method and with purified protein derivatives were negative. Roentgenologic study of the thorax showed slight elevation of the diaphragm on the left and a roentgenogram of the teeth elicited two areas of periapical infection.

On examination of the skin approximately thirty subcutaneous nodules varying from 1 to 12 cm. in diameter were palpable on the abdomen, upper part of the back, shoulders, arms, lumbar region and thighs; these occurred singly and in groups. The skin overlying the nodules was unchanged where small deep lying nodules occurred. Two of the larger lesions were apparently firmly fixed to the skin which was slightly depressed, bluish red, brown on palpation and moderately pigmented (fig. 1). Others showed varying degrees of diffuse or mottled erythema. Local heat and tenderness on pressure varied considerably but none of the lesions were distinctly painful. The outer right thigh showed some diffuse irregular depression and was smaller than the left. There seemed to be no tendency toward suppuration.

The patient was hospitalized for 115 days. During this period her temperature rose each afternoon to between 101 and 105 F and usually did not fall below 100 during the twenty-four hours. The sedimentation index varied from 169 to 174. Hemoglobin ranged from 42 to 65 per cent erythrocytes from 2,780,000 to 3,970,000 and leukocytes from 3,100 to 8,300 per cubic millimeter of blood. No significant manifestations were reported on examination of the blood smears. A few days after admission bilateral otitis media developed which responded to local treatment. The following procedures were performed at various times during this period with no apparent beneficial effect: four transfusions each of 250 cc. of blood; twelve intravenous injections of neocarspharmine; two injections of gold sodium thiosulfate intravenously; and two intravenous injections of gentian violet. Salivgram and whole milk were given once each. Ferric citrate and viosterol were administered over extended periods. Filtered roentgen rays were applied over the affected areas on two occasions. New crops of nodules appeared from time to time and there was

considerable edema present in one arm and leg when the patient was dismissed. Ten blood cultures were reported negative.

An early, deep lesion was removed from the abdomen on August 3, and direct smears made from it were negative for evidence of Hansen's and tubercle bacilli. Direct cultures showed no growth and two animal inoculations gave negative results. On histopathologic examination of a section from

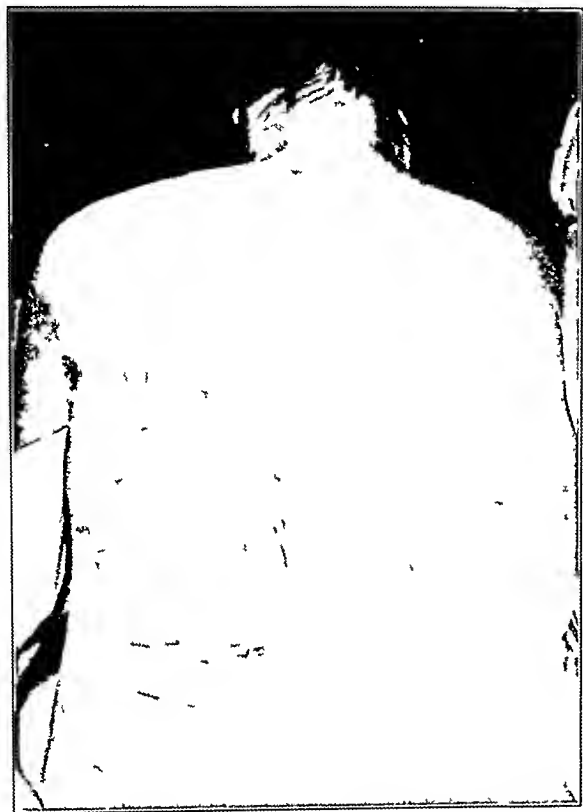

Fig 1 (case 1).—Multiple subcutaneous nodules on the back showing little visible change except slight erythema and depression.

the lesion, the cutis showed edema and a moderate perivascular infiltrate but otherwise was normal (fig 2). There was edema and necrosis of the fat tissue and edema of the connective tissue between the fat lobules. A focal infiltrate of lymphocytes, round cells, plasma cells, endothelial cells, polymorphonuclear leukocytes and macrophages was present between the fat cells and in the connective tissue septums. The blood vessels showed periarteritis organization and proliferation of the intimal lining in varying degree. The sudan III stain showed stellate and spindle connective tissue cells and polyblast macrophages (round) filled with fat droplets. Fat droplets were seen lying free owing to the disintegration of the fat cells. Macrophages could be seen invading the fat cells and in two areas there were atypical giant cells. A second more superficial nodule was removed from the chest on October 4 and this on histopathologic examination showed changes similar to those just mentioned which was consistent with the diagnosis of panniculitis (Weber). There was no evidence of tuberculosis. The patient returned to her home on November 19 and the process continued essentially the same until her death on June 11, 1935. Permission for necropsy was refused.

CASE 2.—In September 1934 a married woman aged 43 was referred to the Section on Dermatology because of a history of recurrent subcutaneous nodules occurring on the trunk and extremities and associated with chilly sensations and malaise of about four months duration. Her previous history was pertinent only in that she had taken an iodine medication daily for about the same period having had a stroke during the previous year.

The blood pressure reading of 225 systolic and 160 diastolic with the concomitant observations suggested a diffuse arterial

disease. Purulent material was expressed from the tonsils and there was roentgenologic evidence of periapical infection of several teeth. Physical and roentgenologic examinations of the thorax gave negative results. The value for hemoglobin was 69 per cent, and there were 4,630,000 erythrocytes and 6,900 leukocytes per cubic millimeter. The Kline and Kahn tests of the blood were negative. The temperature was 99.4 F. Palpable nodules, varying from about 0.25 to 2.5 cm. in diameter were found on the back, shoulders, breasts, buttocks and thighs. None of these areas showed more than a slight erythema and there was no pain except on firm pressure. A lesion was removed from the right thigh for biopsy and Dr. Montgomery reported early changes suggestive of relapsing febrile nodular non-suppurative panniculitis.

No new lesions were evident on examination after a lapse of one year, but in a letter a short time later the patient mentioned the appearance of a number of new nodules on resumption of an iodine-containing medication; these disappeared when the medication was discontinued. In a subsequent letter, received in October 1936, no mention was made of any recurrence.

CASE 3.—On the occasion of a previous visit to the clinic in 1921, a married woman, aged 56, was apparently in good health except for evidence of infection of the teeth and tonsils. On her return in October 1935 she stated that in December 1934 she had been ill with fever and "muscular" pains of one week's duration; this had been accompanied by slightly painful nodules on the upper part of the thighs. There was gradual recovery, and then a brief relapse. A short time before her last admission she had noted a return of symptoms. She had occasionally taken a medication containing bromides since 1921.

General examination, with the exception of the cutaneous changes and roentgenologic evidence of a poorly functioning

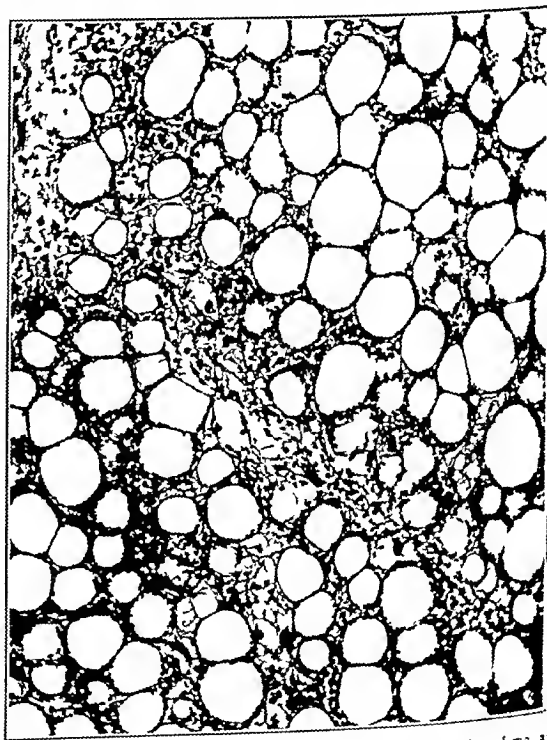

Fig 2 (case 1).—Subcutaneous fat showing diffuse slight edema and necrosis and infiltration with phagocytic cells of foamy appearance (X 100).

gallbladder with stones gave negative results. There was a definite depression with erythema and slight pigmentation over several subcutaneous firm tender nodules from 3 to 6 cm. in diameter which were present on both thighs, the right leg and the abdomen (fig 3). Biopsy of a lesion on the abdomen was reported as typical of Weber-Christian disease. There was little change in the cutis with lymphocytes, plasma cells and phagocytes invading the subcutaneous fat; there were rare

large nucleated cells with foamy cytoplasm in glandlike arrangement and some increase in the connective tissue and occasional cells with multiple nuclei. Some of the larger blood vessels were obliterated. One culture of the blood was reported negative.

While the patient was under observation a small nodule appeared on the right thigh and the temperature became elevated for two days to 102 F. November 22 after she apparently had been free from fever or activity of the lesions there was a recurrence of similar nodules with an elevation in temperature to 102 F. She stated that her only medication had been an antirheumatic remedy which contained potassium iodide. The patient has not replied to recent letters of inquiry regarding further recurrences.

CASE 4—In February 1920 a man aged 38 was examined at the clinic because of recurrent attacks of red subcutaneous nodules of four years' duration. He had suffered from attacks of tonsillitis and rheumatism since the age of 6 years when torticollis had developed. His tonsils and teeth had been removed without any effect on the recurrence of the nodules. These attacks were not seasonal and the lesions appeared on

with slight perivascular infiltration (figs 4 and 5). In the subcutaneous portion the fat lobules showed diffuse changes, consisting mainly of large cells with foamy cytoplasm and many containing several large nuclei interspersed between the fat cells. In places there were varying numbers of polymorphonuclear cells, plasma cells, lymphocytes, endothelial cells and fibroblasts. No typical Langhans or Touton giant cells were seen. The connective tissue septums were little

Fig 3 (case 3)—Flattened area on left thigh and distinctly depressed areas on right thigh at the sites of involuting lesions.

the arms, legs and thighs. Fever had accompanied their onset on at least two occasions. The patient was extremely nervous and admitted drinking large quantities of alcohol daily. He had taken many proprietary nerve tonics, daily doses of an effervescent bromide remedy and varying quantities of paregoric. He denied the hypodermic use of opium derivatives.

The patient was obese and weighed 210 pounds (95 Kg). His temperature was normal and he appeared to be in good health. The blood pressure in millimeters of mercury was 170 systolic and 118 diastolic but examination otherwise with the exception of the cutaneous complaint gave negative results. A Wassermann test of the blood was negative. Blood cultures resulted in no bacterial growth. About ten subcutaneous nodules from 1 to 3 cm in diameter, were palpable on the back of the arms, thighs and legs, some showing slight erythema. There were no evident scars characteristic of hypodermic injections or resulting from suppuration. Definite depressed and flattened areas were present presumably at the sites of former lesions. Small typical psoriatic plaques were present over the elbows and knees.

A nodule was removed from the left thigh for biopsy. Examination revealed a few dilated blood vessels in the cutis

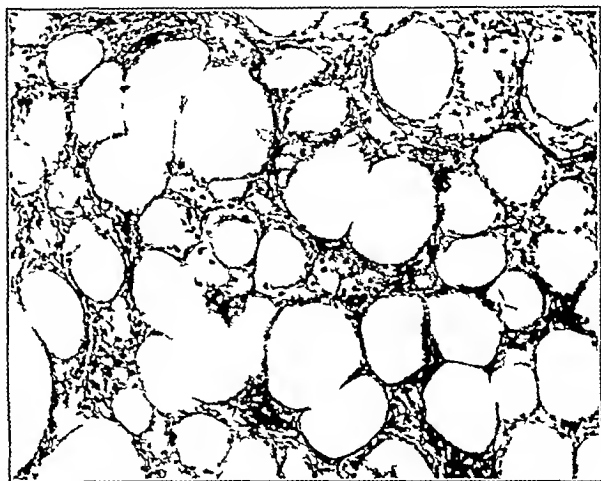

Fig 4 (case 4)—Subcutaneous fat showing large numbers of phagocytic cells and the relatively small degree of fibrosis slightly reduced from a photomicrograph with a magnification of 100 diameters.

changed and although there were occasional obliterated vessels lying within them the blood vessels as a whole showed little change. The histopathologic diagnosis was deferred.

Nodular syphilis, erythema induratum, erythema nodosum and a migratory phlebitis were considered as possible diagnoses, and the patient was given seven intravenous injections of arsphenamine as a combined provocative and therapeutic test. The Wassermann test remained negative. During this period there was an exacerbation on two occasions, with a slight elevation in temperature. The patient was then dismissed for institutional care for alcohol and drug addiction. Until 1925 when per-

Fig 5 (case 4)—Subcutaneous fat. Higher magnification showing the glandlike arrangement and foamy cytoplasm of the phagocytic cells slightly reduced from a photomicrograph with a magnification of 490 diameters.

manent institutional care was advised the patient was examined five times each visit being prompted by a return of the nodules. The highest temperature recorded was 100.2 F. General examination was essentially negative each time. On the occasion of his last visit both the spinal fluid examination and Wassermann test of the blood were negative and a trial with a combination of neoarsphenamine coagulen (Ciba) and a stock

streptococcus vaccine had no appreciable effect. No information regarding this patient after that time could be obtained.

CASE 5—A married woman, aged 45, entered the clinic in March 1920 complaining of recurrent attacks of nodules at various times without seasonal relationship during a period of five years. Her history otherwise was unimportant. The attacks were ushered in by chills and fever, and from one to

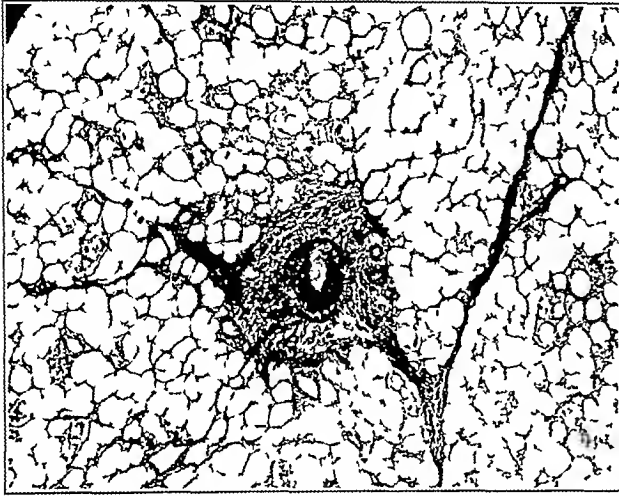

Fig. 6 (case 5)—Subcutaneous fat showing fibrosis around a large blood vessel. The intralobular fibrous septa show little change. The diffuse changes in the fat lobule consist mainly of invasion of phagocytic cells. Slightly reduced from a photomicrograph with a magnification of 33 diameters.

twelve nodules would appear within a week on the trunk or extremities. No accurate history was obtained regarding previous medication.

The patient was slightly obese and weighed 140 pounds (63.5 Kg.). General examination with the exception of infected tonsils and teeth and the condition of the skin gave essentially negative results. A roentgenogram of the thorax, urinalysis, the Wassermann test, routine blood counts, a blood culture and a Pirquet tuberculin test were all negative. Examination of the skin revealed deep nodules up to 3 cm. in diameter on the right arm near the elbow and on the thighs. A few depressed, slightly cyanotic and pigmented depressions were noted on the trunk. Slight erythema was present over the nodules, but they were not painful.

A nodule was removed from the thigh for biopsy (figs. 6 and 7) and there were three opinions regarding the histopathologic observations, namely subdermal inflammation, a questionable small abscess deep in the subcutaneous fat and atypical erythema nodosum. The diffuse changes occurring around a sclerosed blood vessel are shown in figure 6.

No further nodules appeared on observation over the next six weeks, during which time six intravenous injections of neoarsphenamine were given and the tonsils and infected teeth were removed. One month after returning home however the patient had a marked recurrence of the condition with fever of one week's duration, and she had to be hospitalized. Her home physician gave her a prescription containing potassium iodide which she used for four months. During this period she stated that there had been repeated new crops of nodules. On her return to the clinic late in November her temperature was 99.8 F. and there were new nodules on the thighs, legs and upper part of the left arm. These receded slightly during the next week. When questioned recently the patient did not recall having had any attacks after 1930 but stated that a depressed area remained on one thigh.

REVIEW OF THE LITERATURE

Of the eight patients whose cases are reported in the literature (summarized in the accompanying table), six were adult women, one was a girl of 8 years, and one was a man of 53. There seemed to be nothing pertinent to the condition in the personal or family history or in the results of a general examination. Evident foci of infec-

tion of the teeth or tonsils were present in three cases (3, 5 and 8), two patients had syphilis (1 and 7). The nodules themselves varied in size from 0.5 to 9 cm. in diameter, showed no tendency to suppuration and appeared most frequently on the thighs although they were found also on the trunk and arms. The attack varied in duration from one month to fifteen years; they occurred at irregular intervals of weeks to years without apparent relationship to season. Varying degrees of fever and malaise usually were present with the attack, the most severe degree being reported in Christian's case. Depending apparently on the depth of the nodule, varying degrees of erythema were noted on the overlying skin. On involution, definite depression of the previously involved sites was of special note in five cases (1, 2, 4, 5 and 6), and Christian tabulated this as one of the clinical criteria for diagnosis. Weber felt that the previous ingestion of drugs, particularly iodide and bromides, might be considered one of the etiologic factors and presented one case in illustration. With the possible exception of one case (5), in which there was a possible flare up of the condition after a tuberculin test, the question of tuberculosis as an etiologic factor did not seem pertinent. Agglutination tests for undulant fever were made in three cases (4, 5 and 8) and were negative; cultures of the blood and of the nodule itself were likewise negative in these cases.

Histologic descriptions and illustrations show only minor variations. The report of Christian may well be taken as an example.

In places edema and necrosis of the fat tissue, edema of the connective tissue between fat lobules, and a local inflammation between the fat cells and in the connective septa of lymphoid cells, plasma cells, young connective tissue cells, endothelial cells, phagocytic for fat droplets, a few polymorphonuclear leukocytes and a rare foreign body giant cell so that the subcutaneous tissue thus was infiltrated. Fatty acid crystals were not present. Blood vessels as a rule were

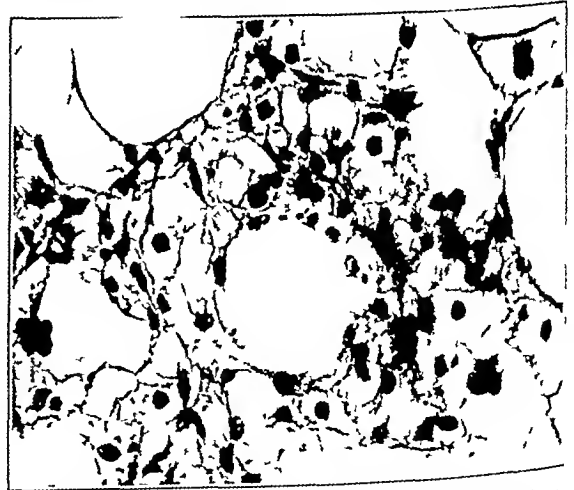

Fig. 7 (case 5)—Subcutaneous fat. Higher magnification of a foamy cell with multiple nuclei, somewhat resembling a giant cell. The cell is surrounded by other cells, some of which are slightly reduced from a photomicrograph with a magnification of 66 diameters.

normal. A few showed periarthritis, rarely one showed endarteritis with proliferation of the endothelial cells. The inflammatory process did not extend to the dermis and the skin itself was not scarred.

Emphasis is placed particularly on the large cell with foamy cytoplasm arranged in glandlike manner between and around fat cells, variously described as macrophages and histiocytes accompanied by multinucleated giant cells by Weber, Gilchrist, Kelton, Mohr,

and Way, diffuse fibrosis by Pfeifer and Weber and fibrosis as a terminal stage by Alderson and Way. Brill however, described a nodule of long duration which did not show fibrosis.

COMMENT

The five cases of relapsing febrile nodular nonsuppurative panniculitis I have described agree in essential clinical and histopathologic characteristics with the eight cases reported in the literature. Case 1 demonstrates the severe character which may occasionally be manifested by this syndrome, indicating the possibility of a protracted course without remission. Christian's case was the most severe of those previously reported and it may be seen that a particular similarity exists also on histopathologic examination in the degree of diffuse necrosis present, the few giant cells and the small degree of fibrosis. All five of the patients had obvious infec-

Among these, erythema nodosum will be considered first. The shorter duration, frequent seasonal recurrences, the distribution of the nodules, usually on the lower extremities, and the definite tenderness and bruise-like color changes serve to distinguish it from the Weber-Christian type of panniculitis. Although a persistent type of erythema nodosum has been reported,⁷ it does not differ materially from the usual type except with respect to its longer duration. Giant cells have been seen in histologic sections in cases of erythema nodosum but the process is usually characterized by more infiltrate in the cutis and marked vascular changes. Erythema nodosum-like lesions have frequently been reported⁸ following the injection of several drugs particularly iodides and bromides, associated with certain diseases, and at the site of injection of bacterial antigens and vaccines. Erythema induratum in spite of its usual

Relapsing Febrile Nodular Nonsuppurative Panniculitis

Author	Age Years	Sex	Dura- tion Years	Description	Histopathologic Features
1 Pfeifer	23	♀	3	Recurrent subcutaneous nodules occurring in crops (3) of hazel nut size present over trunk and extremities showing only slight turgidity and tenderness and leaving flattened depressed areas on involution	Small cell infiltrate perivascular and between fat cells multinucleated endothelial and fat cells fibrous perivascularitis and endarteritis of small vessels
2 Gilchrist and Ketron ²	5	♀	3½	Feverish attacks (3+) accompanied by finger sized lumps under skin showing bluish tint and involving legs and thighs involution resulted in sunken areas	Clanlike foam cells some multinucleated small round cells fibroblasts plasma cells fibrosis near cutis some vessels showed proliferation of endothelium and connective tissue around them
3 Weber ¹	40	♀	1	Three prolonged attacks of fever and various sized subcutaneous swellings with overlying redness on the arms thighs and buttocks tender on palpation without bruise-like coloration	Interstitial infiltrate of polymorphonuclear leukocytes eosinophils lymphocytes and plasma cell but predominantly histiocytes phagocytic to fat some multinucleated
4 Christian ⁶	20	♀	10	Ten attacks of high fever accompanied by subcutaneous nodules up to 7 cm in diameter with out marked changes in the skin occurring on the trunk arm and legs and leaving irregular depressions	Changes in subcutis only edema and necrosis of fat tissue focal infiltrate of the septum composed of lymphoid cells plasma cells and connective tissue cells endothelial cells phagocytic for fat and a few polymorphonuclear leukocytes few blood vessels show perivascularitis and minimal endarteritis
5 Alderson and Way ⁴	41	♀	10	Numerous attacks of painful nodules on the arms thighs and legs showing dusky erythema on the skin accompanied by joint pains and fever and showing some flatness over the arms and thighs	Changes only in adipose layers nodules of giant cell lymphocytes lipophagocytes endothelial cells fibroblasts eosinophils and occasionally plasma cells perivascular infiltration
6 Matherton ⁴	46	♀	1	Recurrent attacks of pea to hazel nut sized nodules on legs dull red and painful and showing some dimpling of surface	Lipodermis normal some perivascular infiltrate dilated cells and fibrosis of the corium diffuse cellular infiltrate in subcutis of young connective tissue cells multinucleated giant cells and lymphocytes thickening of walls of blood vessels
7 Weber ⁴	53	♂	1½	Two attacks of tender subcutaneous nodules on the arms and leg accompanied by fever and apparently appearing after the ingestion of iodides	No biopsy
8 Brill ⁴	19	♀	3	Recurrent attacks (4*) of tender subcutaneous nodules involving the trunk arms and thighs pea to walnut sized with little or no changes in the overlying skin fever accompanied the attacks and definite depressed areas followed them	No change in skin patchy and diffuse cellular infiltration of subcutaneous fat with macrophages cells with foamy cytoplasm and lymphocytes no necrosis and no fibrosis no distinct changes in blood vessels

tion of the teeth and tonsils although in case 4 there were recurrences of the lesions after the removal of these foci. Also all five patients had taken bromides or iodides, and in cases 2 and 5 there was an apparent recurrence after administration of the latter medication and remission on discontinuing it.

On perusing the literature one finds little agreement as to what conditions should be considered under the general heading of panniculitis. It seems best to use this term however only in the general sense encompassing all pathologic states in which the subcutaneous fat is involved and not as synonymous with the relapsing febrile nodular nonsuppurative type. In the recent classification by Keil⁹ emphasized by the further comment of Weber, the latter is placed in a subgroup and for convenience is considered an entity. Therefore it must be differentiated from the other diseases which may involve the subcutaneous fat.

tendency to appear on the lower extremities and its protracted course and involvement of the overlying epidermis with necrosis and ulceration, may occasionally be found only in the subcutaneous fat. Usually however the degree of Wucher atrophy, the specific tubercle formation, epithelioid cells, "rosette giant cells" and the marked vascular changes distinguish it histologically.

The subcutaneous sarcoid of Darier-Roussy may offer clinical similarities, but this condition does not usually lead to the loss of subcutaneous fat and the resultant depression on involution of the lesion, and it shows histologically such characteristics as epithelioid tubercles, marked fibroblastic proliferation, perivascularitis and periphlebitis, which readily distinguish it from the

Weber-Christian type of panniculitis.¹⁰ The variation of the tuberculin test, depending on the degree of anergy present, precludes its employment in a differential capacity. In spite of the characteristic histologic appearance of the fully developed lesion in erythema induratum and sarcoid, Goeckerman¹¹ has called attention to the fact that it may be impossible to differentiate these in their early stages from other inflammatory processes. If relapsing febrile nodular nonsuppurative panniculitis, then, is to be considered akin to the three conditions just enumerated, it must demonstrate a particularly effective, early local defensive mechanism.

Another group of conditions, resulting from mechanical and chemical damage to the subcutaneous fat, however, show much more histologic similarity, although they do not necessarily compare clinically and many times can be ruled out by the history alone. These are subcutaneous fat necrosis of the new-born,¹² traumatic fat necrosis of the breast,¹³ insulin fat atrophy,¹⁴ paraffinoma,¹⁵ and the inclusive general grouping of ischemic fat necrosis,¹⁶ lipogranulomatosis,¹⁷ and oleogranuloma.¹⁸ Certain rare types of thrombophlebitis offer close clinical similarity to panniculitis of this type, and it may be necessary to look for histologic evidence of reactive inflammation of the vein and thrombosis as distinguishing characteristics.¹⁹

A histologic feature of the Weber-Christian type of panniculitis not previously emphasized is the tendency for the interlobular connective tissue septums to retain the same width throughout. Edema, necrosis and infiltration may be present, but extensive fibrosis extending from the point where the larger blood vessels lie is usually conspicuous by its absence. Thus it seems that the changes occur mainly as a result of appearance of lipophagic cells around the smaller blood vessels within the fat lobule. The foam cell resembles that of xanthoma and, without regard to controversy regarding its origin, it is of the phagocytic type and is variously called "histiocyte," "polyblast," "granuloma cell," and so on. These cells at times are clumped, with coalescence of their cytoplasm forming multinucleated giant cells. Similar pathologic pictures resulting from actual

trauma,²⁰ the injection of oily and other foreign substances, bacterial and nonbacterial,¹ and recently a group of various physiologic solutions, have been seen. In spite of the lack of knowledge regarding the etiology and exact nature of chronic relapsing febrile nodular nonsuppurative panniculitis, one may conclude that it may represent not a disease entity but simply a syndrome involving a particular reticulo-endothelial response.

SUMMARY

In reviewing the literature on relapsing febrile nodular nonsuppurative panniculitis and analyzing the cases reported which seem to demonstrate typical clinical and histologic features, the following characteristics stand out clearly. From a clinical standpoint these are (1) recurrent attacks of malaise and fever, of widely varying degree, accompanied by subcutaneous nodules, (2) predominant occurrence of the condition in adult women, (3) localization of the subcutaneous nodules on the trunk or extremities but mainly on the thigh, and (4) a tendency to subcutaneous atrophy with resultant depression at the site on involution. The histologic features are (1) edema and necrosis, primarily involving the subcutaneous fat, (2) diffuse appearance of cells phagocytic for fat, with a few multinucleated cells, (3) very limited fibroblastic stimulation, (4) notable absence of epithelioid nodules, (5) infrequent severe vascular changes, and (6) primary involvement of the entire fat lobule.

Although the etiology is unknown, the clinical pathologic features suggest that panniculitis is a syndrome rather than a disease entity. Examination of the patient and studies of blood cultures and of the nodules themselves give no information as to its origin. The clinical and pathologic features suggest that relapsing febrile nodular nonsuppurative panniculitis represents a special reticulo-endothelial response in which drugs, particularly iodine, may be a precipitating factor. The syndrome may result in death.

ABSTRACT OF DISCUSSION

DR. E. W. NETHERTON, Cleveland: Only a few reports of relapsing febrile and nodular nonsuppurative panniculitis have appeared in the American literature and most articles have been based on the observation of a single case. Dr. Bailey is to be congratulated on being able to report such a large number of cases presenting the characteristics of this syndrome. It is of more than passing interest that this disease may occasionally prove to be fatal. This is the first report of a fatality attributed to this disease. Dr. Bailey referred to a case which I presented before the Cleveland Dermatological Society in 1933. The patient did not have the febrile reactions which have been observed in other cases. However, the dimpling of the skin following the disappearance of the nodules, the relapsing of lesions that were limited to the subcutaneous fat, and other characteristics that have been mentioned by Dr. Bailey were present. The pathologic changes did not show the acute leukocytic type of reaction that was first described by Weber but simulated the chronic type reported by Christian and others. The etiology of this syndrome is unknown. Two points may be emphasized as having some bearing on the etiology: (1) the high incidence of obvious foci of infection and (2) the frequent history of the ingestion of bromides and iodides either prior to or during the active phase of the disease. The distribution and

location of the lesions and their character of relapsing suggests that the etiologic agent, whether chemical or of infectious nature, is blood borne and that the nodules are in reality metastatic lesions. In my case and in Dr Bailey's series, obvious foci of infection involved the teeth and tonsils and in case 1 of this series an otitis media developed during the course of the disease. Although a careful study failed to demonstrate an organism in the first case reported by Dr Bailey, the severity of the clinical manifestation, the type of febrile reaction and the fatal termination can best be explained in the presence of some type of systemic infection. There is a history of ingestion of bromides or iodides in all of Dr Bailey's cases. In the future the blood, urine and tissues should be examined for excessive amounts of iodine or bromine in cases with this type of panniculitis. Dr Bailey is correct in concluding that relapsing febrile nodular nonsuppurative panniculitis is a syndrome or a special reticulo endothelial response which may be precipitated by drugs, particularly iodine and bromine, and possibly by bacteria or their toxins that arise in foci of infection.

DR RICHARD J. BAILEY, Rochester, Minn. I appreciate Dr Netherton's discussion, particularly his emphasis on the possible etiologic role of infection. In respect to the changes described by Drs Weidman and Besancon in their discussion of erythema elevatum diutinum (*Arch. Dermat. & Syph.* 20:593 [Nov.] 1929), a careful histologic study of the sections from the cases reported did not show the particular vascular change which they described. Relapsing febrile nodular nonsuppurative panniculitis undoubtedly occurs much more frequently than a review of the reported thirteen cases would indicate. It is interesting that, in a general review of changes of the subcutaneous fat, both clinical and experimental, one finds that the reaction of this tissue is of three types: (1) a nonspecific response with fibrosis predominating; (2) a so called tubercloid response, with numerous epithelioid cells; and (3) a preponderantly phagocytic response. Weber-Christian disease apparently falls into the latter group.

THE GONORRHEA PROBLEM IN THE UNITED STATES

R. A. VONDERLEHR, M.D.

Assistant Surgeon General, United States Public Health Service
AND

LIDA J. USILTON, M.A.

Statistical, United States Public Health Service
WASHINGTON, D. C.

The physician or health officer interested in the gonorrhea problem finds an extremely high incidence of the disease and great economic loss and human suffering due to it. He is puzzled not only by the relatively inadequate methods available for prevention and treatment despite the fact that the etiologic agent is known but also by the difficulty in determining the period of communicability and by the need for a practical diagnostic procedure which may be applied easily and as a routine. Without a knowledge of these essentials he encounters almost insurmountable difficulties in controlling the infection. The vast extent of the problem should serve as a challenge both to health officers and to physicians to develop a more effective control program.

INCIDENCE

The seriousness of the problem is indicated by recently completed surveys of the United States Public Health Service in which attempts were made to determine the number of cases of gonorrhea required each year in the United States.¹ It is estimated from the

assembled data that there are annually 1,037,000 cases of acute gonorrhea. In addition, there are a similar number acquiring the infection who annually are forced to seek treatment although the infection has passed the acute stage.

As any experienced health officer would, in a campaign against an infectious disease, an attempt has been made to determine the extent of the dissemination of this infection through the population. Such facts have

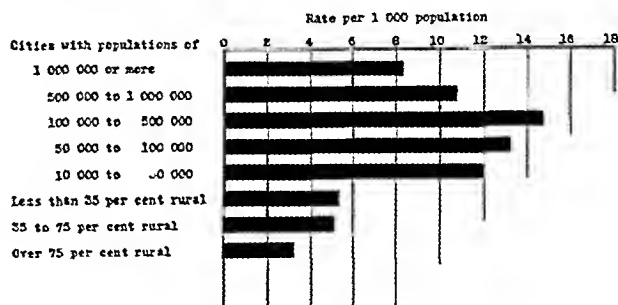

Chart 1—Annual incidence rates for acute gonorrhea per thousand of white population

been established as the relative frequency of the occurrence of gonorrhea in the two sexes and the two predominating races; its geographic distribution, the age of persons acquiring the infection and the proportion of cases under the care of private practitioners as contrasted with those in public clinics. These surveys have been based on studies of all legal sources of treatment for approximately 10 per cent of the population of the United States. The geographic distribution of cases is general (chart 1). In cities of a million or more population, the annual rate for white persons who sought medical care during the acute stage of the infection was 8.3 per thousand and among Negroes 9.7 per thousand, as contrasted with a lower rate among the white in rural areas of 4.5 per thousand. Conversely, among the Negroes in rural areas the rate was 11.4 per thousand. It is interesting that the higher annual rates exist in cities of from 50,000 to 500,000 population while the lower rates occur in the metropolitan and rural areas. The ratio of acute to chronic infections in these areas indicate that proportionately one-half more white males than females seek treatment during the acute stage of gonorrhea. This neglect is far greater among the Negro than among the white females. For every Negro who seeks treatment in the acute stage, another delays coming to treatment until the infection is chronic, whereas among the Negro males two come to treatment in the acute stage for each one in the chronic stage, as shown in the accompanying table.

The effect of this delay on the part of the female in seeking treatment, added to the greater difficulty encountered in treating gonorrhea in the female, is resulting in an increased prevalence rate for women with chronic gonorrhea under the care of both the public clinic and the private practitioner. This evidence confirms the common belief that the female is the most frequent carrier of the disease.

AGE INCIDENCE

In a few of the later surveys, data were assembled with regard to the age of the patient on acquiring the infection. Based on these data the mean age for the white males is 29 years, for the Negro males 24 years, and for the white females 24 years. The age of the greatest number of infections is several years earlier

¹ Read before the Section on Urology at the Eighty-Eighth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1935.

in each instance Sufficient data have not been accumulated to determine the mean age for the Negro female Nearly half of the cases of gonorrhea were acquired before the age of 25 The effect of gonorrhea on the fertility of potential parents makes this early age of acquiring the infection more tragic It is estimated that 26 per cent of the cases of gonorrhea occur

in females, and of these 86 per cent are in the reproductive period between the ages of 15 and 44 years inclusive, that is, approximately 230,000 of the potential mothers of the United States acquire gonorrhea annually Of the cases of gonorrhea, 74 per cent were in males and 97 per cent were in patients between the ages of 15 and 54 inclusive (chart 2) It is a well known fact that gonorrhea is one of the most frequent causes of sterility Its exact importance is unknown Norris² reports from the literature that from 30 to 50 per cent of the cases of sterility in women are due to gonorrhea and that 60 per cent of all gynecologic operations result from this disease Gonorrhea is also a frequent cause of one-child sterility Further evidence of the ravages of this infection is found in the extent to which the presence of gonococci in the genital tract of the pregnant woman endangers the health and life of both the mother and the offspring

Williams³ states that gonococci not infrequently invade the genital tract and cause inflammatory reactions which lead to abortion Kroug⁴ was one of the first to present bacteriologic proof that gonococci cause

puerperal infection He claimed that he had been able to cultivate the gonococcus in fifty out of 179 puerperal cases Williams³ found gonococci in approximately 9 per cent of his febrile patients when suitable culture mediums were used Taussig and Stone⁵ state that from one tenth to one sixth of all rises of temperature in the puerperium are the result of gonorrheal infection Norris² quotes various figures, believing the most conservative to be from 5 to 10 per cent in parturient women Gonorrheal puerperal infection though rarely fatal per se, is always serious

PREVALENCE AND TREND

Data on the prevalence of gonorrhea were secured on twice as large a population group as were data on incidence Legalized sources of treatment serving 2 per cent of the nation's population were included Based on these data there are 493,000 cases of gonorrhea constantly under medical care in the United States Resurveys were made in seventeen of the communities originally surveyed after a period of from three to six years in an effort to determine, if possible, the effectiveness of present day preventive and control methods The resurveys indicated in general a decrease in the prevalence rates for gonorrhea However these data may not necessarily be interpreted as representing an actual decline in the frequency of gonorrhea because simultaneous surveys made for syphilis indicated that the rate for syphilis in this period had increased 3 per cent Syphilis and gonorrhea are comparable because these two diseases are contracted in a similar manner and there is twice as high an incidence rate for gonorrhea as for syphilis Furthermore, it is a well known

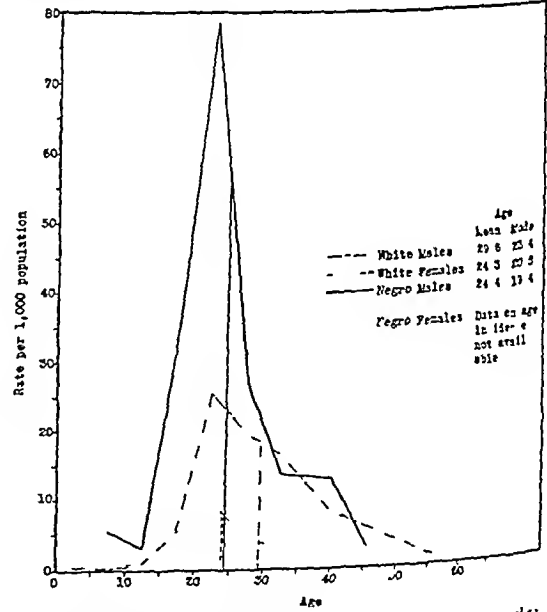

Chart 2.—Incidence rates per thousand of population for gonorrhea in Kansas, Nebraska and Richmond, Va.

fact that present day therapy is less effective in rendering the patient with gonorrhea noninfectious than the patient with syphilis

It is therefore believed that the apparent decline in the rate for gonorrhea is due to failure to provide treatment for the average patient rather than to the actual control of the infection This interpretation is based on the knowledge that throughout the resurvey period

5 Taussig and Stone quoted by Williams³

the curtailment of public health funds made it necessary for venereal disease clinics to limit the treatment of gonorrhea. In resurveyed communities in which facilities were more adequate the incidence rates for gonorrhea were proportionately higher, indicating that the number of infected persons under medical care is dependent on the availability of treatment facilities. Confirmation of this conclusion can be found in Nelson's report⁶ on the situation in Massachusetts, where efforts were made to maintain a venereal disease control program. He reports that over a ten year period, 1925-1934, a downward trend for syphilis was accompanied by an upward trend for gonorrhea in the rate of admissions both to public clinics and to private practitioners.

DECLINE IN GONORRHEA

That something can be done in the control of gonorrhea even with the methods at present available has been demonstrated by the medical corps of the armed forces of the United States. In the army, the annual admission rates for gonorrhea per thousand white enlisted men stationed in the United States has

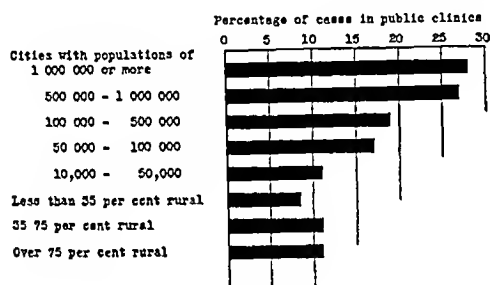

Chart 3—Percentage of cases of gonorrhea under treatment in public clinics

decreased 75 per cent from 91 per thousand in 1910 to 22 per thousand in 1934.⁷ There has been a steady downward trend throughout this period which the army authorities explain by the use of prophylaxis and compulsory physical examination. They anticipate further decrease with increased vigilance not only of medical but also of line officers. The navy likewise reports a reduction of 46 per cent in the admission rate for gonorrhea from 104 per thousand in 1910 to fifty-six in 1934. In the navy the ratio of gonorrhea to syphilis is decreasing. In 1910 it was 4.6 to 1 and in 1934 the ratio was 2.7 to 1.⁸

In a few of the European countries there is some evidence that there is a decline in the number of cases of gonorrhea, although in no instance is it as marked as the downward trend for syphilis. For example in Great Britain the number of cases admitted for the first time to any clinic for treatment for gonorrheal infections in 1928 was 30,425 males, which number decreased to 27,506 in 1935, a decrease of 9.6 per cent, which is fairly constant throughout the eight year interval.⁹ This downward trend and apparent control of gonorrhea in males are absent for females in Great Britain.

In Copenhagen there was a very definite decline in the number of cases of gonorrhea under treatment. Although the data are not presented separately for sex, the total number of cases of gonorrhea in 1919 dropped from 8,783 to 4,572 in 1933. This decline was not

apparent in other parts of Denmark. On the contrary, the number of cases was slightly higher in 1933 than in 1919.¹⁰

In Germany a decline of 34 per cent in cases of gonorrhea from 1927 to 1934 has been reported.¹¹ The number of cases reported dropped from 22,700 to 14,900.

PRIVATE PRACTICE AND PUBLIC CLINICS

The percentage of gonorrhea under treatment in public clinics decreases with the decrease in the density of population. In cities of 1,000,000 or over, 28 per cent of the patients go to public clinics, but this proportion decreases to 11 per cent in cities of from 10,000 to 50,000. The latter figure is approximately that of rural areas (chart 3).

GONORRHEA AND OTHER COMMUNICABLE DISEASES

A comparison of the number of cases of gonorrhea with that of the other common communicable diseases indicates the enormity of the problem. In contrast with 1,037,000 cases of gonorrhea annually, enough patients to populate a large state, there were in 1935 only one third as many cases of tuberculosis, one fourth as many of scarlet fever, one twenty-seventh as many of diphtheria, one fifty-eighth as many of typhoid and a hundredth as many of poliomyelitis. Gonorrhea may be said to be the great epidemic disease of the human race, and little has been done about it. Yet an epidemic of any of the ordinary communicable diseases arouses immediate concern and demands the immediate institution of intelligent control measures.

SUMMARY

1 Annually in the United States at least a million persons acquire gonorrhea.

2 The incidence of gonorrhea is highest in cities of from 50,000 to 500,000 population, and lowest in metropolitan and rural areas.

3 The mean age of acquiring the infection is 29 years for the white male, 24 years for the Negro male, and 24 years for the white female. The age of highest frequency of infection is several years younger in each instance.

4 A fourth of the cases of gonorrhea occur in females, 86 per cent in the reproductive period of life. Thus approximately 230,000 potential mothers in the United States acquire gonorrhea annually.

5 There are constantly under observation and treatment 493,000 persons with gonorrhea in the United States.

6 There is no substantial evidence that gonorrhea is on the decline in the United States. However, the medical corps of the armed forces of the United States has demonstrated that something can be done in the control of gonorrhea with the methods at present available.

7 A few European countries have reported a decline in the number of cases of gonorrhea, although in no instance is it as marked as the downward trend for syphilis.

8 The percentage of gonorrhea under treatment in public clinics decreases with the decrease in the density of population.

9 Gonorrhea is much more prevalent than any other serious communicable disease.

THE DIAGNOSIS OF GONOCOCCIC INFECTION IN THE MALE

AN EVALUATION OF LABORATORY METHODS

CHARLES M. CARPENTER, M.D.

ROCHESTER, N. Y.

The practice of modern medicine is becoming more and more dependent on laboratory aid for the diagnosis of infectious diseases. This is especially true in the diagnosis of gonococcal infection in the male, because genito-urinary symptoms similar to those caused by *Neisseria gonorrhoeae* may be caused occasionally by other bacteria. Not infrequently men become carriers of the gonococcus but show no symptoms of the disease. In this presentation the comparative diagnostic value of smears, cultures and complement fixation is considered.

THE SMEAR METHOD

Until recently the examination of smears for diplococci, tinctorially and morphologically typical of the gonococcus, constituted the chief laboratory method for diagnosing gonococcal infection. The inspection of smears properly stained by Gram's method has many merits. It is comparatively simple and inexpensive. Results of the examination are available within a few minutes after the specimen has been obtained. Smears on glass slides are easily transportable. Furthermore, the technic is a much less involved procedure than the cultural method and may be employed in the physician's office, provided the physician or a qualified technician is cognizant of the intricacies of staining by Gram's method. It is unnecessary to emphasize the unreliability of smears when stained with methylene blue. However, the examination of a smear stained with methylene blue, prepared from a typical case of acute gonococcal urethritis, usually presents such a characteristic picture that few errors arise.

The smear method is much less dependable in chronic cases, when the number of gonococci in the inflammatory exudate has decreased and secondary invading bacteria predominate. Some observers believe that the gonococcus becomes morphologically and tinctorially atypical and difficult to recognize in the latent stage of the disease.

THE CULTURAL METHOD

During the past three years the development of a dependable cultural method has demonstrated that the examination of smears properly stained by Gram's method fails to reveal many cases of gonococcal infection. Although many bacteriologists have successfully cultivated the gonococcus since its isolation in 1885 by Bumm,¹ a routine cultural method suitable for diagnosis was not available until McLeod and his associates² in 1934 introduced the use of chocolate agar and emphasized the value of reinforcing air with carbon dioxide for isolating the gonococcus. In addition, they described an oxydase test for identifying colonies of the gonococcus in mixed cultures. Later, Leahy and Carpenter³ modified McLeod's method and after employing it as a routine for three years, concluded

that it was the most reliable available procedure for diagnosing gonococcal infection. The technic is comparatively simple and may be used in any modern public health laboratory.

A diagnosis based on the isolation of the gonococcus makes possible its unmistakable identification and eliminates the defects inherent in the smear method. A report based on the recovery of the micro organism in culture is acceptable to the courts. Furthermore the use of a cultural method is necessary to evaluate accurately the results of any therapeutic procedure.

THE COMPLEMENT FIXATION TEST

The reliability of the complement fixation test is questioned by many serologists and the majority of urologists in America. Price⁴ of London as well as many other European serologists however, have much confidence in the test but the use of their methods in this country has given disappointing results. There are those who are pessimistic about the possibility of ever evolving a complement fixation test suitable for the routine diagnosis of gonococcal infection. It is evident that the various technics now employed in the United

Table showing Results from Eight Laboratories of Complement Fixation Tests for Gonococcal Infections on Four Patients

* History and symptoms of gonococcal infection (chronic anterior urethritis). Smears and cultures were positive when blood was taken.

† No symptoms but history of gonorrhea in September, October and November 1937. Smears and cultures were negative when blood was taken.

‡ No history or symptoms of gonococcal infection. Smears and cultures were negative when blood was taken.

States should be studied critically. The results from the use of our best procedures cannot, in many instances, be correlated with the patient's bacteriologic and clinical examinations. Several investigators⁵ have concurred in the opinion that the complement fixation test is especially useful in differentiating gonococcal arthritis from arthritis caused by other agents. It is undoubtedly more valuable in this type of infection than in the other forms of the disease. In a recent report Warren, Hinton and Bauer⁶ conclude that, "in cases in which the history is consistent with a diagnosis of gonorrheal arthritis, a positive test will be correct in 90 per cent of the cases." Furthermore, they state, "Of 239 cases representing other types of arthritis, 91.6 per cent gave consistently negative reactions."

A cooperative investigation by eight laboratories is now in progress to compare the results of complement fixation tests on the same specimens of blood from patients so isolated that reinfection cannot occur. The serologic observations will be correlated with the clinical

and bacteriologic observations, especially with the results of the culture method. This is the first attempt on a large scale to compare the technic in use in the United States. It is hoped that this study will aid in standardizing the test. Furthermore, research on improving the specificity and sensitivity of the test is in progress in several laboratories. It is evident that the renewed interest in this test will provide the information required to solve many of its present shortcomings.

The data in the accompanying table illustrate the present unreliability of the complement fixation test by showing the many discrepancies that occurred in tests made by several serologists on samples of blood from four adult male patients selected from a group of 300 patients. Fifty cc of blood was collected from each patient, after which a 5 cc specimen was forwarded to each laboratory for examination. Patient 85 had a chronic gonococcic urethritis of several months' duration. Smears and cultures were positive at the time the blood was tested. Patient 96 had a history of gonorrhea eighteen months prior to the examination of his blood. No symptoms were present and smears and cultures were negative when the blood was collected. Patients 215 and 216, because of mental and physical disabilities, could not have been exposed to a gonococcic infection except at the time of birth. Neither showed symptoms of the disease, and smears and cultures were negative when specimens of the blood were taken.

The following data will illustrate further the unreliability of the present serologic methods. The comparative results from the use of the complement fixation test and the smear and cultural methods on ninety-two patients with a history and symptoms suggestive of gonococcic infection are shown in the chart. The results from similar examinations on twenty-eight patients of the same character but with no history or symptoms of a genito-urinary infection, are likewise shown.

Complement fixation tests on eighty of the ninety-two infected patients gave reactions varying from a plus-minus to a four plus. In this group more positive diagnoses resulted from the serologic examination than from either the cultural or the smear method. Obviously, however, these results are questionable because twenty of the twenty-eight patients noninfected at the time of examination gave positive reactions. The history on some of the patients in the latter series may have been unreliable but it is unthinkable that 71 per cent were undependable and that no false positive reactions were obtained.

Cultures from either the urethral discharge or the prostatic exudate were positive in forty-six of the ninety-two cases while smears stained by Gram's method and examined by a bacteriologist with extensive experience were positive in only thirty-five cases. Twelve per cent more cases were diagnosed by cultures than by smears.

COMMENT

The data presented in this brief review show the comparative value of the complement fixation test, the cultural method and the smear method for the diagnosis of gonococcic infection in the male. The complement fixation test gave a positive reaction in 87 per cent of ninety-two cases presenting a history and symptoms of the disease. Its true value, however, becomes greatly diminished in the light of finding 71 per cent positive reactions in a group of twenty-eight patients with neither a history, symptoms nor bacteriologic evidence of the disease. The latter group, however, is small. In

a few instances false positive tests have occurred in patients with meningococcic infection. Likewise the use of gonococcus vaccines, or those incorporating other gram-negative cocci seriously interferes with the interpretation of a positive test. Further studies on gonococcus antigens are necessary to improve the specificity of the complement fixation test. The limitations of many of the present technics make its use questionable even when correlated with the clinical and bacteriologic changes.

The superiority of the culture method to the smear method, and especially to the complement fixation test is obvious from the data presented. The diagnosis of 12 per cent more positive cases by culture than by smears is significant. In females, however, approximately twice as many positive diagnoses are made by cultures as by smears. The cultural method gives no false positive diagnoses and, furthermore, is a reliable test for cure. It has not as yet become as useful an aid to the general practitioner as is the cultural method for the diagnosis of diphtheria. At the present time its availability is somewhat limited to hospitals and vene-

ON 92 PATIENTS WITH HISTORY AND SYMPTOMS OF GONOCOCCIC INFECTION

[REDACTED]	POSITIVE BY SMEARS—0

Results of complement fixation tests, cultures and smears on ninety-two patients with history and symptoms of gonococcic infection and on twenty-eight patients with no history or symptoms of gonococcic infection.

real disease clinics where well equipped laboratories are located so that specimens can be cultured within six or eight hours after collection. A few city health departments have introduced the cultural method and it will soon be possible to judge the value of this new diagnostic procedure under routine conditions.

It should be emphasized that neither the cultural method nor the smear method should be used alone, but as supplementary procedures. Although more positive diagnoses are obtained by the cultural method, smears occasionally reveal typical gonococci, which for unknown reasons fail to grow.

CONCLUSIONS

The cultural method is the most reliable procedure for the diagnosis of gonococcic infection, exceeding both the smear and complement fixation methods. The isolation of the gonococcus makes the diagnosis unquestionable and a report based on this finding constitutes irrefutable evidence in court. The smear method, however, has many advantages over the cultural method, because of such features as its simplicity, inexpensiveness and rapidity. It fails to reveal as many positive cases as the cultural method and in some instances, false positive results are reported, owing to

the inability of the examiner to differentiate the gonococcus from other bacteria. Furthermore, it is impossible to distinguish viable from nonviable gonococci.

The present methods for making complement fixation tests are unsatisfactory and frequently give false positive results.

ARTIFICIALLY INDUCED FEVER FOR THE TREATMENT OF GONOCOCCIC INFECTIONS IN THE MALE

STAFFORD L. WARREN, MD
WINFIELD W. SCOTT, MD
AND
CHARLES M. CARPENTER, MD
ROCHESTER, N. Y.

With the advance of chemotherapy, numerous drugs have been developed and used for the treatment of gonorrhea with the hope that a preparation might be found which was capable of quickly destroying the gonococcus without injuring the mucous membrane of the male urethra. The inadequacy of chemical treatment, in all probability, has been due to the anatomic structure of the male urethra and to the tendency of the gonococcus to become "fast" to germicides used locally. Search for a specific drug for intravenous use has likewise been disappointing. Comparatively recently, however, two related products, prontosil¹ and prontosil-in (sulfanilamide), have been heralded by a few investigators as specifics for meningococcal and gonococcal infections. While we have been using sulfanilamide in our clinic for some time, we feel that further studies must be made before its clinical value can be definitely determined. Antigonococcus serums, vaccines, filtrates, bacteriophages and the like have appeared to be useful for the treatment of certain cases of the disease but have not been successful as a routine procedure.² The local application of heat in the form either of hydrotherapy or of electrotherapy, while of great therapeutic value, cannot be relied on to produce an effective, consistent and rapid cure.

Cognizant of the disappointments that have so frequently befallen those who have enthusiastically advocated new methods for the cure of gonorrhea, we shall describe our experiences and present the results obtained during the last six years with the use of general fever for the treatment of acute and chronic gonococcal infection in the male. It is to be emphasized that the method described for inducing fever is not practicable for universal use but is strictly a hospital procedure requiring at least a seven day hospitalization for the ambulatory patient. It demands the services of full time day and night nurses specially trained to care for patients undergoing such treatment. Since the average length of fever treatments was 14.8 hours, as determined by the thermal death time, more time is demanded of the physician than is reserved each day for office practice. In addition

to requiring special nursing care, it is necessary that the patient be seen at frequent intervals by a physician, who must be available on short notice.

EXAMINATION OF PATIENT, PREPARATION FOR FEVER THERAPY, AND CARE DURING AND AFTER TREATMENT

A patient is never treated until after he has received a thorough physical examination and special preparation for fever therapy. First, a genito-urologic examination is made in order to determine the extent and degree of infection. Smears and cultures are made of the urethral exudate taken after the end of the penis has been washed with soap and water and a 1:4,000 solution of mercuric oxycyanide has been applied. The exudate for culture is collected on a sterile swab and suspended in 1 cc of Douglas broth. If, after the urethra is stripped, insufficient or no exudate is present, the first two or three drops of urine are voided into 1 cc of broth for culturing. In chronic cases in which an examination of the prostatic secretion is indicated, the patient is first instructed to distribute the contents of his bladder, as equally as possible, into three glasses. The glans penis is then thoroughly cleansed with green soap followed by the application of a 1:4,000 solution of mercuric oxycyanide, after which the prostate is massaged to obtain material for microscopic examination and culture. The secretion is permitted to flow into a test tube containing 1 cc of broth. A smear is also made from the prostatic exudate at the meatus. The urethra is never irrigated with an antiseptic solution before prostatic massage, because the presence of the chemical might inhibit growth of the gonococcus. The specimens are then submitted to the bacteriology laboratory for examination according to the technic described by Leahy and Carpenter.³ A specimen of blood is also obtained as a routine for complement fixation tests for syphilis and gonococcal infection.

When fever therapy is contemplated, the patient is admitted to the hospital. Further laboratory studies are made, including a complete blood count, a roentgenogram of the chest, an electrocardiogram and a chemical examination of the blood. A twenty-four hour specimen of urine is examined for specific gravity, volume and total sodium chloride. The details of the treatment are explained to the patient or to his guardian and a signed permit for such therapy is always obtained.

Special attention is given to the patient's intake of sodium chloride before he is subjected to the fever therapy. Marked losses of salt may occur during the treatment, and it is essential therefore that the tissues be well supplied before the fever is initiated in order to maintain a normal chloride and water balance. In certain instances it is deemed necessary to give the patient from 10 to 15 Gm of salt during a twelve or twenty-four hour period prior to the treatment. On the evening preceding the fever, the patient is given a cleansing enema. At 6 a. m. he receives the usual hospital breakfast and half an hour later a sedative which is usually from 8 to 15 cc of paraldehyde in grape juice. The patient is brought to the fever clinic at 7 o'clock where he is transferred to the radiant energy cabinet.

Restraints are set in place and the bulb of the rectal thermomometer is inserted into the rectum. Cultures and smears are again made from the urethral discharge when present, or from the first voided urine, a

check on the cultures made previously. A specimen of blood is collected and examined for nonprotein nitrogen, sugar, chloride content and icteric index. These observations constitute a basis for comparison after treatment. The rectal temperature is elevated to 41.5 C (106.7 F) and is maintained at this level for a period equal to the thermal death time of the strain of gonococcus isolated from the patient. To maintain a normal water balance, the patient is given from 200 to 350 cc of fluid each hour. If sweating is excessive, from 5 to 15 Gm of sodium chloride is given by mouth at intervals throughout the treatment. In the late fall and winter in this climate the use of supplementary chlorides is less necessary than in summer, even during a very long treatment. The pulse, respiration and temperature are observed and recorded every ten minutes. The blood pressure is taken at least once each hour and more frequently if deemed advisable. When paraldehyde narcosis is inadequate, it is supplemented with from 10 to 20 cc of whisky per hour.

The patient is under the constant supervision of a nurse specially trained for this type of therapy and is visited every hour by the physician. At the termination of the fever a specimen of blood is again taken for comparison with the results of the previous analysis. The cabinet is opened and the patient's temperature is allowed to fall. He is returned to his room after the temperature has receded to 38 C (100.4 F), if his general physical condition is satisfactory.

If the therapy is successful, all clinical symptoms disappear and cultures for the gonococcus are negative at the end of treatment. The urethral discharge usually subsides before the termination of the treatment. A small amount of whitish, mucoid urethral discharge may be observed within twenty-four hours, but no yellow pus is present. Cultures and smears are taken approximately twenty-four hours after treatment and again on the second and third days. A convalescent period of three days is usually sufficient, regardless of the length of the fever treatment. If the patient's clinical condition is satisfactory at this time, he is referred to his personal physician for follow up. Further urologic treatment is necessary in nearly all cases, except in early acute anterior urethritis in which no urethral injury, such as roughening or stricture formation, has occurred. The elimination of the gonococcus from the prostate and seminal vesicles by fever therapy is seldom followed by the complete disappearance of the secondary infection without the accepted routine treatment for such complications. Whenever possible, it is advisable that the patient have a rest period of about three weeks before an examination is made to discover the extent and character of any resulting sequelae.

DETERMINATION OF THE THERMAL DEATH TIME OF THE GONOCOCCUS

When a pure culture of the gonococcus has been isolated from the specimen submitted for bacteriologic examination, the thermal death time of the strain is determined.⁴ Observations have indicated that 41.5 C (106.7 F) is the highest temperature the body can safely tolerate for intervals of from eight to twenty-four hours. The duration of the period of fever is based on the thermal death time of the individual strain of the gonococcus at this temperature. The procedure employed is essentially the same as that previously

described.⁵ Sealed glass vials containing from 1.5 to 2 cc of a dextrose-ascitic fluid-blood broth culture of the gonococcus are immersed in a constant temperature water bath set at 41.5 C. A vial is removed at hourly intervals and its contents are cultured for viability. The hour after which no growth occurs is considered to be the thermal death time. Experience has shown that it is unnecessary to make routine hourly observations except from the eighth to the twenty-fourth hour after the immersion of the culture in the bath. Examinations made on 250 strains of gonococci have shown that the thermal death time at 41.5 C varies from six to thirty-four hours. The isolation of the gonococcus from the patient and the determination of its thermal death time require from seven to ten days. If contamination occurs during the examination the procedure must be repeated. As a rule ambulatory patients are not admitted to the hospital until after the test has been completed.

CONTRAINDICATIONS TO FEVER THERAPY

There are several contraindications to the use of fever for the treatment of gonococcal infections. Patients with electrocardiographic evidence of myocardial damage or heart block of any degree do not tolerate such therapy well. Mild valvular damage with full compensation, however, is not necessarily a contraindication in patients under 30 years of age. Patients more than 40 years of age should not be treated for fifteen hours or longer unless a careful study is made of the cardiovascular system and especially of the peripheral circulation. Patients with chronic alcoholism should not be treated by this method. Frequently patients are admitted to the hospital with an acute infection after an alcoholic debauch, mentally and physically prostrated. Nonalcoholic patients occasionally show signs of toxemia from a gonococcal infection such as pallor, restlessness, anorexia, insomnia, anemia, marked sinus arrhythmia and dyspnea on exertion. It is also important to exclude those rendered susceptible to heart prostration by a low salt intake during the summer months or by acute respiratory infections, and especially to exclude those with active pulmonary tuberculosis.

SEQUELAE OF THE TREATMENT

Of a total of 283 patients with gonococcal infections subjected to fever therapy, jaundice and severe nausea and vomiting have developed in fifteen. Four cases in which symptoms were present are reported in this paper. In two of them also hematuria was present, which disappeared within a week without further sequelae. These symptoms occurred only during the warm months of the year. The icteric index in some cases rose to as high as 18 by the third day (the normal value is from 4 to 8). There was a concurrent rise in the nonprotein nitrogen to double its normal value, but the latter subsided more rapidly than the icteric index. The blood sugar usually was unchanged. The serum chlorides either remained at a low normal or dropped below the normal content. They rapidly returned to normal, however, on the administration of sodium chloride subcutaneously, or by mouth if the patient did not vomit. The jaundice likewise responded favorably to the administration of from 15 to 20 Gm of sodium chloride within twenty-four hours. It subsided in from three to five days when the carbohydrate as well as the saline intake was increased. A discussion of these

details will be published in subsequent papers. Herpes labialis developed in approximately 60 per cent of the patients.

RESULTS OF FEVER THERAPY ON SIXTY-FOUR PATIENTS

We have included in this series only those cases in which positive clinical changes were confirmed by a positive smear and culture within the twenty-four hours before treatment was instituted. This made it necessary to exclude many cases in which such information was wanting as well as cases diagnosed by their clinical signs and symptoms only. Only those cases were considered cured in which the physical changes, the three glass test of the urine, and the smears and cultures from the urine, the urethra and the prostatic secretion were consistently negative for one month or longer after the fever therapy. The majority of the cases were observed for at least three months. Some have been under observation for a period of three years. In those cases in which treatment failed, symptoms accompanied by positive bacteriologic changes usually reappeared from one to three days later.

The practice of subjecting the patient to a fever equal in length to the thermal death time of the strain of gonococcus harbored by the patient quite naturally evolved from our failure to cure a large percentage of the gonococcal infections by a single fever of short duration. For the purpose of presentation, the cases have arbitrarily been divided into five groups.

GROUP 1—Three patients treated with one session of fever at 41.5 C for less than five hours

The thermal death time of the gonococcus from one patient was nineteen hours but that from the other two was not determined. The duration of fever was two, three and four and one half hours. The patient given four and one half hours was considered "cured" that is, smears and cultures were negative after treatment and remained so during the follow-up period. Treatment was not satisfactory in the other patients since positive smears and cultures were obtained from both. In the case of the two hour treatment the patient refused to cooperate and treatment was discontinued. Fever was terminated in the other patient after three hours because of marked cyanosis. The thermal death time of the gonococcus from the patient who was "cured" was not determined.

Obviously no conclusions can be drawn from such a small group. In a large series of patients a few would undoubtedly be cured by a fever of very short duration. This would be especially true of the acute case which had almost run its clinical course and in which recovery probably would have occurred without treatment. Every effort was made, however, to exclude such cases from this series.

GROUP 2—Seventeen patients treated with one five hour period of fever at 41.5 C

Only three of seventeen patients who received five hours of fever at 41.5 C at one sitting were cured. Two of the patients reported as cured harbored strains of the gonococcus with thermal death times of fifteen and twenty-two hours respectively, while in the third the thermal death time of the strain was undetermined. No explanation can be offered as to why cures were obtained in these three cases while failure resulted in the fourteen others unless it was because of a difference in the individual patient's resistance against the disease. This defense mechanism, however, cannot as yet be accurately measured. It is of interest to note the long

period of local treatment (from one to four months) required to cure those patients who failed to respond to one five hour session of fever at 41.5 C.

GROUP 3—Four patients treated with two sessions of fever at 41.5 C of duration shorter than the thermal death time

Since a single five hour session of fever failed to cure many patients the use of two or more short fever treatments of from five to ten hours' duration was tried. Favorable reports of employing a series of short periods of fever for the treatment of gonococcal infections have been made by Hensch, Slocumb and Popp,⁶ Bierman and Horowitz,⁷ and Simpson,⁸ as well as by several other investigators.

In three of the cases in which the first treatment failed subsequent fever therapy proved to be of no value. One patient suffering from urethritis and arthritis was cured of the urethritis after a five hour session of fever while the arthritis responded to a second treatment of six hours. There is a possibility, however, that in this instance the two treatments supplemented each other. Although cures may be effected by repeated sessions of fever of short duration our interests have been concerned chiefly with the use of a single session of fever equal in duration to the thermal death time of the strain of the gonococcus isolated from the patient. This principle in our opinion is the rational basis for treating infectious diseases with induced fever. This is especially true in gonococcal infections because of the thermolability of the gonococcus at fever temperatures.

GROUP 4—Nine patients treated with a session of fever at 41.5 C longer than five hours but shorter than the thermal death time

Only two of nine patients so treated were cured. One of them received a fourteen hour session of fever which was six hours less than the thermal death time. The other patient whose strain of gonococcus had a thermal death time of twenty-seven hours was cured by a fifteen hour session of fever. Three other patients who failed to respond to fever therapy recovered after four weeks of local chemical treatment. That they may have received some benefit from the fever is evidenced by the shorter period of time required to effect a cure by subsequent chemical treatment.

GROUP 5—Thirty-one patients treated with one session of fever at 41.5 C approximately equal to the thermal death time

Included in this group of thirty-one cases are five in which the duration of treatment was from one half to two hours shorter than the thermal death time. The method of determining the thermal death time of the gonococcus is not without error. A variation of from one to two hours has occurred in repeated tests on the same generation of some of the strains. Because of a slight variation in the thermal death time it was found advisable whenever conditions permitted to subject the patient to fever for one hour longer than the reported thermal death time.

The results obtained in this group of thirty-one patients were the most satisfactory. There were only two uncomplicated cases of acute anterior gonococcal urethritis. The remaining twenty-nine presented one or

6 Hensch, P. S., Slocumb, C. H., and Popp, W. C. Fever Therapy Results for Gonorrheal Arthritis, Chronic Infectious (Atrophic) Arthritis and Other Forms. *J. A. M. A.* 104: 1779 (May 18) 1935.

more complications that constituted difficult problems of treatment. Twenty-five, or 81 per cent, of the patients were cured. Failure occurred in six instances. Two of these patients responded to simple local treatment within two weeks after the fever and the third was cured in three weeks. In these three cases it was evident that the fever therapy either increased the resistance of the patient or decreased the virulence of the gonococcus, so that local treatment resulted in a rapid cure. One patient whose strain of gonococcus had a thermal death time of eleven hours, failed to respond to a five hour treatment but later was cured by fifteen hours of fever.

The failure to cure six, or 19 per cent, of the patients in this group was due possibly to the fact that each was infected with two or more strains of the gonococcus. Should this premise be true, the determination of the original thermal death time was evidently made on the least heat resistant strain. Thermal death time determinations on five of the six strains recovered from the patients after the session of fever indicated this.

One death occurred.

A boxer, aged 22, in good physical condition presented a simple anterior urethritis of three weeks duration. The strain of gonococcus isolated from the urethral discharge had a thermal death time of twenty-four hours. On physical examination the patient was normal except for the presence on the right temple of an unhealed wound produced by a blow received during a recent boxing match. The patient was given 8 cc of paraldehyde one-half hour before the fever treatment and whisky in amounts of 5 cc at approximately hourly intervals totaling 184 cc for the twenty-four hour period during which time he was subjected to a temperature of 41.5 C. It was noted that the ingestion of small amounts of whisky produced a state of complete narcosis almost immediately thereafter. He stubbornly refused to drink the usual allotment of water (from 200 to 300 cc an hour) during the last five hours of treatment. Very little sweating occurred during the last half of the treatment which in the light of our present knowledge is an indication for termination of the treatment or for an infusion. However 1500 cc of 0.85 per cent saline solution and 5 per cent dextrose was given by infusion at the end of the treatment. The blood serum chlorides were 542 mg per hundred cubic centimeters and the nonprotein nitrogen 63 mg at that time. The patient reeked of paraldehyde and whisky but could be aroused. Ten hours later another 1500 cc infusion was administered and he drank some water spontaneously but refused food. No urine was voided.

Twenty-two hours after the termination of the twenty-four hour fever treatment, the nurse observed a sudden change in the patient. The pulse was feeble and the skin dry. It was impossible to arouse the patient for thermal observation. He was given 1 cc of caffeine and 0.5 cc of epinephrine subcutaneously and intravenous injections of saline and dextrose solution were attempted but were unsuccessful even after direct exposure of the vein. The patient responded to the usual oxygen-carbon dioxide mixture at first but soon pulmonary edema developed and he died shortly thereafter (twenty-six hours after the end of the period of fever). There was a terminal rise of 2 degrees C (3.6 F) in the rectal temperature. Autopsy disclosed moderate dehydration of all body tissues. There was frothy material in the bronchi and trachea and a very mild cloudy swelling of the liver. No hemorrhages were observed in the adrenals or other tissues. Permission to examine the brain could not be obtained.

Several factors probably contributed to this death. 1. The patient a professional boxer, was "trained down fine," and was further dehydrated and depleted of chlorides by the fever. Therefore the fluids given during the treatment were inadequate. 2. The patient had a marked intolerance to whisky (as little as 5 cc was a toxic dose). This was later verified by the family, who stated that he could not tolerate more than one cocktail and "never drank." 3. It is our belief that caffeine and

epinephrine were distinctly contraindicated in this case. Undesirable reactions have occurred from their use in other cases with low blood pressure or collapse after fever therapy. 4. A possible cranial lesion, such as pachymeningitis, resulting from his occupation may have been present and contributed to his death, but this could not be proved.

This is the only fatality that has occurred in a group of 283 patients (male and female) treated for gonococcal infections. Nevertheless we are convinced from further study of the water and chloride balance that it is possible to administer these prolonged fevers safely. Evidently this fatality was due in part to our inability at the time to recognize the incipient symptoms of dehydration in time to prevent it.

Because a number of cases which had previously resisted chemical treatment responded favorably to it after ten or fifteen hours of fever therapy, it seems advisable to discontinue treatment at the end of fifteen hours regardless of the length of the thermal death time, when there is the slightest cause for apprehension for the safety of the patient.

COMMENT

In an attempt to evaluate correctly fever treatment of gonococcal infections in 105 male patients, rather exacting requirements were specified. In only sixty-four cases was clinical evidence of the disease substantiated by a positive smear or culture within twenty-four hours of treatment. Failure of such substantiation resulted in the elimination of forty-one cases from the series, although very satisfactory clinical results were obtained. Every case reported as cured was observed for many weeks, and in most instances several months after treatment. Many of the patients have resumed marital relations without evidence of recurrence or infection in the partner. The decision to base the duration of fever treatment, wherever possible, on the thermal death time of the individual's strain of gonococcus was made when a high percentage of failures occurred after either one or a series of short sessions of fever was administered. Furthermore repeated treatment of five hours' duration proved less economical in certain cases, and not infrequently the patients refused to continue the therapy after two or more failures.

Fever therapy is indicated in those cases in which other types of therapy have proved to be of no value. It may well be considered in cases that fail to respond to the usual general and local therapeutic measures. Fever has proved to be a valuable asset in the treatment of the various complications resulting from gonococcal infections. In this series several patients having acute posterior urethritis, prostatitis and unilateral epididymitis were cured and the possibility of bilateral epididymitis and sterility was thus prevented. Gonococcal arthritis is most effectively treated by fever. Likewise in gonococcal infections of the kidney, a relatively rare but frequently most difficult complication to treat locally, fever therapy should be of special value. Artificially induced fever should be considered in the treatment of patients who refuse to cooperate while under local therapy and thereby not only prolong their own infection but continue to spread the disease. In married people in whom the welfare of the home and the prevention of domestic complications are dependent on a rapid cure, fever is frequently indicated.

This type of fever therapy should not be entered into lightly by either the physician or the patient. The physician should be certain in each case that its use is warranted and that the patient is qualified physically for

the treatment. When the treatment is to be relatively long, and in most instances it is (the average thermal death time in this series was 14.8 hours at 41.5 C), the patient should be advised that it is not devoid of risk and may be exhausting and unpleasant. At the present time, at least in all cases in which the thermal death is more than fifteen hours, fever therapy should not be attempted until all other therapeutic measures have been tried and found to be unsatisfactory. This statement is prompted by the fact that one of our patients suffering from an acute anterior urethritis died after a twenty-four hour fever treatment.

CONCLUSIONS

1 The results obtained in sixty-four male patients treated by artificially induced fever for gonococcal urethritis and its complications indicate that it is a valuable therapeutic procedure.

2 Cures resulted in seven of the thirty-four cases of gonococcal infections in which either a single session of fever or repeated sessions at 41.5 C shorter than the thermal death time were given. They were usually of five hours' duration.

3 In thirty-one cases of gonococcal infection in which the patients received treatment equivalent to or greater than the thermal death twenty-five, or 81 per cent, were cured by a single session of fever at 41.5 C.

4 This type of fever therapy is a procedure requiring trained personnel and is suitable for use only in a hospital. It is not devoid of risk, as is indicated by the occurrence of one death in 283 cases of gonococcal infections treated during the past six years.

5 Fever therapy is indicated in persistent and complicated cases of gonococcal urethritis in which other types of treatment have failed.

277 Alexander Street

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. VONDERLEHR AND LIDA J. USILTON,
DR. CARPENTER, AND DRS. WARREN, SCOTT
AND CARPENTER

DR. WILLIAM BIERMAN, New York. That artificially induced fever is a valuable therapeutic procedure for the treatment of gonorrheal urethritis and its complications in male patients is undebatable. That the *in vitro* thermal death time of a particular strain of the gonococcus isolated from a given patient bears an exact parallelism with the thermolethal influence of a submission of the living human host to a fever of the same height and duration is debatable. 1 It has been the experience of Drs. Warren, Scott and Carpenter and of others that the gonococci have disappeared after an inadequate treatment, as judged by the thermal death time *in vitro*, or after the fever therapy when subjected to chemical applications. 2 When the gonococci survive an initial heating, they disappear following subsequent treatments of no greater duration and temperature. This common clinical experience is in sharp contrast to the statement that "a comparison of the thermal death time of strains of the gonococcus before and after inadequate fever therapy has shown that the strains recovered after exposure to such a fever may become more heat resistant." 3 The percentage of favorable results reported by those giving shorter fever treatments is about as good as that reported in this series. 4 The changes in the blood, such as the marked leukocytosis with a shift in the Schilling scale to the left, the increased phagocytic activity and the changes in the immunology may well be additional defense factors. 5 When the rectal temperature has reached a level of about 106 F the temperature of the pendulous urethra in the male may vary from 0.3 degree F higher to 2 degrees F lower than the rectal temperature as I have found by clinical thermometers inserted into the urethra to a distance of about 1 inch from the meatus. 6 The authors do report failures when the human host was subjected to a temperature sufficiently high and sufficiently long on the basis

of previous *in vitro* studies. That 19 per cent of such failures was "due possibly to the fact that each of these patients was infected with two or more strains of the gonococci" may be incorrect if the previously made assertion that "a comparison of the thermal death time of strains of the gonococcus before and after fever therapy has shown that the strains recovered after exposure to such a fever may become more heat resistant" is correct. 7 Resistance to heat may conceivably parallel resistance to the other factors exerting a lethal influence on the organism. A microorganism when in the spore state, for example, may resist a greater amount of heat as well as a stronger chemical agent.

DR. HENRY B. GWINN, Washington, D. C. The value of any therapeutic procedure is largely dependent on its practicability. There are few institutions in which it is possible to determine the thermal death time of the strain of gonococcus with which each individual patient is infected. Other groups have modified this technique. At the Mayo Clinic one treatment of ten hours of fever between 106.6 and 107 F is given as a routine and about 90 per cent of the cases are reported bacteriologically and clinically cured. Those not cured in one treatment are given additional treatments. Even this technique means that the patient spends about thirteen hours in the fever therapy department. This necessitates two shifts of personnel. My associates and I have adopted a method that has given satisfactory results, has insured as far as possible the safety of the patient, and also fits into the routine of the average hospital. We give a trial treatment of two hours of fever of 105 F, which conditions the patient's skin and cardiovascular system and also serves to allay any fear he may have. Then each patient, barring complications, is given six hour treatments of from 106.6 to 107 F at twenty-four hour intervals. Most of our patients are both clinically and bacteriologically free from gonococci at the conclusion of the first or second regular treatment. Those cases which are stubborn can often be speeded up by the instillation of 10 per cent solution of mild protein silver at the height of the treatment. This method of treatment not only utilizes the bactericidal action of the fever but also permits the natural immune bodies of the individual to assist in the procedure. We have had patients with chronic gonorrheal infection who for one reason or another discontinued treatment while still showing both clinical and bacteriologic signs of infection nevertheless completely clear up in a few days without additional treatment of any kind. This would seem to indicate that either natural immune bodies are mobilized by the fever or else the organisms, weakened by the fever, are an easier prey for antibodies. Dr. Antoine Schneider and I are at present studying the effect of hyperpyrexia on individuals who have been on a restricted protein diet. We believe that certain individuals who have been on this regimen may develop a peripheral neuritis resembling that of avitaminosis because their inadequate protein reserve has been drawn on by the increased metabolism caused by hyperpyrexia. It would seem advisable to increase the protein intake of such patients and also to supplement this with a preparation containing vitamin B₁.

DR. RALPH H. JENKINS, New Haven, Conn. Dr. Deming, Dr. van Wagenen and I have been working for the past four years on the effects of estrogen on the urogenital tract of a male monkey and on gonococcal urethritis in man. The injection of 9000 international units of theelin (the estrogenic hormone) into a male monkey, weighing 2,450 Gm., resulted in an epithelial hyperplasia and metaplasia in specific parts of the urogenital tract. The one or two cell deep cuboidal epithelium of the verumontanum and the epithelium of the branched and penile urethra became stratified in type and from fifteen to twenty-five cells in depth. Cornification of the superficial layers gave it the appearance of vaginal epithelium. We attempted to treat a series of cases of acute anterior gonococcal urethritis in man with this substance. We found the dose to be the large part of the problem. In a series of more than thirty cases of acute anterior gonococcal urethritis in man treated with theelin doses ranging from 2,000 to 200,000 international units gave no conclusive evidence of definite cure. Not one of these patients developed any evidence of posterior involvement during the course of treatment. Thus may be significant. No local irritation resulted from the administration

of the theelin, nor were there any unfavorable general symptoms noted. During the past year we treated two boys with this infection. The response was so encouraging that I shall report these cases. One boy, aged 5, received 2,000 international units of theelin intramuscularly every other day until 30,000 units had been administered. Symptoms progressively improved after two weeks. There was no evidence of the disease after seven weeks. Another boy, aged 6, received 10,000 international units of theelin intramuscularly daily until 90,000 units had been administered. Symptoms progressively improved after nine days. There was no evidence of the disease after three weeks.

DR EMILY DUNNING BARRINGER, New York. In the compilation of the nine laboratories that are making this comparative study of the complement fixation, Dr Archibald McNeil is not included, the man in America who has done more for the complement fixation than any other one man. The research group at the Kingston Avenue Hospital, which has been faithfully working on this problem for seventeen years, is not in that group either. I should like to ask Dr Carpenter what his proof of cure of the female cases he treats with fever therapy is. In my experience the finding of the gonococcus in women varies with the stage of the infection. In the acute and subacute stages it is found relatively easily by spread and culture. In the chronic stage, however, the finding of the gonococcus by these methods drops so that only from 10 to 15 per cent of cases can be so diagnosed. It is in this chronic stage of gonorrhea of the adult female that we are pressed hardest for diagnosis, and it is in this group that the complement fixation test is of the greatest value. I agree with Price of London that this test is essential as a test of cure. Price warns about a misinterpretation of a negative result in the male and urges that this always be checked by culture and spread. There are cases in the male, for instance, of infection of the seminal vesicles or prostate when by massage a closed infection has been changed into an open one. With this drainage established, the antibodies do not form. On the contrary, in women it is in this chronic stage with closed drainage or latent foci that cannot be reached as in the male, that a large number of positive reactions are obtained. The reliability of the complement fixation test is a moot point in America mainly because of its alleged false positives. There are a number of reasons for this. Some of them are as follows: 1. Confusion in the readings. Some workers rate their readings of the test higher than others, and their three plus or four plus may only rate a plus-minus reading with Price, McNeil, Thomson and Haniman. 2. Faulty antigen or faulty technic, as the reading of the test too quickly. 3. Insufficient appraisal of clinical symptoms. 4. The possible cross fixation with antibodies of other gram negative cocci, as *Micrococcus catarrhalis* or the meningococcus, *Micrococcus flavus* particularly type 2. The possibility of this occurrence is relatively rare. Price quotes that in a series of 7,000 cases there were only two possible cases in which *Micrococcus catarrhalis* could not be excluded. I should like to ask Dr Carpenter whether he knows of any other more reliable test to take its place and whether he thinks one has a right to consider a case of gonorrhea in a woman cured when the only laboratory tests used are those in which in advance one could expect to get positive results in only 10 to 15 per cent of cases.

DR WILLIAM P. HERBST, Washington, D. C. I know of two instances in which serious neurologic disturbances followed the hyperthermic treatment, one resulting in a condition which was diagnosed as a poliomyelitis. I have a suspicion that it was not poliomyelitis. The patient's lower extremities, the bowel and the rectum were paralyzed. In another case weakness occurred first in the lower extremities about three days after the completion of a series of five or six hyperthermic treatments. The treatments were given at Gallinger Municipal Hospital, where there is a Kettering cabinet under the direction of Dr Gwynn. The symptoms progressed steadily over a period of five days until the upper extremities were involved necessitating rather attentive nursing care. The patient has gradually improved, and the improvement, I think, was in part due to the administration of vitamin B₁ along with physical therapy. As laboratory procedures such as serum fixation tests are undependable in the majority of laboratories, it seems

to me that it will have to be thrown out of consideration as a diagnostic procedure in gonorrhea. That leaves the cultural method and the stain method. The cultural method also depends on the laboratory which is performing it, and I do not believe that the majority of laboratory culture reports can be relied on. The detail of the making of the culture is important. The penis in the male is not prepared in any way when the culture is made. The patient himself has to hold the glans to keep the prostatic secretion which is expressed and washes down through the urethra from coming out until the test tube containing the medium is put at the meatus and the material allowed to run down in the tube. The medium must be at body temperature. It is then put in the incubator and corked with a solid cork, not a cotton cork. That is another important detail brought out with the carbon dioxide method described by Dr Scott.

DR CHARLES M. CARPENTER, Rochester, N. Y. In response to Dr Barringer's questions, may I say that in our experience we have found the cultural method to be far superior to the complement fixation test for diagnosing gonococcal infection and for determining when the patient is cured, second, Dr Archibald McNeil was invited to join our cooperative study but found it impossible to carry on this work. In the third place, the serologist whom Dr Barringer has employed for carrying on her complement fixation studies is testing the blood samples submitted to seven other laboratories.

DR S. L. WARREN, Rochester, N. Y. Because one patient with a gonococcal infection may be cured by one hour of fever at a low level, whereas another patient may fail to be cured by twenty-seven hours of fever at 41.5 C, it is evident that these extreme variations make any analysis of the situation very difficult. For this reason we have tried to be conservative in our analysis of the data obtained from patients. There is no doubt that the variation in the patient's own resistance to the disease plays a considerable part in his recovery or failure to recover from the disease. The application of the thermal death time principle has suggested the proper biologic explanation of these variations in the amount of fever required to cure the patient. A fever with a duration of only 20 per cent of the thermal death time will often cure a patient who is in good physical condition, especially patients with acute infections. On the other hand, a fever as long as 80 per cent of the thermal death time has failed to cure some patients although the clinical symptoms have subsided to a great extent. There seems to be no correlation between the chronicity of the infection and the length of the thermal death time to justify the postulate that the organism which is most resistant to chemical agents would necessarily be resistant to fever. With regard to Dr Bierman's criticism, in our treatment the thermocouple measurements during fever (with the patient in the radiant energy cabinet and with loin cloths in place) show that the urethra is within 0.2 degree C of the rectal temperature. The use of the cultural method as improved by Dr Carpenter has now enabled us to fulfil criteria for cure in a far more accurate manner. On the other hand, as Dr Barringer points out these criteria may fail in the female when the tubal structures have been sealed off. In our experience, when there are no gonococci present in the cervix, urethra and vestibular and urethral glands after fever treatment we have been unable to find any clinical or laboratory data to suggest that the patient still harbors gonococci in the genital tract. The best test of cure is the biologic one of the reassumption of marital relations or the marriage of the patient with resultant childbearing without complications. That has happened in seven of our series of 100 cases, both male and female and in five of the males alone. I would like to emphasize Dr Scott's statement that fever therapy is essentially a complicated hospital procedure requiring trained personnel (both physicians and nurses). We believe that it should be carried out only in those cases which have failed to respond to other methods. In our hands the technical cost of the procedure as outlined is about \$40 per treatment. Although repeated short fever treatments are often successful, we feel that it is more economical and less strain on the patient to attempt to cure him by means of one treatment the length of which is determined by the test of the organism, i. e., the thermal death time.

POSTOPERATIVE CARE IN SURGERY OF THE BILE TRACT

R L PAYNE, MD

NORFOLK, VA

The conclusions reached in this paper are based on personal experience and a study of 750 consecutive operations on the bile tract. In the past twenty-five years there have been notable advances in the diagnostic approach to, and the technical handling of, operations on the bile tract. On the other hand, postoperative care has been most tardy in its development. In fact, methods of handling patients after operations on the gallbladder and common duct have shown practically no changes. Little progress has been made, and most of the methods used even at this time are highly empirical and differ according to each surgeon's experience.

When a gallbladder has been removed or the common duct opened the immediate consideration is the care of the patient during the first forty-eight hours. Sedation with opiates hypodermically or with chloral and bromides by rectum is necessary, but these methods of employing drugs must be left to the experience and the dictates of good judgment, which should always be governed by the requisites of the individual patient. Vomiting in this forty-eight hour period should be especially guarded against, lest retching displace an important ligature or the fixation and suturing around the drain.

I am quite certain that in many cases postoperative hemorrhage from the cystic artery and bile leakage from the cystic or common duct develop as a result of early postoperative vomiting, and it is my custom to employ continuous decompression of the stomach with a Jutte tube introduced through the nose when the first tendency to retching or vomiting occurs. While the hypodermic administration of opiates and the administration by rectum of chloral and bromides combined are very helpful in allaying gastric and duodenal reversion, yet continuous decompression of the stomach by the indwelling nasal tube, in my opinion, is more valuable than all other measures.

Of equal importance are the maintenance of fluid balance and the support of the glycogenic function of the liver with dextrose. It is my custom to administer 1,000 cc of 10 per cent dextrose intravenously immediately after every operation on the bile tract, and this procedure is usually repeated eight hours later on the first postoperative day, twice on the second postoperative day and once on the third and the fourth postoperative day. In addition, if the patient is toxic and dehydrated an additional 1,000 cc of saline solution is given, making a total of 3,000 cc of fluid given intravenously in twenty-four hours, until the patient is able to take fluids freely by mouth. If the intravenous route is impossible to utilize for various reasons a fluid balance is then supplied by subcutaneous administration, and dextrose is added in the strength of 2.5 per cent. If necessary to supply a sufficient fluid balance, it is my custom to employ the large bowel by giving 500 cc of warm tap water slowly every four to six hours until the colon becomes irritable and has a tendency to reject the water. Contrary to the custom of many surgeons, I allow my patients to have ice and water by mouth from the beginning of the postoperative convalescence, provided they show no tendency to vomit.

Immediately after operations on the bile tract, and for several days thereafter, the possibility of postoperative pulmonary collapse must be borne in mind and, when present, dealt with according to the recognized measures acceptable for this complication.

In the first two or three days after my operation on the bile tract, I have learned to recognize the possibility and danger of acute toxic liver incompetence which may result fatally. This condition is characterized by an unexplained, very high fever and a state of depression accompanied by respiratory and circulatory weakness and is often associated with marked mental apathy and even coma. If the common bile duct has not been drained, one must fall back on determinations of the xanthoprotein, indican and cholesterol esters in the blood. Becher¹ has clearly demonstrated that in severe liver damage and particularly in hepatic coma the xanthoprotein of the blood is high and the indican low. The chemistry of the blood differs in uremia in which the xanthoprotein is high and the indican high. The normal level of xanthoprotein in the blood is from 15 to 25 mg per hundred cubic centimeters by colorimeter measurement, and the normal level of indican varies from 0.04 to 0.32 mg. I have recently observed a case of acute yellow atrophy of the liver in which the xanthoprotein was 148 mg and the indican 0.064 mg. Epstein² has convincingly summarized and recorded his personal experience showing that in liver damage there is a marked lowering of the normal ratio between the cholesterol esters and the total cholesterol in the blood. In parenchymatous degeneration of the liver he has shown that the cholesterol esters are markedly lower and, further, that a progressive rise in the cholesterol esters is definitely significant of a favorable prognosis. Preferably, determinations of the xanthoprotein, indican and cholesterol esters in the blood should be done before operations are undertaken on the bile tract, and daily checks of these constituents should be carried out postoperatively. Without these determinations one unfortunately has nothing but the clinical symptoms to depend on for recognition of this toxic liver failure, and so far the only therapeutic remedy is dextrose and saline solution administered intravenously. If dextrose and saline solution are regularly administered in the beginning, as outlined, it is possible that the disaster of acute toxic liver failure will be prevented. According to Ravdin³ there is an excess of fat in the liver in parenchymatous disease. When there is an excess of fat in the liver it is a question whether dextrose is the remedy for liver failure associated with a low glycogen content and a high fat content of the liver. There must be some way first to learn that there is an excess of fat and second to mobilize it. This is not known at present. Protein is probably the remedy, but determinations of blood proteins should be done first by the method of Moore and Van Slyke. If the values are low transfusion and the administration of less dextrose have given favorable results in a few of my cases. If the common bile duct has been drained one is at once supplied with hepatic bile from which certain evidence may be obtained that in many instances will foretell impending liver incompetence and thereby one has a guide in treatment and prognosis. This phase of the problem will be dealt with later in this paper.

POSTOPERATIVE HEMORRHAGE

Bleeding from the cystic artery, from large radicles in the gallbladder fossa or from injury to the hepatic artery or vein can be dealt with only by the usual surgical principles. However, jaundiced patients and those with severe liver damage resulting from acute infection and toxemia often show a tendency to continuous and prolonged postoperative bleeding which frequently ends fatally. According to my experience any forecast concerning this serious complication cannot be based on a preoperative determination of the coagulation and bleeding time of the blood. One of the most suggestive guides that one may follow is a very slow sedimentation rate of the blood, as suggested by Naegeli.⁵ For proper clotting of blood it is essential for fibrinogen to be present in sufficient quantity to unite with thrombin. It is generally believed that in liver damage there is a decrease in the fibrinogen content of the blood and that consequently there is a marked slowing in the sedimentation rate unless acute infection is present. Proper consideration must be given the factor of anemia in determining the sedimentation rate.

It has been claimed repeatedly that an excess of bile salts in the blood prevents coagulation by interfering with the formation of fibrin through the combination of thrombin and fibrinogen. Von Falkenhausen and Sauer⁶ stated that coagulability of the blood is not influenced by the presence of bile or bile salts in the blood stream. They claimed that severe liver damage associated with jaundice results in slowing the coagulation from an increase in antithrombin. Blood transfusion is the only specific treatment that I know for postoperative hemorrhage associated with icterus and liver damage. If slowing of the coagulability of the blood in this type of hemorrhage is due to an increase in antithrombin or anticomplement, as stated by von Falkenhausen and Sauer, then one may logically conclude that thrombin is the essential agent supplied by transfusion. In addition to thrombin, however, fibrinogen is supplied by blood transfusion, and thus the remedy has a dual capacity of counteracting the increase in antithrombin and the decrease in fibrinogen which are believed to exist in the blood after severe liver damage associated with icterus. Suffice it to say that blood transfusion should be repeated daily or twice daily until a favorable response is established. Many surgeons believe in treating this condition by repeated small transfusions, and in some cases I have known as many as fourteen large transfusions to be given over a period of seven days with favorable results.

DRAINAGE

After cholecystostomy or cholecystectomy many surgeons, of whom I am one, still believe in putting some type of drain down to Morrison's pouch or into the foramen of Winslow. The question is commonly asked: When should this drain be removed? The majority of my surgeon acquaintances believe in leaving it until the seventh day, their argument being that a fistulous tract is not established in a shorter period. I usually remove the soft drain by the fourth day, and if there is a tendency to nausea and vomiting I often lift it about 1 inch (2.5 cm.) at the end of the first twenty-four hours. In my opinion the only danger that can arise from removing it on the fourth day depends on the common tendency of most surgeons to close the layers of the abdominal wall too tightly around it at

the time of operation. This drain merely provides a lead or outlet, and if the opening through the abdominal wall is not too snug, serum, blood or even bile will find its way to the surface without difficulty. Furthermore, a drain left in for a week or ten days often provides for a slowly healing fistulous tract, which does not occur if the drain is removed around the fourth day. When to remove a drain from the gallbladder must depend largely on the pathologic changes observed in the viscus at the time of operation, the condition of the patient and the judgment of the surgeon based on a rather large clinical experience. I regret to say that I cannot lay down any rule for removing a cholecystostomy drain, for I have not done a cholecystostomy during the past twenty years.

DRAINAGE OF THE COMMON DUCT

Drainage of the common duct is indicated for the following conditions: (1) inflammatory, infectious process of ducts, acute or chronic, (2) obstruction from stone or stricture, making necessary decompression of the liver, (3) conditions demanding physiologic rest to the ampulla and the sphincter of Oddi, (4) pancreatitis, (5) malignant obstruction. It is with these conditions that the question arises: When should the drainage tube be removed from the common duct?

TABLE 1—Criteria for Removing Common Duct Drain

- (a) Chemical study of bile
- (b) Microscopic study of bile
- (c) Patulence of sphincter of Oddi

TABLE 2—Diagnosis of Cholangitis

Hepatic bile	Bile salts level decreased
	Calcium level decreased
	Cholesterol level increased
	Chlorides level increased
Liver damage severe	Cholesterol esters decreased
	Xanthoprotein increased
	Indican decreased

It is in this problem particularly that so little intelligent progress has been made and it is surprising to note how dogmatism and empiricism prevail in the customs of so many surgeons of wide experience in surgery of the bile tract. For instance, one active surgeon in New York expressed the opinion that when the catgut suture which anchors the tube to the common duct is absorbed the tube is ready to be removed. Another New York surgeon expressed the opinion that when the bile has been macroscopically clear for from three to five days the tube should be removed. A very active western surgeon stated that he leaves the tube in one month if no infection is present and from two to six months if infection is present. An active Boston surgeon stated that he leaves the tube in twelve days in the absence of infection and thirty days in the presence of infection. Another Boston surgeon who has done a tremendous number of operations on the bile tract said that he takes the tube out of the common duct in nine days provided there is no infection and on the twenty-first day if infection is present. A most prominent and well known southern surgeon stated that he removes the tube in all his cases on the tenth day whether infection is or is not present. This surgeon believes that tubes in the common duct conduce to stricture.

I have never observed stricture of the common duct from this cause and have left tubes in the common duct from six to fifteen months. My experience leads

⁵ Naegeli, Otto. *Blutkrankheiten und Blutdiagnostik*. Berlin: Julius Springer, 1931.
⁶ Von Falkenhausen, M. and Sauer, W. *Ztschr. f. d. ges. exper. Med.* 5: 398 (Sept. 15) 1927.

me to believe that there are three points to consider in maintaining or terminating drainage of the common duct (1) the liver factor—function normal or depressed, (2) the duct factor—inflammatory cholangitis, (3) the sphincter factor—sphincter spastic, inflammatory or obstructed. When inflammation, stricture, stone or new growth produces obstruction of the ducts, the intraductal pressure usually rises, and when it exceeds the hepatic secretory pressure, liver dysfunction, incompetence and often degenerative changes result. It is therefore evident that a common duct drain must be utilized for the purpose of decompressing

the presence or absence of bile salts, the level of bile chlorides, the cholesterol level and the presence of pancreatic ferments. Under no circumstances should the tube draining the common duct be removed until the bile salts have returned and the bile chlorides and cholesterol have come down to normal levels.

It is a common experience in cases of prolonged obstruction of the common duct for the first ounce of bile to show a total absence of bile salts and for the bile chlorides to measure from 700 to 800 mg per hundred cubic centimeters, thus indicating severe liver incompetence. In some of these cases with severe liver damage there often follows a rise in the level of bile chlorides, which I have seen go as high as 1,800 mg per hundred cubic centimeters, indicating that there has been a too sudden decompression of the liver, with a further impairment of function comparable to that commonly observed with sudden decompression of the kidneys by drainage of the urinary bladder in cases of prostatic obstruction. This condition may be somewhat combated by Reid's⁹ method of hydrostatic control of the bile output through the T-tube, provided the sphincter of Oddi is open sufficiently to shunt a small quantity of the bile into the bowel, thus cautiously diminishing the free egress through the T-tube. In some cases in which high levels of bile chlorides and low levels or absence of bile salts were noted, there occurred with the return of liver function, a gradual lowering of the chlorides and a return of the bile salts. When the bile chlorides reach a normal level of 450 to 550 mg per hundred cubic centimeters and remain stationary, I think it is safe to remove the T-tube provided the microscopic evidence of cholangitis has cleared up and the sphincter is functioning normally. In many of my cases normal levels of bile chlorides and bile salts appeared within the first seven to ten days, whereas in a number high chloride levels were maintained for two and one-half or three months. In no instances do I remove a T-tube until normal levels have been reached.

the liver and draining the inflamed ducts until they return to normal. It should be further maintained until obstruction at the sphincter of Oddi is overcome in order that the hepatic bile may empty freely into the duodenum. The criteria for removing a common duct drain must depend largely on three features: (a) chemical study of bile, (b) microscopic study of bile, (c) patulence of the sphincter of Oddi.

Research by Ravdin, Riegel, Johnston and Morrison⁷ demonstrated certain facts relative to liver function that can be applied clinically as criteria for the time of removing the common duct drain. These conclusions are as follows: In severe toxic liver damage the bile salts are diminished or absent in hepatic bile obtained through the common duct drain, and the bile chlorides, the levels of which normally correspond with those of the blood plasma, are increased. In cholangitis the bile salt concentration of hepatic bile is decreased, the calcium level is decreased, the chloride level is increased and the cholesterol level is increased. In disease of the gallbladder and in obstruction of the common duct one finds early and marked changes in the hepatic bile. The most important change is reduction of the bile salts below normal or a total absence of bile salts. The next most important change is an increase in bile chlorides. A return to normal levels of bile salts and a decrease in bile chlorides to normal plasma levels indicate a return of normal hepatic activity. In obstruction due to infection (usually with stones), the return of bile salts and bile chlorides to normal levels occurs slowly and late. In malignant obstruction (unassociated with infection), the bile salts and bile chlorides return to normal levels in a reasonably early period, from seven to ten days. Graham⁸ has shown that dyes given to determine liver function are eliminated from the blood quickly in the presence of malignant conditions and are retained longer and slowly eliminated in cases of obstruction associated with infection.

(a) *Chemical Study of Bile*—The first ounce (30 cc) of bile collected after institution of a drain in the common duct should be chemically studied to determine

2/10/36	495	Positive
2/10/36 T tube removed		

The chemistry of bile with regard to the presence of pancreatic ferments (lipase and protease) is important, as pointed out by Carter.¹⁰ If these ferments are found in bile, they usually indicate both obstruction at the sphincter of Oddi and absence of an accessory pancreatic duct opening into the duodenum. As previously noted, the cholesterol of hepatic bile is increased particularly in cholangitis, and therefore, if one is draining the common duct for cholangitis, the normal cholesterol levels should be reached in the bile obtained through the tube before the tube is removed. Reiteration is again made concerning the importance of cholesterol esters of the blood as they relate to liver impairment.

(b) *Microscopic Study of Bile*—With regard to removal of the common duct tube, a microscopic study

9 Reid, M. R. *Ann. Surg.* 78: 620 (Nov.) 1923.
10 Carter, R. F. *Surg., Gynec. & Obst.* 63: 163 (Aug.) 1916.

of bile obtained through the tube relates principally to the problem of inflammation of the duct. Owing to desquamation of epithelium and other processes of degeneration, the level of cholesterol is increased in cholangitis. Microscopically, this is indicated by the presence of cholesterol crystals. Cholesterol crystals disappear, with exceptions, rapidly and in most cases are absent after seven days of drainage of the common duct. In the majority of cases one will note that cholesterol crystals disappear under favorable progress in from two to three days. There are, however, three elements of importance that must be considered micro-

scopically, as follows (1) crystals of calcium bilirubinate, (2) mucus, (3) pus.

Calcium bilirubinate varies in the drained bile, appearing off and on in varying amounts during the entire time the T-tube is in the common duct. Mucus in varying amounts is continuously present while the tube remains in situ. Pus is the most important microscopic observation, and until all evidence of clumped pus cells disappears it is wise to continue drainage with the T-tube. When the calcium bilirubinate, mucus and pus are excessive, it is often extremely beneficial to irrigate gently through the T-tube each day with physiologic solution of sodium chloride. I have had no experience with Pribram's method of irrigating the common duct with ether, but in cases in which cholesterol crystals are excessive this measure might be worthy of consideration. Too little attention has been paid to the microscopic study of the bile in relation to a return to normal of the ducts, and with other factors favorable I do not think a T-tube should be removed from the common duct until removal is microscopically justified. The macroscopic appearance of drainage from the common duct is notoriously unreliable from both a microscopic and a chemical standpoint.

(c) *Patulence of the Sphincter of Oddi*.—There are seven guides from which one may draw conclusions relative to the passage of bile through the sphincter of Oddi into the duodenum: (1) injection of saline solution through the tube, (2) clamping of the tube, (3) test for bile in the stools, (4) food test, (5) Reid's hydrostatic method, (6) estimations of the serum bilirubin after the tube has been clamped for twenty-four hours, (7) x-ray visualization. If the sphincter is open and functioning normally, the administration of food will act reflexly on the sphincter permitting a flow of bile into the bowel. This is indicated by a diminished amount of bile outflow through the drainage tube.

With an unobstructed sphincter the gentle introduction by syringe of saline solution through the tube in quantities of 20 cc or more will cause no pain or discomfort, and, likewise, clamping of the tube in the absence of obstruction will shunt the bile into the bowel without pain or distress. If clamping of the tube can be maintained for twenty-four hours without distress, there is still a possibility that the normal egress of bile

into the duodenum is lacking. This can be definitely determined by estimation of the serum bilirubin before and after the tube has been clamped for twenty-four hours. An elevation of the serum bilirubin indicates the existence of some obstruction of the outflow of bile and is a delicate criterion which may be considered reliable as an indication of partial obstruction. Under no circumstances should injection of saline solution or clamping of the drainage tube be carried to the point where it produces pain or distress. Discomfort and an elevation of the serum bilirubin are the most important guides to indicate that these procedures must be stopped, and Reid's method of hydrostatic pressure and dilatation of the sphincter should be substituted.

X-ray visualization¹¹ is the most valuable method for determining the patulence of the sphincter of Oddi. The method consists of the placing of an x-ray plate under the patient and the introduction of hippuran through the T-tube. If there is obstruction, from 8 to 10 cc of hippuran will cause discomfort. An x-ray picture made at this time will show a block at the sphincter, and if there is a stone causing the obstruction it is readily outlined. If there is no obstruction, 20 or even 25 cc of hippuran may be slowly injected without discomfort, and the x-ray picture will show this emptying freely into the duodenum. This is a simple and harmless procedure and according to my experience very exact in its disclosures. The method is so satisfactory that it invites regular employment to the exclusion of other procedures if there is any question about the patulence of the sphincter.

It is important to remember that an open sphincter does not mean that a T-tube can be withdrawn. One must always remember that the chemical composition of the bile as it relates to the liver function, the microscopic appearance as it relates to the ducts, and the patulence of the sphincter of Oddi must all three appear to be normal before the tube is removed. One exception to this rule will be seen in cases of prolonged and well established cholangitis. In this condition chronic bilirubinemia is observed, and prolonged drainage of

bile by a tube in the common duct beyond a reasonable period does not conduce to cure. If all these factors are satisfactory, healing of the sinus after removal of the drain from the common duct is very rapid and, one might say, almost immediate. With the factors of liver, duct and sphincter normal, there is rarely more than just a spot of bile leakage after the removal of the tube, and in the majority of cases the external fistula appears to have closed within the first twenty-four hours.

If the fistula continues to drain bile or the patient has attacks of colic following the attempt of the fistula to close spontaneously, one may be certain that obstruction is present and should then resort without further delay to x-ray visualization of the common duct by the introduction of hippuran through the fistula or through

a small catheter introduced as deeply as possible into the fistula. This will give definite information concerning obstruction either by stricture or by stone. If one is unable to demonstrate a stone associated with external biliary fistula by x-ray visualization, one then hopes that the obstruction may be temporary and always awaits an indefinite period for the fistula to close. If the fistula does not close, x-ray visualization should be repeated and further operative measures considered according to the circumstances. If further operative measures must be undertaken for a persisting fistula I myself favor the Dobrotworsky¹² procedure in preference to the poor results obtained by attempting to anastomose the fistula into the bowel tract.

Sometimes the failure of an external biliary fistula to close is due to a spasm of the sphincter of Oddi and this is frequently characterized by repeated attacks of colic. This type of colic frequently occurs after cholecystectomy and after any type of operation on the bile tract. It is sometimes termed 'convalescent colic' and may be due to exaggerated tone, to hypertrophy and, at times to residual infection in the sphincter and the ampulla. Ivy called the condition hyperkinetic sphincter. Iwanago¹³ on the other hand, showed rather convincingly that after cholecystectomy there is incontinence of the sphincter of Oddi for from two to seven weeks, after which tone returns and dilatation of the common duct follows.

Furthermore, Puestow¹⁴ has shown that there is no bile secretion in a normal fasting animal with a normal gallbladder but that with the giving of food there is a free flow of bile. He showed further that after cholecystectomy in animals there is a free flow of bile in both the fasting and nonfasting states. Clinically, however, after removal of the gallbladder or removal of the tube from the common duct, there occur in some patients repeated attacks of colic which are probably not due to stone. For these attacks amyl nitrite by inhalation and glyceryl trinitrate in one-hundredth grain (0.00065 Gm.) doses under the tongue are the best therapeutic measures. McGowan, Butsch and Walters¹⁵ have demonstrated conclusively that morphine increases the intraductal pressure and does not give the relief afforded by the nitrites. Even in the presence of intermittent colic produced by stone, with block at the ampulla, I have seen glyceryl trinitrate give so much relief to one patient at the time of the colic that he was able to defer operative removal of the stone for eight months. I have repeatedly employed nitrites for the temporary relief of biliary colic since Dr. Walters first called my attention to this remedy about eighteen months ago.

MALIGNANT OBSTRUCTION

In cases of malignant obstruction associated with jaundice, due to new growth in or around the ampulla, it is frequently deemed expedient by the surgeon to do nothing more than institute drainage of the common duct with a tube. As previously stated, the danger of liver failure is less in cases of malignant obstruction than in cases in which obstruction is associated with infection.

However, in cases of malignant obstruction too sudden decompression of the liver is possible in the first few days after drainage of the common duct is

instituted and can be determined by rising chlorides levels and decreasing bile salts in the hepatic bile. The only suggested treatment, if the chlorides should rise to a rather high level, is to attempt an increase of intraductal pressure by the hydrostatic method of Reid¹⁶ or by the partial occlusion of the drainage tube. If the latter course is followed, there will always be danger of bile leakage around the tube. When a tube is placed in the common duct for the relief of malignant obstruction, it is advisable to instil frequently a little warm saline solution in the tube in order that the lumen may be kept open, because drainage by tube for this condition must be maintained indefinitely unless surgical restitution of the bile flow into the intestinal tract can be accomplished. In one of my cases of inoperable carcinoma of the ampulla, I left a tube in the common duct for fifteen months. When disintegration of the tube seemed imminent, I removed it and performed a choledochoduodenostomy after division of the common duct transversely above the obstruction.

ASTHENIA

When drainage of the common duct is accomplished by a considerable amount of diversion of bile there usually develops a type of asthenia which is due to functional disturbance of the patient's digestion and absorption. This condition is characterized by loss of appetite, weakness and general loss of well being, such as one would expect from a disturbance of intestinal digestion.

With the diversion of bile there is a loss of the electrolytic bases, consisting of calcium, sodium and chlorides, and, most important of all, a loss of bile salts which are so important from the functional standpoint of activating the lipases and the emulsification of the fats. Many years ago the surgeon learned to overcome this difficulty, and invariably met with a favorable response on the part of the patient, by returning to the intestinal canal the important agents in the bile so necessary in carrying out the extrahepatic function of the bile. Experience has taught that at least 4 ounces (120 cc.) of the patient's bile must be returned to the intestinal canal each twenty-four hours. The usual custom is to collect the diverted bile, chill it in the ice box and have the patient take two ounces (60 cc.) at a time by mouth after mixing it with a little grape-juice. The patient is told that it is a specially prepared milk which is given for the purpose of restoring his loss through the drainage tube. Occasionally a patient rejects this method of administering the bile and if this occurs a Jutte tube is utilized, and by this method larger quantities of the bile can be returned to the intestinal canal. This procedure of restoring the extrahepatic function of the bile should be resorted to in every case of drainage of the common duct as long as there is diversion of bile. I have met with no success by administering the various proprietary preparations of bile salts. When the sphincter of Oddi is patulous and the microscopic and the chemical studies of the hepatic bile do not necessitate free and prolonged drainage through the common duct tube, it is good practice to shunt the bile into the intestine by Reid's method of hydrostatic control, thus eliminating the necessity of returning the bile to the patient by the oral route.

Finally, I should like to emphasize the fact that proper preoperative study and preparation will often forestall postoperative complications.

ABSTRACT OF DISCUSSION

DR EDWIN P. LEHMAN, University, Va. I agree with most of what Dr Payne has said. I use duodenal suction even more freely than he advocates, often beginning it immediately after operation, and I have been impressed with the smooth postoperative course that usually follows. I also drain the gallbladder bed in the uncomplicated case following cholecystectomy, but I remove the drain at forty-eight hours, believing it of value only as a protection against immediate postoperative slipping of ligatures. I cannot too earnestly support the value of bile feeding for patients suffering from total loss of bile. Among the newer conceptions, the relationship of the nitrites and of morphine to common duct physiology is of outstanding importance. Dr Payne has in some instances presented biochemical observations rather more definitely than they warrant. Without belittling the fundamental importance of the work of Ravdin, the necessity to delay removal of the common duct tube until the bile approaches a normal chemical constitution is not clear. Is there any evidence that given a normally functioning sphincter of Oddi with free discharge of microscopically normal or nearly normal bile into the duodenum, the liver recovers its function any less rapidly than if the bile is escaping through the long limb of the T tube? Demonstration of a functioning sphincter is by far the most important criterion for the removal of the tube. C. S. Stone, working in the laboratories of the University of Virginia on liver glycogen and its relationship to diet in partially hepatectomized rats, observed that in animals fed on a high carbohydrate diet the liver glycogen was high, provided the animals were killed when the stomach was filled. If they were starved before being killed, however, the liver glycogen values were lower than any other observed in the entire study. Stone interpreted this phenomenon as an expression of increased insulin secretion stimulated by the days or weeks of high carbohydrate intake. When food is abruptly stopped, the excess of available insulin results in the rapid elimination of the liver glycogen. The phenomenon is presumably of the same nature as that which results in the so called paradoxical hypoglycemic reaction following sugar tolerance tests in the patient with low carbohydrate storage. Study of the liver glycogen in gallbladder patients under spinal anesthesia resulted in analogous observations. In a few instances the liver glycogen in patients, all on a high carbohydrate intake before operation, varied directly with the giving or withholding of a dextrose infusion on the morning of operation. The concentration of liver glycogen was as much as ten times greater when an immediately preoperative dextrose infusion was given than when it was withheld. These observations have a certain practical application.

DR HAROLD L. FOSS, Danville, Pa. The general principles in postoperative care, as laid down by Dr Payne are fundamental. There is not perfect unanimity regarding acute toxic liver incompetence. Not all authorities are agreed as to the entity of "liver death." Several significant contributions suggest that many patients who, prior to death, present symptoms of this rather indefinite syndrome are found at autopsy to possess fatal lesions quite unrelated to the liver. Until our knowledge of hepatic function becomes more definite, can we be sure of our ground regarding postoperative liver insufficiency? Becher, Hermann, Epstein and, especially in our country, Graham and Ravdin have made invaluable contributions in furthering our knowledge of these subjects. While the practicability of the biochemical studies referred to by Dr Payne and carried out postoperatively as a specific index of the patient's progress may possibly be questioned from them, no doubt, tests of great value will be produced. By the same token one might question the clinical value of chemical and microscopic examination of the bile as an indication of the appropriate time for the removal of the drains following choledochostomy. I should like to offer the thought that drainage, not only in cholecystectomy but also following choledochostomy, may in many instances be dispensed with. In feeling my way in my own operating room over a period of twenty years I have gradually reduced the number of cases in which drainage is established following cholecystectomy. With further perfection of technique and the acquirement of greater skill and experience, I find that with meticulous care in the control of

hemorrhage in the ligation of the cystic duct and in the closure of the liver notch, drainage becomes less necessary. If there is but slight cholangitis and the obstruction has been removed, I am convinced that following the removal of common duct stones, operators can greatly increase the number in which, after removal of stones from the common duct, the latter may be closed by means of fine silk without drainage and much to the patient's advantage. The T tube is a foreign body which the biliary passage strives strenuously to extrude, and although it has been left in for years as is often the case in plastic operations on the common duct, I am led to believe that common duct drainage occasionally does more harm than good. During the past year, less than one third of my patients had drainage following cholecystectomy and choledochostomy, and there has been a decided improvement in the progress these patients have made.

DR FRANK K. BOLAND, Atlanta, Ga. Some authorities declare that abdominal distention is due to air swallowing and not to fermentation. It is difficult to believe that fermentation is not an important factor in the causation of the abdominal distention as the condition frequently follows the taking of certain drinks the first few days after operation. Two drinks to which I have special reference are orange juice and grape juice. Grape juice causes gas pains but especially produces nausea. The nauseating qualities of grape juice in postlaparotomy patients are so constant that long ago I absolutely forbade its use. Orange juice is a pleasant beverage with rich vitamin content. The administration of orange juice, however, to a patient within the first few days following an operation on the biliary tract invariably causes gaseous distention. I am absolutely opposed to the use of this fruit juice at this time. I allow patients to have cold water and crushed ice within the first twenty-four hours of laparotomy, even though they vomit it. If the vomiting becomes severe and prolonged, all fluids by mouth are stopped and saline solution and dextrose are given by parenteral methods. The administration of fluid by retention enema, not proctoclysis, is a convenient, inexpensive method and in some way enables patients to void, obviating largely postoperative catheterization. The Levine tube is invaluable. The next fluid after water which can be safely given is ginger ale and perhaps tea or clear broth. Emile Holman, in a recent issue of *Surgery* calls attention to the value of frequently changing the patient's position in bed as a means of getting rid of gas. Long ago I learned that it was unwise to give the average patient an enema too early after operation. Intestinal tone is apt to be so much lessened that the bowel is unable to expel the enema with the result that distention and pain may be increased instead of decreased. Now I use a colon tube frequently for several days before ordering any enemas. Gas and fluids are usually withdrawn in this manner, and much relief is afforded. An enema need not be given for three or four days or even a week. Passage of gas may be facilitated by the administration of solution of posterior pituitary, pitressin or prostigmin.

DR WILLARD BARTLETT JR, St. Louis. It has been a great pleasure to hear this thoughtful presentation of Dr Payne's methods which he is using in an effort to substitute objective evidence for a mere routine in the postoperative care of patients with biliary tract disease. May I call attention to a method which I have been using since approximately 1930 in order to obtain further knowledge about such patients and accomplishing a certain amount of therapy in one small group of patients with biliary tract disease. This is the performance of a cystoscopy of the gallbladder through a biliary fistula maintained by a Pezzar catheter on those patients in whom cholecystostomy has been performed, either as the only contemplated operation on the biliary tract or as the first stage of a two stage attack on the extrahepatic duct systems. The cystoscopy of the gallbladder through the fistula should not be done under six weeks in order that the fistula may have become amply solid from the formation of the scar tissue. One is astonished to find how frequently many stones can be removed six weeks after operation when it is thought at the time of operation that the gallbladder has been completely emptied of stones. It is a most useful procedure. I reserve it for this particular group of patients and can recommend it heartily.

DR PETER B. SALITCH, New Orleans I was glad to hear Dr Payne say that there was very little to be done about the disturbance of the liver function postoperatively. One must always be careful in doing a cholecystectomy not to insult the liver, and as careful as one may be, one may have either a known or a reflex disturbance of the liver at the time of operation. In all my postoperative gallbladder cases I use epinephrine. I use between 5 and 10 minims (0.3-0.6 cc). If I have a bad case, I use 10 minims every three hours, or one of lesser gravity, from 5 to 6 minims. I cannot think of anything prettier than to watch the effect of the epinephrine. If one has a bad liver in a case of gallbladder operation, one will find as long as the liver is not functioning properly that there will be no reaction from epinephrine. How do I know when the liver is beginning to function? As long as the liver is not functioning, as I said, there will be no reaction. But as soon as the liver function is returning, the patient will have a decided reaction. Then I know that the liver function is returning to normal. If I have a bad case, I will not cut the epinephrine out altogether but will cut down the dose to, say, 5 minims (0.3 cc) every four hours, or 6 minims every eight hours. And the next day, if even 5 minims causes this reaction, I cut out the epinephrine altogether.

DR ROBERT LEE PAYNE, Norfolk, Va. Lest the chemical studies that I have shown seem complicated, I tried to cut down the slides to show that the principal things to study are bile salts and bile chlorides, and that is very simple. The Whitehorn test, the same test used for the determination of chlorides in blood plasma, and Pettenkofer's test for bile salts are all that is necessary at the present time. I am thankful to all who spoke in the general discussion, and particularly to Drs Foss and Lehman for questioning the value of these chemical studies. I do not know yet, in my limited experience, how valuable they are. They merely represent a stepping stone up from the empirical methods I have been following for years, and I have simply given what I have gotten out of them.

SEROLOGIC ANTIBODIES AGAINST HORMONES

JULIUS BAUER, MD

Professor of Clinical Medicine University of Vienna
VIENNA

One of the most interesting and striking discoveries in the field of endocrinology in the last few years has been the fact that extended treatment with certain hormone preparations is followed by a resistance of the treated organism to these substances. This phenomenon was first described for thyroxine by Abelin¹ in 1928 and has since been confirmed for a number of different principles, such as parathyroid extract, adrenal cortex extract and particularly the thyrotropic and gonadotropic principles of the anterior lobe of the pituitary. Collip² explained the phenomenon of hormone resistance by his theory of antihormones.

The antihormone theory as originally proposed was as follows. For each hormone there may be an opposite or antagonistic principle. This antagonist is present in the normal subject but may not be detected until it exceeds in amount the hormone substances with which it is balanced. The analogy was drawn between the hormone-antihormone complex and a chemical "buffer" system, and in this way the antihormone theory was related to the principle of inverse response. The postulated dual hormone control of peripheral structures is analogous to the proved dual nerve control (sympathetic and parasympathetic). The so-called antihormone was considered as a true hormone in every way and not as the result of an antigen-antibody response.

At the end of his article Collip restricted his theory as follows:

In view of the fact that a somewhat extensive search for evidence of the existence of antihormones to estrin to parathyroid hormone and to insulin has failed as yet to demonstrate such, it is possible that the antihormone theory should be applied only to trophic principles.

Several investigators have succeeded in obtaining positive serologic reactions (complement fixation, precipitins) against the gonadotropic pituitary hormone with the serum of prepared animals (Ehrlich,³ Bachman,⁴ Eichbaum and Kindermann,⁵ Brandt and Goldhammer⁶ and Twombly⁷). But, except for the first author, it has been admitted by all that the serologic antibody reaction was not specific against the hormone itself but against some traces of ill defined impurities of the hormone preparations used. They emphasized in accordance with Collip's opinion that the serologic antibodies had nothing to do with the antihormones that protect the animal against a special hormone and can be transmitted with the serum of resistant animals to untreated and nonresistant ones.

The problem entered into a new phase when my collaborators Schaechter and Kunewaelder and I⁸ succeeded in producing serologic antibodies against a well defined and pure chemical substance, thyroxine.

Our experiments have been carried out on rabbits. In these animals injections of thyroxine bring about a loss in body weight and a diminution of the serum lipase which is so constant that it can be used as a test for the effect of thyroxine. If rabbits are injected for a period of several weeks intermittently with small doses of thyroxine, they no longer react in this typical way, neither the body weight nor the serum lipase is diminished, they have become resistant to thyroxine. In this stage a positive complement fixation reaction with the serum of the rabbits can be obtained if thyroxine is used as antigen. In unprepared rabbits this reaction has always been negative, serologic antibodies have been produced by the prolonged treatment with thyroxine. Although the appearance of these serologic antibodies coincides with the biologic resistance of the animal against thyroxine, it seems that this resistance is not produced by the antibodies. The thyroxine resistance cannot be transmitted with the serum of resistant animals to untreated ones.

Based on these experimental facts we carried out complement fixation tests with thyroxine as antigen in a greater number of cases of hyperthyroidism and found this reaction to be positive in a high percentage whereas other cases not showing any signs of hyperthyroidism gave this reaction only occasionally. Among 103 cases giving a positive complement fixation reaction with thyroxine as antigen, forty-six were cases of a severe or moderate hyperthyroidism. Seventeen cases presented higher degrees of essential arterial hypertension, which so frequently is associated with symptoms pointing toward a hyperactivity of the thyroid. Permanent tachycardia, an elevated basal metabolic rate, vasomotor irritability, and an increased number of reticulocytes are signs to be encountered also in cases of essential hypertension presenting a positive

serologic thyroxine reaction In three cases presenting a positive reaction, thyroid preparations had been taken for a long time, because of obesity or some slight symptoms of thyroid insufficiency The other thirty-seven cases presenting a positive reaction included premortal conditions, febrile diseases and some conditions giving an extremely intensive complement fixation reaction with a syphilis or gonococcus antigen The great majority of patients who gave a positive reaction for syphilis or gonorrhea failed, however, to give a positive complement fixation reaction with thyroxine

The thyroxine reaction was negative in 330 cases, including twenty-four cases of slight or moderate hyperthyroidism Cured cases of hyperthyroidism gave negative reaction with thyroxine, in five of which the serum reaction had been positive before the operation, becoming negative after successful surgical treatment It was particularly striking that in one case as early as sixteen days, in a second ten days and in a third even eight days after the operation the serum reaction had become negative, whereas four days after the operation the reaction was still positive There was no difference whether the hyperthyroidism represented the typical syndrome of an exophthalmic goiter or whether it was a toxic goiter (toxic adenoma) Patients with myxedema always gave a negative reaction, pregnant women also gave a negative reaction From all these observations in animal experiments and human pathologic studies one can conclude that a positive complement fixation reaction with thyroxine is as a rule an indication of an abnormally high supply of the organism with thyroxine

The positive complement fixation reaction with thyroxine as antigen has been found not to be specific as far as the antigen is concerned Without exception diiodotyrosine as antigen gave the same result as thyroxine Also epinephrine and, in the majority of cases, also insulin can be used as antigens instead of thyroxine with the same results

In rare cases a positive reaction with insulin was obtained, whereas the reaction with thyroxine and the other antigens just enumerated was negative One of these cases presented a severe spontaneous hypoglycemia due to an insuloma of the pancreas proved later by operation This case has been reported by my collaborators Schur and Taubenhaus⁹ Two other cases of spontaneous hypoglycemia, free of any signs of hyperthyroidism, gave a positive reaction with insulin and also with diiodotyrosine It seems probable that in these cases the hyperinsulinism had provoked a production of serologic antibodies which in two of them were not limited to insulin in a specific manner but were extended to some related antigens Among quite a number of patients with diabetes treated with insulin only one gave a positive reaction to insulin and diiodotyrosine Signs of hyperthyroidism in this case were not present We had the opportunity of examining also the serum of five patients with schizophrenia who had been treated in the psychiatric clinic of Professor Poetzel with insulin shocks None of these serums gave a positive reaction

In a group of cases the complement fixation reaction was also tried with the synthetic substance sympatol which differs in its chemical formula from epinephrine only in the lack of one hydroxyl group in the cyclic ring This reaction paralleled without excep-

tion the reaction obtained with epinephrine and the other enumerated antigens Since it was evident that the serologic reaction with the different antigens thyroxine, diiodotyrosine, epinephrine, sympatol and insulin must be due to a chemical substance common to all, we tried to find this common constituent This constituent could not be any other substance than a para-oxyphe-nol ring or phenol itself Therefore we tried to find whether the reaction in the thyroxine positive cases could be obtained also with the constituents of diiodotyrosine The results were definite If the reaction with thyroxine and diiodotyrosine respectively was positive, it was positive too with tyrosine but negative with alanine And in these cases not only tyrosine but also phenol gave a positive reaction It was thus proved that the complement fixation reaction with these hormone preparations, which can be produced experimentally by the treatment of rabbits with thyroxine and which is to be obtained in the majority of cases of hyperthyroidism, was nonspecific and directed against the phenol group It was present in thyroxine as well as in the other hormone preparations and substances used in our experiments

In a series of experiments carried out on rabbits we found that a positive complement fixation reaction against the enumerated antigens could be artificially produced not only by prolonged treatment with thyroxine but also by such treatment with diiodotyrosine, epinephrine and inconstantly with insulin The appearance of serologic antibodies against insulin in these animals was not associated with a higher resistance of the animals against insulin, tested by their hypoglycemic reaction to an insulin injection Quite recently Taubenhaus succeeded in producing a positive complement fixation reaction with phenol as antigen in rabbits that had been injected for a longer period with small doses of phenol In some of these rabbits the complement fixation reaction with the syphilis antigen had become positive at the same time It is known that such a reaction is not infrequently observed also in untreated animals The aim of further investigations will be the elucidation of the nature of the serologic antibodies with which we are dealing

SUMMARY

1 A prolonged treatment of rabbits with injections of thyroxine leads to a resistance of these animals against thyroxine and to the appearance of serologic antibodies detectable by the complement fixation reaction

2 A prolonged treatment of rabbits with diiodotyrosine, epinephrine and frequently also insulin and phenol is followed by the appearance of serologic antibodies detectable by the complement fixation reaction

3 Most patients with hyperthyroidism give the same positive serum reaction, whereas in other individuals this reaction is negative as a rule

4 The complement fixation reaction is to be obtained in almost the same way with different antigens thyroxine, diiodotyrosine, epinephrine, sympatol, insulin, tyrosine and phenol Alanine has been found to give a negative reaction if used as antigen

5 Three patients with spontaneous hypoglycemia gave a positive reaction, one of them with only insulin as antigen

CONCLUSION

1 The extensive nonspecific complement fixation reaction involves different hormones and other substances containing a phenol group

⁹ Schur M and Taubenhaus M Ztschr f klin Med 128 292 1935

2 It is apparent that different degrees of endocrine hyperactivities such as hyperthyroidism and hyperinsulinism as well as experimentally produced states of hyperhormonization in animals may give rise to the appearance of nonspecific serologic antibodies

Mariannengasse 10

CRITICAL EVALUATION OF VACCINE THERAPY IN RHEUMATISM

EDWIN P. JORDAN, M.D.

CHICAGO

The criteria for the use of vaccines in the treatment of rheumatism are not yet clearly defined. It is hence necessary to examine the theoretical considerations supporting the use of vaccines. Their use demands the assumption that rheumatism—at least those types treated by vaccination—is due primarily to bacterial infection. Of necessity, therefore, an etiology or virus of non-infectious nature cannot now be considered in relation to vaccines. Adherents of such etiologic theories must thus be opposed to vaccine therapy as a rational procedure.

There are several possible modes of action of the bacterial proteins which presumably are the primary and active constituents of all vaccines. The first is by stimulation of immune body formation. If the immunization intended by the administration of vaccines is specific in nature, it can be effective only if the bacteria which are already present in the body and are causing the disease are not in themselves sufficiently antigenic to produce clinical immunization by the development of antibodies. The affirmation of this argument deserves careful thought and is at first glance not convincing. There seem to be no other diseases in which, during the actively infectious stage, vaccines can be given with definitely good therapeutic effects. Furthermore, up to the present, when preparing vaccines for use in rheumatism one is dealing with organisms that are not universally recognized as playing a causative role.

It is possible that immunization might result in a nonspecific manner. Thus, if immunity could be produced by a group of protein antigens it might not be necessary to use the specific organism causing that particular infection. Specificity seems of probable importance, however, when viewed in the light of longer experience with the immunologic specificity of such etiologic agents as the typhoid-paratyphoid group of bacteria. Specificity seems at the very least to be a desirable element in the further examination of the rationale of therapy.

The second possible therapeutic action of vaccines in rheumatism is by desensitization. If desensitization is a logical procedure in the treatment of rheumatism, it is necessary first to establish the fact of true protein sensitization. At present the conception of true hypersensitiveness rests largely on arguments by analogy. The work of Klinge, Swift and others indicates, it is claimed, a parallelism between rheumatic fever, or other manifestations of rheumatism, and true protein allergy. Klinge, for example, has produced histologic changes in experimental animals similar to those observed in rheumatism in man, by means of sensitization to horse serum. This factual observation, however, does not

mean that rheumatic fever in man is produced by horse serum, and caution must be exercised in implying that specificity is absent. Arguments for protein sensitization have also been based on observations of skin reactivity, while this line of investigation may be promising, the facts as yet remain difficult to interpret. Much work, therefore, remains to be accomplished before it can be said with any sense of certainty that the clinical manifestations of human rheumatism are truly due to protein sensitization. Furthermore, even if and when this proof is forthcoming, it will be necessary to determine what particular protein or group of proteins shall be used in the desensitization of human individuals. This will involve particularly the choice of bacterial strain or strains, the method of preparation, the mode of administration and the preferred dosages. Claims are even now made for autogenous bacteria, for the use of filtrates, for intravenous administration and for other variations in technique. Arguments can be advanced for or against these factors, but positive and final choice of methods cannot be made now. Investigations must be controlled carefully by thorough knowledge of the pathology, immunology and natural history of the disease.

In view of the fact that true rheumatism in human beings has not been satisfactorily reproduced in experimental animals, present investigations must be based on clinical observations. In many instances clinical observations are untrustworthy, but careful attention to control indicates that reliable conclusions are not wholly impossible. The thorough knowledge of the clinical course—both when patients are untreated and when they are treated by other means—and of laboratory tests, and a thorough understanding of the pathology may add considerably to the evaluation of therapeutic procedures.

Pending further evidence supporting the use of vaccines, it is well to examine the present status of their use in practice. Judging from the clinical type and known pathology, there are certain groups of rheumatism that would seem more likely than others to respond to treatment by vaccines.

RHEUMATIC FEVER

The clinical course of typical rheumatic fever is one which is usually somewhat self limited with regard to the recognizable active phase and in general does not last long enough for the close analysis of the results of treatment with vaccines. It seems difficult at present to judge fairly the effectiveness of vaccine treatment in a disease such as rheumatic fever, which may last actively perhaps only a few weeks. There are, however, types of rheumatism which in many respects resemble rheumatic fever but lack its dramatic quality of onset and acute febrile course and which last for months or even years. Some observers call this clinical syndrome rheumatic infection and ally it closely with the classic rheumatic fever. In some patients of the latter group, the course is so chronic that long continued therapy may be evaluated more satisfactorily. Personal observation leads me to believe that one characteristic of some patients in this group is an abnormally slow sedimentation rate of the blood. Similar rates are commonly noted in hay fever and other allergic diseases. This contrasts markedly with the rate usually observed in acute rheumatic fever. There is thus some support both from the clinical history and from a laboratory test that some members of this group are truly hypersensitive. Many of these individuals will show a married

exacerbation of symptoms following any sore throat or apparently minor infection. This change in symptoms is similar to that occurring in allergic individuals following increase in their exposure to the proteins to which they are sensitive. It is this group therefore, which seems to me to offer the most likely one for practical desensitization with vaccines. It is possible that the proper specific protein can be determined by means of cutaneous tests with organisms or their products and that definite clinical improvement may follow successful desensitization.

RHEUMATOID ARTHRITIS

The type of rheumatism most commonly treated with vaccines is rheumatoid arthritis. Much has been said and written about clinical improvement resulting from vaccine therapy in this disease complex. It is possible that some modification of the natural history of the disease does occur, but review of the literature indicates in many instances a lack of control over the necessarily prolonged period which places doubt on the value of the clinical conclusions. Thus it is generally recognized that rheumatoid arthritis goes through a natural history which is reflected by considerable variation in the subjective sensations of the patient. No definite periodicity has been observed. Nevertheless patients treated for periods of months or years will, in the vast majority of instances, develop periods of remission which often appear to foreshadow permanent improvement. This frequently occurs no matter what the treatment. Furthermore, satisfactory control of vaccine therapy from the standpoint of laboratory tests and pathologic modification, to my knowledge, has not yet been reported. The burden of proof, therefore, as to the efficacy of vaccine treatment in this type of rheumatism depends definitely on those who employ it as an established therapeutic procedure.

OSTEO-ARTHRITIS

There seems to be little scientific support for the use of vaccines in the treatment of pure osteo-arthritis when such exists. The infectious element, if any, appears to be negligible. Unless vaccines used in this disorder act in some nonspecific manner to stimulate the circulation and perhaps thus improve the subjective sensations, there seems little scientific basis for their continued use.

SPECIFIC ARTHRITIDES

In the specific joint diseases due to the pneumococcus, the gonococcus or other known organisms, long continued vaccine therapy either for immunization or for desensitization has not been generally employed. Other methods of therapy in general have given more satisfactory results.

CONCLUSION

The further evaluation of vaccine therapy in rheumatism depends largely on clinical proof, based on the choice of which patients may be most likely to respond to treatment, on the preferred method or methods of administration and on valid criteria for controlling the results. Until these points are carefully considered, the use of vaccines in rheumatism broadly considered, rests on pure empiricism. It is justifiable to employ them in selected cases under close observation with the object of obtaining more precise information. Their routine use, however, with any implication of certain cure cannot be too strongly deprecated.

CORRELATION OF THE POSITIVE REACTION TO TUBERCULIN AND THE SHAPE OF THE CHEST

S. A. WEISMAN, M.D.

MINNEAPOLIS

In a study previously made on the shape of the normal and of the tuberculous chest, it was found that the average normal chest was flat and wide and that the average tuberculous chest was deep and narrow.¹ It was also shown that the deep chest was an underdeveloped, primitive type of chest, resembling an infant's chest in shape. Later studies on the shape of the chest and on environment² showed that children from the poorer socio-economic environments had on the average a deeper chest, weighed less and were shorter than the children from the higher socio-economic levels.³ An investigation recently made on the incidence of tuberculosis in the various school districts in Minneapolis³ revealed that there is a very high incidence of tuberculosis among the children from the slums, where the deep chest prevails. Ten times as many cases of tuberculosis were reported from a school district which is perhaps the poorest in the city as were reported from the best school district.

Thoracic index and age of positive and negative reactors

Since the tuberculous chest is deep and narrow and since there is such a high incidence of tuberculosis among the children from the poorer districts, where the deep chest predominates, one should perhaps expect to find a higher incidence of the early manifestations of a tuberculous infection in apparently normal deep-chested children than in children with wide, flat chests. It is the purpose of this report to present such a study.

During the spring of 1936 the parochial school children of the city of Minneapolis were given the Mantoux cutaneous test by Drs. J. A. Meyers and N. M. Levine and members of the Minneapolis health department. I measured the chest diameters of 2,723 of these children and determined their thoracic indexes. (The thoracic index is the ratio of the depth of the chest to the width at the nipple line.)

Some time later Dr. Harrington of the Minneapolis health department sent me a list of the children that

gave a positive tuberculin reaction. The thoracic indexes of the positive and negative reactors were then compared. It is evident from a study of the accompanying graph and tables 1 and 2 that the children who reacted positively to the Mantoux cutaneous test had on the average a definitely deeper type of chest or a higher thoracic index than the children who did not show a reaction. After the ratio between the means of the positive and the negative reactors was determined, the mean ratio was calculated for statistical differences. The mean ratio was over 3 in each group, a fact of definite significance.

A positive reaction to tuberculin does not necessarily mean existing active tuberculosis. It does mean, however, that tubercle bacilli have gained entrance into the body, that there has been or is now an active form of tuberculous infection in the body.

Harrington, Meyers and Levine,⁴ in their recent report on "Significance of the Tuberculin Test," stated

The tuberculin test is extremely valuable in determining who in a family or in a community has foci of tubercle bacilli in the body. A positive reaction is diagnostic of the first infection type (primary complex) somewhere in the body. This type rarely causes significant illness but is always the forerunner of reinfection, destructive forms of disease, both acute and chronic, when this type develops. The tuberculin test, therefore, serves as a screen to select those who have been infected through direct or indirect exposure and who should be carefully examined and kept under close observation thereafter for the development of clinical disease.

There were 1,324 girls and 1,399 boys. The percentage of positive reactors was practically the same in each group of children, girls 11.95 per cent and boys 11.94 per cent (table 3). However, when the positive reactors were compared according to age, it was noted that the percentage increased (table 4). At the ages

of 7 and 8 the proportion of positive reactors was lower for the boys than for the girls. At the age of 9 there was almost twice the percentage of positive reactors among the boys as compared to the girls. At the ages of 10 and 11 there was a higher percentage of positive reactors among the boys but the difference was not so

TABLE 3—Incidence of Positive Reactions to the Tuberculin Test

15				15	5	33.33

marked as at the age of 9. At the ages of 12 and 13 the girls had a definite increase in percentage of positive reactors, whereas the boys tended to show a slight decrease.

COMMENT

This study, which shows that there is a definite correlation between the deep chest and the positive reaction to tuberculin adds one more link to the chain of evidence supporting the contention that the deep chest is more or less associated with tuberculosis. It also helps to explain why there is such a high incidence of tuberculosis among the poor in the slum districts. The children in the slums are physically underdeveloped. They are not only shorter and lighter but they have on the average a deep, primitive, infantile type of chest, one that has not gone through the normal process of development. Even the new-born and infants are shorter and lighter and have a deeper chest than the average infant from a better environment.

It may be well to reiterate here a statement made in a previous report. In many large cities the government is wiping out the slum districts and replacing them with modern, well built and well ventilated homes. This is a constructive, far-reaching piece of work and will do much to reduce the incidence of tuberculosis. In the future one will probably find a better developed child in these districts, not only a child who is taller and heavier than the average child in the present slum but one with a flatter type of chest, and in all probability there will be a marked decrease in the incidence of tuberculosis. Members of the medical profession can advance our aim of eliminating tuberculosis by acquainting the public with the part slums play in the fostering of this disease.

CONCLUSION

It appears that there is a positive correlation between a positive reaction to the Mantoux test and a deep chest in children.

ABSTRACT OF DISCUSSION

DR HARRY BAKWIN, New York The idea that tuberculosis has a constitutional as well as an environmental basis is not new but quantitative demonstration of this relationship is recent and today we have heard one of the only two contributions that I know of in this field, the other was made at Johns Hopkins University by Love, who studied the height and weight of army officers in whom tuberculosis developed. He went back to their old measurements and found that men who were tall and thin tended to develop tuberculosis more often than other groups. It is easy to understand why tuberculous persons should be thinner than other persons but it is a little difficult to understand why tall men should tend to develop tuberculous disease unless the strain of rapid growth which tall people are subjected to during puberty is sufficient to bring out the tuberculous process. I wondered whether Dr Weisman had studied any dimensions other than those of the chest. Is this change in the children infected with tuberculosis limited to the shape of the chest or is this part of a general alteration in body growth? Is it possible that the change in the shape of the chest is due to economic differences between tuberculous and nontuberculous children? I know Dr Weisman took all these children from a parochial school nevertheless I wonder whether it is possible that this was simply a poorer group of children who happened to be infected with tuberculosis or was the difference primarily tuberculous and not simply a social difference?

DR HAVEN EMERSON New York I should like to ask Dr Weisman whether he has any evidence of the relative incidence of tuberculosis in the populations from which these two respective groups of school children were brought. It is well to compare the physical types of children in a less favored group with those of a more favored group but still the cause of tuberculosis is the tubercle bacillus and not the shape of the body, and until the probable frequency of cases and deaths and infection in these different community groups is known, I should say the conclusion he presents remains unproved. There is a further control which Dr Weisman might be asked to present at some future session. There must be children of the well-to-do who also have these underdeveloped or persistently puerile type of chests, and one would like to know whether under the favorable, nontuberculous environment of the well-to-do such children have a higher incidence of tuberculosis than the children with the normal or more adult type of chest as they grow older. One remains uncertain, from an epidemiologic point of view, as to the significance of Dr Weisman's observations until evidence is given of the age-specific prevalence rates of tuberculosis in the communities from which these two sets of children were drawn.

DR L. M. ROHR Brooklyn I should like to ask whether racial groups similar to Dr Emerson's were considered in this study. If so, has Dr Weisman anything to say about the racial groups in it and the measurements of these children?

DR S. A. WEISMAN Minneapolis I could give only a summary of this paper. Time would not permit me to cover in detail all the work which has been done. However I wish to make one point clear. The person having a deep chest will not necessarily contract tuberculosis nor will the possessor of a flat chest find himself because of that advantage immune. It simply means as was shown by Dr Matz in a silicosis group that certain types are more susceptible to the disease. Environments being equal, were that possible, the individual with the flat better developed chest would probably be a little more resistant to the tubercle bacilli than the youngster or grown up having a deeper chest and a lower vital capacity. There was a question by Dr Emerson as to whether or not there are deep chested individuals in better environments. Certainly! These are only averages. However, predominant groups prevail in each district as to the incidence of tuberculosis. I thought I mentioned that there were much higher incidences of tuberculosis in cases reported from the deep-chest predominant districts. In reply to Dr Bakwin's question on certain groups I was careful to see that I measured a cross-sectional area of the city of Minneapolis. I tried to get schools from all sections to get a representative group. After I did all that work and compared the better with the poorer groups there was a definite

correlation. With regard to the racial groups, I took the nationalities when I measured some 19,000 children in a previous study and divided them into eleven racial groups. There was no appreciable difference in the chest contour of these various racial groups. It was only when the children were compared according to their environments that there was any difference in chest development. In adults of course, we have no way of finding whether they have been underdeveloped physically when they were youngsters, it is however very probable, but in the adult we found that a deep chest was the prevailing type among the tuberculous patients.

Clinical Notes, Suggestions and New Instruments

GONORRHEAL SEPSIS IN AN INFANT REPORT OF A CASE FOLLOWING OPHTHALMIA NEONATORUM

SAMUEL J. HOFFMAN, M.D. AND MAURICE SCHNEIDER, M.D.
CHICAGO

Numerous cases of gonorrheal septicemia have been reported in adults following genital infections with the gonococcus. In children such cases occur but are very unusual, being extremely rare in infants. Sepsis occurring as a result of gonorrheal ophthalmia is practically an unheard of condition.

The case here reported is of interest because of the unusual pathogenesis and the age of the patient.

REPORT OF CASE

A M., aged 4 days, was admitted to Cook County Hospital Feb. 24, 1937 from an outlying hospital. The birth was a precipitous one, the child being premature and weighing 5 pounds (2,268 Gm.). The eyes of the baby had been treated by the Crede method one hour after birth. Vaginal and cervical smears taken from the mother were negative for gonococci.

On examination there was noted a thick, yellow, purulent discharge from both eyes. The conjunctivae were swollen and reddened and smears taken from the pus showed gram-negative intracellular diplococci morphologically resembling gonococci. The diagnosis of gonorrheal ophthalmia was made by clinical appearance and positive smears.

Routine treatment consisted of irrigations of the eyes every thirty minutes with physiologic solution of sodium chloride. In addition three injections of boiled milk (1 cc.) were given for three days intramuscularly. The eyes cleared rapidly, but twelve days after admission the temperature became elevated and swellings were noted in both wrists. The swellings disappeared in eight days but new swellings appeared in both knees. Fluctuation became apparent and aspiration of the right knee yielded purulent fluid, but no gonococci were found on smear or by culture. Blood cultures taken at this time showed gonococci.

Examination of the blood revealed hemoglobin 49 per cent (Tallqvist), red blood cells 3,000,000 and white blood cells 12,500 of which 43 per cent were polymorphonuclear leukocytes and 57 per cent were lymphocytes. The Wassermann reaction was negative. Roentgenograms of the wrists and knees were reported negative.

Following the onset of the clinical gonorrheal arthritis the course was continually down grade. Death occurred April 4, when the infant was 43 days old. Prior to the end, the eyes were pronounced cured. Vaginal smears taken repeatedly were negative and no purulent discharge was noted from the vagina. Final clinical diagnosis was gonorrheal septicemia and arthritis.

Postmortem examination confirmed the clinical diagnosis.

Fluid taken from the right knee revealed gonococci culturally and morphologically.

In the spleen gonococci were found and diagnosed morphologically and culturally.

While parenchymatous degeneration of the myocardium was found the endocardium and valves were normal.

From the Department of Pediatrics of the University of Illinois College of Medicine and the Cook County Children's Hospital.

COMMENT

In reviewing the reported cases of gonococcemia, it is noted that in most cases ulcerative endocarditis occurred following a genital infection. In children all such cases followed a gonorrheal vaginitis. The clinical symptoms of a gonococcic septicemia differ in no essential features from sepsis due to other organisms. Of interest in this report are the facts that the child had received the Crede treatment and that all smears taken from the mother were negative for gonococci.

METHOD FOR REMOVAL OF A PLASTER CAST

MILTON H. PROSPERI, M.D., WASHINGTON, D. C.

The removal of a plaster cast, while a comparatively simple matter, is accompanied by difficulties that make the procedure at times very trying and vexatious.

Most cutters are designed to cut through the cotton and the plaster at the same time, but this is rather difficult to perform

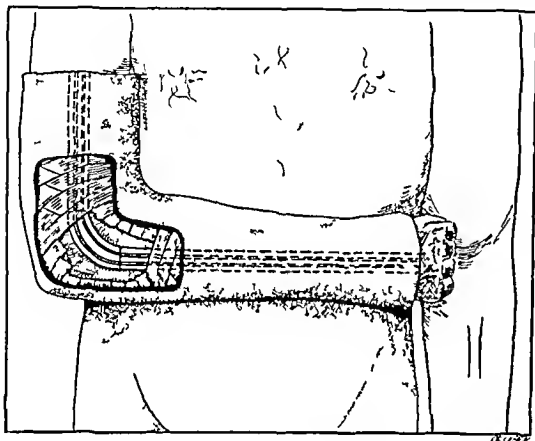

Fig 1—Course of metal channels

at one operation, being attended by considerable discomfort to the patient and at times causing traumatism to the skin as well. In view of these circumstances I have designed and used a

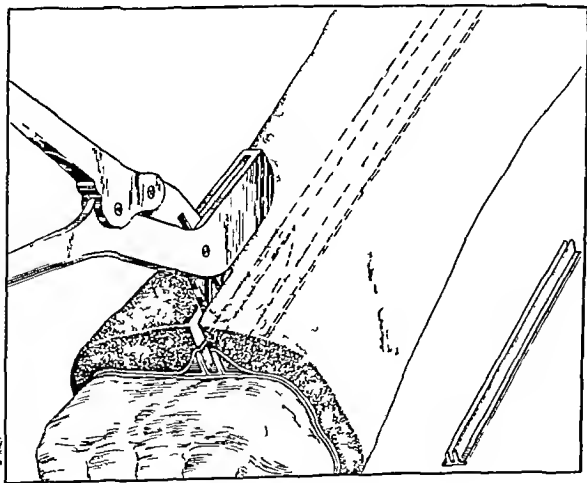

Fig 2—Method of cutting

method that facilitates the removal of a cast without undue difficulty and in a rapid and smooth manner and without injury to the patient.

This method consists of metal channels which are placed on top of the cotton or stockinet and held in place by two or three strips of adhesive tape, after which the plaster bandage is applied over them. The accompanying illustrations show the manner in which they are made and the position and method in which they are applied. As will be noted, the metal strips

contain a slot with a metal base, which allows the blade of the cutters to slide along in a free and easy manner, cutting through the plaster. Any one wishing to use a cast knife or any other instrument for removing a cast can do so with perfect ease, using as much pressure as desired without injury to the patient.

When it is desirable to use these channels in a cast which forms an angle such as at the knee or elbow joint or any other location, metal curves or arcs are provided which fit in the ends of the straight channels, forming a continuous groove, thus permitting the cutters to travel in one direction until the cast has been completely cut through. In cases of a full cast on the leg and thigh it is astonishing with what ease and rapidity a long cast of this kind can be removed, leaving smooth edges in case one wishes to tape them and reapply the cast.

Two or more channels may be applied to the same cast if necessary. They add to its strength and show only the slightest irregularity after completion. Also there is no need to cover the top of the groove with adhesive tape or other material as the plaster does not clog the groove. It is also necessary to wrap some of the plaster bandage over each end of the channel to prevent rubbing the skin, but this is a minor consideration as the cutters can be entered without difficulty.

These strips may be made of aluminum, are inexpensive and are not radiopaque, thereby causing no interference when it is desirable to make another exposure after the cast has been applied. They are indestructible, can be used indefinitely and certainly make of a tedious task an easy and satisfactory one.

GONOCOCCIC ARTHRITIS: PATHOGENESIS, MECHANISM OF RECOVERY AND TREATMENT

CLINICAL LECTURE AT ATLANTIC CITY SESSION

CHESTER S. KEEFER, M.D.

AND

WESLEY W. SPINK, M.D.

BOSTON

In an investigation of various types of arthritis, we have made detailed studies and observations on patients with gonococcic infections involving the joints. Particular interest has been taken in the pathogenesis of this disease, together with the mechanism of recovery. At this time we present a summary of the results of this study.

DIAGNOSTIC CRITERIA

The diagnosis of gonococcic arthritis was made on the following grounds: (1) a history of a recent attack of gonorrhea, (2) evidence of a localized gonococcal infection of the genital tract, (3) a positive reaction to the gonococcus complement fixation test on the blood and/or synovial fluid, and (4) the demonstration of gonococci in the synovial fluid.

CLINICAL FEATURES OF GONOCOCCIC ARTHRITIS

During the past five years, 140 cases of gonococcic arthritis have been observed and studied. Sixty-nine cases were summarized previously,¹ and we now add seventy-one more cases to this first group. A number of features aside from the arthritis deserve comment.

Read at the General Scientific Meetings at the Eighty-Eighth Annual Session of the American Medical Association, Atlantic City, N. J., 1937.

From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard), Boston City Hospital, and the Department of Medicine, Harvard University Medical School.
1. Myers, W. K., and Keefe, C. S. Gonococcal Arthritis. A Clinical Study of Sixty-Nine Cases. Ann. Int. Med. 8: 581 (Nov.) 1937.

Many of the outstanding characteristics of these cases are summarized in table 1. The course of events is usually as follows:

Subsequent to a gonococcic infection of the urethra or uterine cervix, less frequently of the conjunctiva or rectum, an acute polyarthritis appears. It is often abrupt in onset and is accompanied by all the signs of an intense inflammation involving periarticular tissues and synovial membrane. There are pain, redness and tenderness with limitation of motion. The process is more often polyarticular than monoarticular. The joints most frequently involved are the knees, ankles and wrists, although any joint of the body may be affected. There is often intense tenosynovitis about the wrists and ankles and in some instances the tendon sheaths are involved without any conclusive signs of associated arthritis. Tenosynovitis is much more common in patients with gonococcic arthritis than in patients with other types of arthritis and is a valuable diagnostic sign. The arthritis may be preceded by an infection of the respiratory tract, so that this feature may temporarily obscure or confuse the diagnosis. In most cases the arthritis begins within ten to twenty days after the onset of gonorrhea, however, we have seen cases of acute arthritis due to the gonococcus occur months or years after an attack of gonorrhea and, in some instances, after the original infection of the genito-urinary tract had healed entirely. In one case, acute arthritis followed a pelvic operation on a woman 65 years of age, and we were able to isolate the organisms from the synovial fluid. Smears and cultures from the cervix uteri were negative for the gonococcus, and no history of a localized genito-urinary infection could be elicited. In a few cases gonococcic arthritis is associated with pregnancy.

There are usually fever, leukocytosis and elevation of the corrected sedimentation rate. The process is most intense within the first few days of onset and does not tend to be migratory unless there is trauma to the local focus of infection in the genito-urinary tract. We have observed exacerbations of the arthritis after a vigorous prostatic massage as well as after reinfection. Frequently, after the acute onset the process becomes most conspicuous in one or more joints where the features of the infection are most intense.

The symptoms of the acute process persist for an indeterminate period, and many persons are disabled for several weeks or months.

Accompanying the acute process in the joints and tendon sheaths there is rapid wasting of the muscles supporting the affected joints. Histologic examination of muscle in the immediate neighborhood of the joints has failed to reveal evidence of acute inflammation.

Demonstrable bacteremia is unusual unless there is associated endocarditis. We have observed three cases of bacteremia without endocarditis, and certain of the features are worthy of comment. One of the striking features is the cutaneous eruption. It is maculopapular, and in some areas it is hemorrhagic and rapidly becomes vesicular and then pustular. The eruption is most intense over the extremities but appears on the trunk as well. In one of our cases it was accompanied by hepatomegaly, splenomegaly, jaundice and thrombopenia. Another clinical feature, in a second patient, was a tendency for the fever to show periodic exacerbations every forty-eight hours. In the third case with bacteremia the blood stream was cleared of organisms after the injection of specific antigonococcic immune

horse serum (Parke-Davis). We have not observed a cutaneous eruption of the character mentioned without bacteremia.

The ocular signs of the infection are most interesting and important, since they aid in diagnosis, and when there is iridocyclitis add to the seriousness of the disease. The commonest is metastatic catarrhal conjunctivitis, which occurs in from 10 to 20 per cent of the cases. In common with other observers, we have found that the exudate from the conjunctivae in these cases is sterile and may appear at the same time as the arthritis or precede it. Conjunctivitis often disappeared before the arthritis and caused no permanent damage. It is more common in persons who have a sterile than an infected effusion into the joints. Iridocyclitis is a much more serious complication, since it may lead to permanent impairment of vision.

TABLE 1—Summary of Clinical Features in 140 Cases of Gonococcic Arthritis

1 Sex—Males	104	
Females	36	
2 Polyarthritis	107	
Monoarthritis	33

Pregnancy		4
Bacteremia		5
Recovered	3	
Died	2	
Endocarditis		2
Keratoderma blennorrhagicum		4
Sterile meningitis		1

A rare form of cutaneous eruption accompanying this infection is keratoderma blennorrhagicum, of which we have seen four cases. The characteristic lesion is most prominent on the plantar surfaces of the feet. There is thickening of the skin, with the edges of the lesion showing a sharp line of demarcation. Toward the center of the lesion there may be necrosis and sloughing, which gives a "relief map" appearance. The skin between the toes may be thickened, moist and adherent. Similar lesions may be seen on the arms and legs. These are firm, reddened, raised and waxy looking. Other lesions are scalp and simulate psoriasis.

A combination of arthritis and conjunctivitis, or arthritis and the cutaneous eruption of keratoderma, is always suggestive of gonococcic infection. While it is true that conjunctivitis is an associated feature of postdysenteric arthritis and in rare instances of rheumatic fever, it is more common with gonococcic infection.

A rare complication in the absence of endocarditis is acute hemorrhagic glomerulonephritis,² of which we have seen two cases. All the features of hemorrhagic nephritis are present, and in our one case with necropsy the lesions in the kidney were those of sterile diffuse glomerulonephritis.

One may say then that acute polyarthritis associated with tenosynovitis, a history of gonococcic infection, conjunctivitis or iridocyclitis, and a cutaneous eruption resembling psoriasis are always suggestive of gonococcic arthritis.

THE PATHOLOGIC FEATURES OF GONOCOCCIC ARTHRITIS

Keefer, Parker and Myers³ have examined the knee joints of two patients who had active gonococcic arthritis at the time of death. The first patient had a sterile synovial fluid, and no gonococci were recovered from the joints at necropsy. No organisms could be observed in the stained sections. In a second case gonococci were grown from the synovial fluid, and they were observed with ease in the stained section of the synovial membrane. These cases represented what is so often seen in clinical practice, namely, a type of arthritis associated with gonococcic infection and a sterile synovial fluid and a second type, in which the synovial fluid is infected. In the case in which the organisms were observed, the synovial membrane had been completely destroyed and replaced by granulation tissue containing numerous lymphocytes, polymorphonuclear leukocytes, macrophages and plasma cells. In the deeper layers of the synovia there was a perivascular infiltration of lymphocytes. The sections stained for bacteria showed numerous gram-negative cocci which were identified as gonococci, since this organism had been recovered from the tissues by cultural methods. There was little change in the cartilage overlying the articular surface.

Examination of the synovial membrane from the knee joint in which gonococci were demonstrated showed a proliferation of the synovial membrane, with increase in thickness and collections of polymorphonuclear leukocytes. In the subsynovial tissue layer or connective tissue layer there was a marked infiltration with polymorphonuclear leukocytes, lymphocytes and macrophages, with intense congestion of the blood vessels. An occasional macrophage filled with blood pigment was seen. In several foci there was a partial loss of the superficial synovial cells, with a deposit of fibrinous thrombi. In places the collagen and polymorphonuclear leukocytes appeared necrotic. A careful search of the tissue stained for bacteria failed to reveal their presence.

It would appear that the inflammatory lesions in the synovial membrane in patients with sterile synovial fluid are much less intense than in those with infected fluid. In the former the surface layer of the synovia remains intact and shows no areas of destruction, while in the latter there is complete destruction of the synovial lining, with replacement by granulation tissue. In the one case the conspicuous lesions are beneath the surface of the synovia, whereas in the other they extend to the surface and produce complete destruction of the superficial cells.

Destruction of the articular cartilage varies considerably in different cases of gonococcic arthritis,

depending apparently on the joints involved. It is most pronounced in the wrist and phalangeal joints, the hip and the ankle joints. It is less conspicuous in the knee joints. This may be accounted for in part by the fact that in the knee joint large amounts of fluid collect, whereas in the other joints mentioned there are a great many white blood cells and relatively small amounts of synovial fluid. Studies on the antitryptic content of synovial fluid and the tryptic activity of white blood cells in digesting cartilage suggest that the articular cartilage in the knee joint is protected in many cases by the presence of a large effusion of fluid which contains antitryptic substances. When the exudate is thick and purulent and contains a relatively large number of leukocytes and a relatively small amount of synovial fluid, the opportunities for the destruction of cartilage are great.

Ankylosis of joints associated with gonococcic arthritis is due to periarticular fibrosis or adhesions between the articular cartilage. In the case of the knee joint, stiffness and limitation of motion are often due to adhesions between the patella and the femur. True bony ankylosis is rare except when the wrist joints are involved.

TABLE 2—Summary of 114 Samples of Synovial Fluid from Eighty-Three Patients with Gonococcic Arthritis

	Per Cent	Total Number of Cells per Cu. Mm.	Differential Cell Count per Cent					Chemical Examination			
			Polymorphonuclears	Lymphocytes	Monocytes	Granulocytes	Eosinophils	Total Protein Gm per 100 Cc.	Sugar Mg per 100 Cc.	Nonprotein Nitrogen, mg per 100 Cc.	Other

CHARACTERISTICS OF THE SYNOVIAL FLUID

Several years ago the characteristics of the synovial fluid of forty-one patients with gonococcic arthritis were defined.⁴ Since then, additional information has been obtained from forty-two patients. In all, we have examined 114 samples of synovial fluid from eighty-three patients. The results are summarized in table 2 and may be commented on in further detail.

For analysis of results, the data were separated into those on samples of infected fluid and those on samples of sterile fluid. There were differences in the characteristics of these two types of fluid quite independent of the presence or absence of bacteria. In general, the total cell count is likely to be higher, with more polymorphonuclear cells, in the infected fluids than in the sterile ones. The total protein content is that of an exudate in both types, and the nonprotein nitrogen is the same as in the blood. The sugar content in infected synovial fluids is lower than that of the blood, whereas in sterile effusions it is the same.

BACTERIOLOGY OF THE SYNOVIAL FLUID

The synovial fluid of seventy-eight patients was cultured immediately on withdrawal from the synovial cavities. The gonococcus was recovered from the fluid

⁴ Keefer, C. S., Myers, W. K. and Holmes, W. F., Jr. Characteristics of Synovial Fluid in Gonococcal Arthritis. *J. Clin. Invest.* 13: 767 (Dec.) 1934.

in only 26 per cent of the seventy-eight cases. All the cultures were carried out in an anaerobic jar. This method has been much more efficient in detecting the presence of organisms than the use of stained smears. We have been able to cultivate organisms from the synovial fluid when they were not observed on smear preparations, and we have never failed to cultivate them if they were seen on a stained smear. To explain the relatively small number of cases in which cultures were positive, we studied the various serologic reactions in the synovial fluid to determine whether antibodies bactericidal for the gonococcus could be detected.

SEROLOGIC REACTIONS OF THE SYNOVIAL FLUID

Gonococcus Complement Fixation Test—The reaction to the gonococcus complement fixation test is positive in about 66 per cent of the cases of gonococcal arthritis when the test is carried out on the synovial fluid. It is higher in patients with sterile effusion than in those with infected fluid. A positive complement fixation reaction of the synovial fluid was never seen without a positive reaction of the blood serum.

Bactericidal Action of the Synovial Fluid—When the bactericidal action of the synovial fluid was examined it was found that no bactericidal antibodies were present in infected fluid, and the bactericidal power of the whole blood was low or only moderately elevated. In the sterile synovial fluid one could invariably detect antibacterial antibodies, and either the synovial fluid and blood showed the same bactericidal action or the fluid showed less bactericidal action than the blood. Synovial fluid obtained from patients with nongonococcal arthritis was not bactericidal for the gonococcus. Such observations suggest that the reason for the relatively large number of examples of sterile synovial fluid in cases of gonococcal arthritis is the presence of a relatively high titer of specific antibody.

When specific antigenococcal immune serum was added to synovial fluid *in vitro*, bactericidal action was enhanced, so that there seemed to be little doubt that the bactericidal power of the synovial fluid was due to the presence of antibodies.

Antitryptic Substances in Synovial Fluid—The destruction of cartilage accompanying various forms of arthritis varies considerably, and it is probably due in part to the balance existing between the ferments of the leukocytes plus the infecting organisms and the antiferment substances in the synovial fluid. From experiments recorded elsewhere,⁵ it was concluded that synovial fluid contains substances which are capable of inhibiting tryptic digestion. When large numbers of white blood cells were present, particularly polymorphonuclear leukocytes, the antitryptic power was usually reduced. The synovial fluid from patients with gonococcal arthritis was capable of inhibiting the digestion of cartilage by leukocytic autolysates. It appears that the presence of large amounts of antitryptic substances in the synovial fluid prevented or at least limited the destruction of articular cartilage by the enzymes liberated in the purulent exudates. These observations are consistent with what one sees clinically, namely, that the destruction of cartilage in cases of gonococcal arthritis occurs in the joints which contain a thick purulent exudate and is unusual in other joints when the cell content is low and the amount of fluid is relatively large.

EFFECT OF MUCIN ON THE BACTERICIDAL ACTIVITY OF SYNOVIAL FLUID

One of the problems of considerable interest and importance is to determine the factors responsible for the localization of gonococci in the joints. From clinical observations it is evident that the gonococcus localizes and survives in areas which are supplied by large amounts of mucin, that is, the urethra, cervix, uteri, conjunctiva and joints. This suggested that perhaps mucin was a favorable medium for the growth of the gonococcus or possibly provided an environment that aided the gonococcus in surviving. Our studies indicate that the presence of mucin in synovial fluid assists some strains of gonococci in surviving, especially when the antibody content of the fluid is low. When the antibody content is high it continues to be operative in spite of the presence of mucin.

SEROLOGIC REACTIONS IN THE BLOOD

Bactericidal Tests—The gonococcus has only rarely been isolated from the circulating blood of patients with gonococcal arthritis. We have observed three such

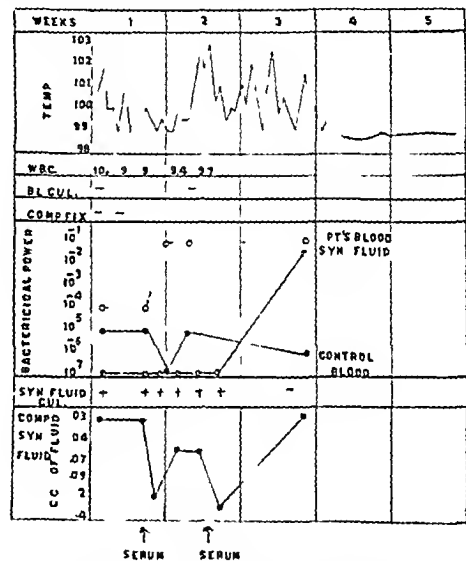

Chart 1—The course of a case of gonococcal arthritis with infected synovial fluid. The arrows indicate the time of injection of 30 cc of antigenococcal horse serum into the knee joint. The temperature curve indicates the highest and lowest daily temperatures. The white blood count is recorded in thousands. The complement titer of the synovial fluid is recorded in cubic centimeters. The bactericidal power is the total number of organisms killed in 0.5 cc of the patient's blood or synovial fluid. 10^5 dilution contained four organisms.

cases. In these cases it was not possible to demonstrate antibacterial antibodies in the circulating blood while organisms were present. When the organisms disappeared spontaneously from the circulating blood in one case, antibodies made their appearance. In another case⁶ the blood was cleared of bacteria after the injection of antigenococcal immune serum, and there followed an increase in the bactericidal power of the blood. It would appear that the absence of bacteremia in most cases of gonococcal infection may be explained on a basis of the antibody content of the blood or an efficient local defense mechanism in the urethra and elsewhere. The bactericidal action of the whole blood has been studied in patients with urethritis and in those with arthritis and the results recorded elsewhere.⁷ It

7. Spink W. W. and Keefe C. S. Studies of Gonococcal Infection II. The Bactericidal Power of the Whole Dehematized Blood of Patients with Gonococcal Arthritis. *J. Clin. Investigation* 16: 17 (March) 1937.

5. Holmes W. F. Jr., Myers W. H. and Keefe C. S. The Inhibition of Tryptic Digestion of Cartilage by Synovial Fluid from Patients with Various Types of Arthritis. *J. Clin. Investigation* 14: 131 (Jan.) 1935.

was found that the bactericidal action of whole defibrinated blood for the gonococcus in vitro depended on the combined action of antibody and complement, and this could be demonstrated without the presence of cells. It was also noted that the bacteriolytic titer of the blood of patients with gonococcic arthritis increased during the course of the disease. In patients with gonococcic urethritis, antibodies could be detected as the disease progressed. In some of the patients with urethritis the presence of antibodies in the circulating blood was shown not to prevent the local infection from persisting or spreading, and many strains of the organisms capable of producing urethritis could be killed in considerable numbers by the blood of normal controls. There is evidence then that the localization of organisms in the joints is due in part to an efficient clearing mechanism of the blood and that this efficiency is partly the result of the development of antibodies to the specific organism.

Gonococcus Complement Fixation Test on Blood—One test of considerable value in the diagnosis is the gonococcus complement fixation test. Several years ago Myers and Keefer⁸ reported the results of this test on the blood and the synovial fluid of forty-one patients with gonococcic arthritis. Then, as now (forty-two additional cases), we found that the reaction is positive in about 85 per cent of cases of gonococcic arthritis.

COMMENT

It may be stated then that during the course of gonococcic infection antibodies appear in the circulating blood. These antibodies may be an indication of a response on the part of the host to the infection and are probably largely responsible for the localized infection and recovery of the patient. After the development of specific antibodies of a sufficiently high titer to kill the infecting organism, the process of repair proceeds in the joints. This course of events is illustrated in chart 1.

A number of features of the disease continue to remain obscure. For example, why do the patients show a latent period between the development of the local infection and the arthritis? What is the mechanism involved in the development of the bilateral catarrhal metastatic conjunctivitis? Why do patients have recurrent effusions into the joints of sterile fluid of high antibody titer? These questions require an answer, and when their explanation becomes clear more information will be available for an understanding of the pathogenesis of the disease.

TREATMENT OF GONOCOCCIC ARTHRITIS

The main objective in treating gonococcic arthritis is to remove the cause, give relief from symptoms and restore normal function to the joints. Methods of treatment which aim to destroy the organisms are naturally the most promising so far as complete recovery is concerned. To accomplish destruction of the organisms three general methods have been used: (1) specific serum therapy, (2) fever therapy and (3) chemotherapy.

Specific serum therapy has not been very successful in the treatment of gonococcic arthritis. We have been able to clear the circulating blood of organisms in cases of bacteremia but in several cases in which serum has been injected directly into the joint cavities the results

have not been successful. It would appear that serum therapy should be limited to cases of bacteremia.

Within the past few years considerable interest has been shown in fever therapy of gonococcic arthritis. The main objective of this form of treatment is to increase the body temperature to such a level that the organisms are killed. The treatment has had an enthusiastic reception, and a number of reviews are now available.⁹ There seems to be almost universal agreement that it is effective in a high percentage of cases in which the disease is acute. Its effect is less striking in cases of chronic and long standing disease.

More recently there has been a revival of chemotherapy in the treatment of gonococcic infection, and our experience with the use of sulfanilamide in the treatment of local infections of the genito-urinary tract and arthritis is worth mentioning. We have treated three patients with gonococcic arthritis with this drug. In two the synovial fluid was infected, in the third it was sterile. In the two patients with an infected fluid,

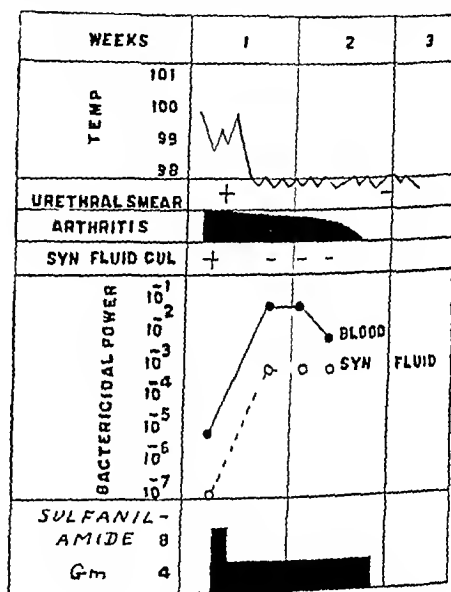

Chart 2—The course of gonococcic infection following treatment with sulfanilamide.

the synovial fluid was sterilized within two days after the drug was given, and the organisms could not be obtained from the local lesions in the genito-urinary tract. Chart 2 illustrates the course of the changes in the cultures and in the bactericidal content of the blood and the synovial fluid in one of these cases. We have not been able to sterilize the synovial fluid in other cases with other forms of treatment within such a short period. This form of treatment deserves a thorough and critical investigation.

Our plan of treatment has varied with individual cases. We have made it a rule to aspirate all joints showing an increase in the synovial fluid. Studies of the fluids may provide one with information regarding diagnosis, prognosis and further treatment. The patients who had a sterile synovial fluid with a total cell count of less than 40,000 usually did much better than far as the ultimate outcome was concerned. When the fluid

A., Ghris, J. H., Francis, and White, T. P. The Problem of Rheumatism and Arthritis. Review of American and English Literature for 1933. Ann. N. Y. A. 10: 754 (Dec.) 1936.

was infected and contained large amounts of mucin and fibrin, so that aspiration was difficult, the joints were opened and irrigated through a small incision in the capsule. After the joint was washed out, it was closed tightly and placed in traction, and motion was started as soon as it was possible without pain or discomfort. We repeat that it has been desirable to limit this form of treatment to patients showing a thick, fibrinous, infected fluid.

GENERAL TREATMENT

As this disease is likely to be protracted, the patients present the clinical picture which is so common with chronic infections. They often lose weight and have anemia, and the muscles about the affected joints atrophy. Attempts are therefore made to provide a liberal intake of food, to treat the anemia with iron and/or blood transfusions and to treat the patient symptomatically for the relief of his pain and discomfort.

The convalescence is often a difficult stage to manage, since it is frequently prolonged over a period of some weeks. The following procedures should be carried out: (1) Efforts should be made to reestablish muscle tone about the affected joints through active and passive motion exercises, (2) the arches of the feet should be given support if the patient has been confined to bed for a long period, and (3) instructions should be given regarding prophylaxis against venereal disease.

In general, it may be said that the patients who do well are those with a sterile effusion into the joints and that those who do badly are those with infected synovial fluid. It is noticeable that patients with involvement of the wrist and hip joints do not recover so completely as those who have only the knee joint affected.

SUMMARY AND CONCLUSIONS

A study of 140 cases of gonococcal arthritis leads to the following statements:

1 Gonorrhea is a frequent cause of acute polyarthritis, and, while any joint may be affected, gonococcal arthritis is most often seen in the knees, wrists and ankles.

2 Associated lesions, such as tenosynovitis, bilateral metastatic catarrhal conjunctivitis, iridocyclitis and keratoderma blennorrhagicum, are helpful clinical aids in the diagnosis.

3 The pathologic lesions in the joints begin in the periarticular tissues and synovial membrane, and involvement of the cartilage is secondary. Destruction of cartilage is most conspicuous in the wrist, hip and finger joints. Bony ankylosis is rare except in the wrist joints. Fibrous ankylosis is more common.

4 Examination of the synovial fluid is helpful in diagnosis. Organisms were isolated in 26 per cent of the cases. The fluid had all the characteristics of an exudate. The average total cell count was higher for the infected fluid than for the sterile fluid.

5 *Gonococcus* complement fixation and bacteriolytic antibodies diffuse into the synovial cavities.

6 The antibody content of synovial fluid is the same or slightly less than that of the blood when the fluid is sterile. When it is infected, antibodies are not demonstrated.

7 The synovial fluid contains antitryptic substances which probably protect the cartilage from destruction by the tryptic-like ferments of the leukocytes.

8 The *Gonococcus* complement fixation test on the blood gave a positive reaction in 86 per cent of the

cases. The percentage of positive reactions was somewhat lower for tests on the synovial fluid, especially when the fluid was infected.

9 The mucin in synovial fluid interferes with the destruction of organisms when the antibody titer is low. When the antibody titer rises, there is no apparent depression of the activity of the fluid.

10 The blood plasma of patients with gonococcal infections is actively bactericidal for the homologous strain of infecting organism. The bactericidal activity increases during the course of the disease.

11 There is suggestive evidence that recovery from gonococcal arthritis is associated with the development of increased resistance to the invading organism.

12 There are various types of treatment. There is evidence that sulfamidamide is bactericidal for the gonococcus when it is added to blood serum. In two patients with infected synovial fluid the gonococci disappeared from the fluid within two days after this drug was administered. This type of treatment deserves further study and investigation.

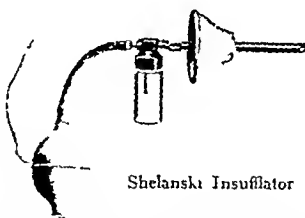

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
HOWARD A. CARTER, Secretary

SHELANSKI INSUFFLATOR ACCEPTABLE

Manufacturer: John Wyeth & Brother, Inc., Philadelphia

This device is used for insufflating the vagina with silver picrate powder in the treatment of *Trichomonas vaginalis* vaginitis. The powder has been accepted for this purpose by the Council on Pharmacy and Chemistry (*THE JOURNAL*, July 3 1937, p. 29). In appearance, the instrument is similar to an atomizer. A rubber bulb and orifice guard are attachable to a brass stem, chrome-plated over a subcoating of nickel. The medicated powder, in a vial with a thread top, can be screwed

Shelanski Insufflator

directly onto the Insufflator. The unit is simple in construction and readily sterilized. It is not patented, nor is it sold under any trade mark. The firm name "Wyeth" is imprinted on it.

According to the firm, the instrument makes possible a thorough dispersion of the medicated powder by permitting mild distention of the vaginal walls so that folds and crevices become accessible to the medicament. The firm submitted evidence from a reliable investigator to support the therapeutic claims made for the Insufflator in the form of a report on 100 cases treated with this instrument and a silver picrate kaolin powder.

In all these cases the diagnosis of *Trichomonas vaginalis* vaginitis was made. Sixty-two cases were observed for six months and thirty-eight for nine months.

The following treatment procedure was employed. The patient was placed in a lithotomy position and 5 Gm. of silver picrate-kaolin powder was blown into the vagina by means of the Insufflator, care being taken to use only enough pressure to balloon out the vaginal walls. The patient was also given six vaginal suppositories of silver picrate, one to be used each night, and she was instructed to return in one week. At this time a smear was taken and the foregoing treatment repeated. The patients were examined for *Trichomonas* seven and fourteen days after the original insufflation, and also at the end of each menstrual period for the next six to nine months. Cultures of the vaginal secretion were made each time.

There were three recurrences in this group occurring at the fifteenth, eighteenth and twenty-first week after the original treatment in three patients. Two of these were again treated

and remained negative up to their last appearance at the clinic, at the seventeenth and twenty-second week following the second course of treatment. At the end of the two week period of treatments it was found that the discharge disappeared in 90 per cent, the itching in 94 per cent and the burning in 96 per cent of the 100 patients, and smears and cultures were negative in 100 per cent.

The firm's investigator reported that the percentage of cases receiving symptomatic relief was high and recommended the instrument for this reason as well as because of the simplicity with which it operates. The incidence of recurrence is low with this type of treatment, according to the report.

An investigator was appointed by the Council to use the unit in his office practice in treating gynecologic diseases. He reported that it was satisfactory for the purpose for which it was intended.

In view of the foregoing report, the Council on Physical Therapy voted to include the Shelanski Insufflator in its list of accepted devices.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
PAUL NICHOLAS LEECH Secretary

THE USE OF HYDROQUINONE AS A "STABILIZING" AGENT IN PREPARATIONS CONTAINING VITAMIN A

Edible oils are known to take up atmospheric oxygen at a comparatively slow rate over a period of time, called the induction period, and then undergo rather extensive chemical change with rapid uptake of oxygen. Vitamin A is susceptible to oxidation and it has been shown that certain measures which are effective in the retardation of oxidation of a vitamin A-containing oil tend to preserve vitamin A. For some time it has been known that the use of small amounts of hydroquinone will extend the induction period of an oil. Certain firms marketing accepted brands of fish liver oils have used this drug as an antioxidant and in some cases the use of it has been so emphasized in the promotion of the product that it might well have given rise to the assumption that the vitamin A content of the preparation concerned was "stable" under conditions of ordinary use. The Council questioned this assumption and questioned indeed the evidence for the necessity of the addition of hydroquinone to these products. The Council asked manufacturers of accepted products to submit evidence that the addition of hydroquinone is a necessity for the proper preservation of cod or halibut liver oils under conditions of ordinary usage.

In this connection attention was called to the possible harmfulness of the ingestion of hydroquinone, but after investigation the Council held that the available evidence does not indicate that the amount of hydroquinone likely to be ingested with the vitamin-containing oils to which it may be added would be injurious. At the present time it may be stated that there is no concrete evidence indicating injury from ingestion of such oils as marketed, containing hydroquinone. Attention was called, on the other hand, to the fact that it is equally true that no data are available excluding this possibility following the use of such materials over long periods of time.

In the Council's discussion it was brought out that, if the addition of hydroquinone to halibut liver oil is approved, it will furnish an undesirable precedent for the use of a number of antioxidants in a wide variety of pharmaceutical products. The Council is informed that the meat inspection regulations of the Department of Agriculture prohibit the addition to meat and food products of preservatives or chemicals designated as antioxidants.

The Council considered the evidence submitted by the firms for or against the use of hydroquinone as a stabilizing agent in fish oils and came to the conclusion that they had failed to

demonstrate that under ordinary conditions of use the loss of vitamin A from halibut liver oil or cod liver oil is excessive. The Council therefore voted disapproval of the use of hydroquinone as an antioxidant in vitamin preparations and recommended further that in the light of present day evidence no accepted vitamin preparation may retain that status if such antioxidant is used.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS ADDING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES OF WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH Secretary

SULFANILAMIDE (See THE JOURNAL, July 31, 1937, p. 358, and Supplement to N. N. R., p. 17)

The following revision of the published description, extending the allowable claims, has been adopted:

Actions and Uses—Originally it was reported that sulfanilamide acts against Lancefield's group A strains of hemolytic streptococcus by virtue of an apparently specific effect on these organisms. More recent clinical evidence suggests that the action of this chemical may affect other organisms, especially certain gram-negative cocci. The evidence suggests that its action may be antibacterial.

Sulfanilamide has been used primarily in infections due to beta-hemolytic streptococci, especially in the treatment of puerperal fever, erysipelas, hemolytic streptococcus septicemia, streptococcal sore throat and surgical infections with hemolytic streptococcus. Present studies indicate that this drug is useful in the treatment of gonococcal infections. In some cases the results have been most striking, while in others the drug has not proved especially efficacious. In this connection it is well to note that the reactions following the administration of the drug are at least occasionally of a serious nature (see below). It has also been used in the treatment of gonorrheal vulvovaginitis in young girls but recovery from the condition has not been permanent with this agent. The literature also indicated usefulness in meningococcal infections and possibly gas bacillus infections. It must be remembered however that because of the extensive application of this relatively new therapeutic agent its use in these conditions requires caution and careful observation. This is especially true in view of the reactions which are discussed in the following paragraphs. The evidence is incomplete at the present time for further consideration of the possible usefulness of this drug in infections by *Bacterium coli*, *Bacterium typhosum*, and paratyphosum A and B, as well as all varieties of *Brucella*. There is some indication that it is useful in pneumonia due to type III pneumococci.

It must be remembered that acidosis sometimes follows the administration of sulfanilamide. It has been suggested that sodium bicarbonate may prove useful in combating the acidosis produced by the drug. Jaundice and urticaria have also been reported as undesirable side effects following the administration of this drug. Magnesium sulfate should not be administered during the course of the treatment because it is thought to increase the danger of acidosis. Statements concerning the effectiveness of sulfanilamide in the treatment of gonorrhea have appeared in the public press. Unfortunately the laity has been able to obtain the drug for this purpose over the drug counters and sulfhemoglobinemia and cyanosis have followed this uncontrolled use in certain instances. There is also a possibility that methemoglobinemia and granulocytopenia may follow low such therapy and there have been reports of hemolytic anemia following the administration of sulfanilamide. It is advisable in the use of sulfanilamide to examine the blood microscopically for evidence of red blood cell destruction as well as lowering of the white blood cell count, and to rule out both sulfhemoglobinemia and methemoglobinemia by spectroscopic examination of the blood. Until more is known it should not be prescribed concurrently with other drugs (except in case of sodium bicarbonate as indicated above).

POLLEN ALLERGEN SOLUTIONS SQUIBB (See New and Nonofficial Remedies, 1937, p. 36)

The following preparations are also marketed in 5 cc. ampuls representing 25,000 protein nitrogen units per cubic centimeter:

Grasses Combined Pollen Allergen Solution Squibb (Berberis, 6 cc. 11 June Grass Orchard Grass Red Top and Timothy in equal parts) Fescue Combined Pollen Allergen Solution Squibb (Giant Fescue and Dwarf Rye-grass in equal parts)

Council on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED

FRANKLIN C BING Secretary

WEGNER BRAND TOMATO JUICE

Manufacturer—Wegner Canning Corporation, Sodus N Y

Description—Canned tomato juice seasoned with salt

Manufacture—Carefully inspected tomatoes are washed, scalded, again washed and trimmed of stems, cores and any defects. The cleaned tomatoes are preheated and gently pressed to separate the juice from the core, seeds and skin. Salt is added. The juice is heated and automatically packed in cans which are sealed, processed and cooled.

Analysis (submitted by manufacturer)—Moisture 92.6%, total solids 7.4%, ash 1.2%, fat (ether extract) 0.04%, protein (N \times 6.25) 0.9%, total reducing sugars as invert sugar before inversion 3.8%, total reducing sugars as invert sugar after inversion 3.8%, crude fiber 0.2%, carbohydrates other than crude fiber (by difference) 5.1%.

Calories—0.24 per gram, 7 per ounce

Vitamin—Chemical titration of cevitamic (ascorbic) acid in the canned tomato juice shows 0.21 mg per cubic centimeter, or 129 International units of vitamin C per fluidounce.

CHOC-LADE CHOCOLATE FLAVORED DRINK

Bottler and Distributor—Bowman Dairy Company, Chicago

Description—Pasteurized chocolate flavored sweetened defatted milk (defatted milk with added cocoa, starch-free powdered cane sugar, with vegetable emulsifying agent, salt and vanilla flavoring).

Manufacture—Choc-Lade Dairy Drink Powder (THE JOURNAL, July 24, 1937, p 277) is mixed with an equal amount of sugar and part of the milk, and agitated until smooth. Remaining milk and sugar are added to mixture, heated in vats 63-66 C for thirty minutes with constant agitation, cooled, bottled and kept refrigerated until delivery.

Analysis (submitted by manufacturer)—Moisture 82.5%, ash 0.7%, fat (ether extract) 2%, protein (N \times 6.25) 2.3%, reducing sugars as invert sugar 2.6%, reducing sugars as lactose 5.1%, sucrose (copper reduction method) 2.9%, crude fiber 0.1%, carbohydrates other than crude fiber (by difference) 12.4%, caffeine and theobromine 0.01%.

Calories—0.76 per gram, 22 per ounce

Vitamin—The vitamin content of Choc-Lade is that of the milk used.

- (1) MACMARR BRAND EVAPORATED MILK
- (2) MAX-I-MUM BRAND EVAPORATED MILK
- (3) SUNNY SKIES BRAND EVAPORATED MILK

Distributors—(1) Lucerne Cream and Butter Company, Oakland, Calif., (2) Safeway Stores of California, (3) General Food Products Company, Vernon, Calif.

Packers (1) and (3)—Lucerne Cream and Butter Company, Oakland, Calif. (2) Lucerne Cream and Butter Company, Oakland, Calif. Carnation Company, Milwaukee, Nestle's Milk Products, Inc., New York, Pet Milk Company, St. Louis.

Description—Unsweetened sterilized evaporated milk.

Manufacture—Milk from company and government inspected farms is tested, preheated, evaporated under vacuum, homogenized, cooled, standardized to meet government requirements for butter-fat and total solids, filled into cans, sealed and sterilized.

Analysis (submitted by manufacturer)—Moisture 74.0%, total solids 26.0%, ash 1.5%, fat (ether extract) 7.9%, protein (N \times 6.38) 7.1%, lactose (by difference) 9.5%.

Calories—1.4 per gram, 40 per ounce

QUAKER MAID BRAND TABLE SYRUP

Manufacturer—Atlantic Syrup Refining Company, Philadelphia

Description—Mixture of definite proportions of corn syrup and refiners' cane syrup.

Manufacture—Eighty per cent corn syrup unmixed and 20 per cent refiners' cane syrup are mixed and filled into cans at 82 C.

Analysis (submitted by manufacturer)—Moisture 24.0%, total solids 76.0%, ash 0.6%, fat (ether extract) none, protein (N \times 6.25) 0.1%, reducing sugars as invert sugars 34.9%, reducing sugars as invert sugars after invertase inversion 46.2%, sucrose (estimated) 10.7%, dextrins (by difference) 29.7%, sulfur dioxide 0.001%.

Calories—3.0 per gram, 85 per ounce

WHITE HOUSE BRAND SWEETENED CONDENSED MILK

Distributor—The Great Atlantic & Pacific Tea Company, New York

Manufacturer—The Quaker Maid Company, Inc., New York

Description—Sweetened condensed milk prepared from milk and sucrose.

Manufacture—Fresh milk, tested in the company's plant, is cooled, drawn into a hotwell and sucrose is added. The mixture is concentrated under vacuum, cooled and sealed in cans.

Analysis (submitted by manufacturer)—Moisture 28.5%, total solids 71.5%, ash 1.5%, fat (ether extract) 8.35%, protein (N \times 6.38) 8.6%, sucrose 42.9%, lactose 11.8%, carbohydrates (by difference) 53.0%.

Calories—3.2 per gram, 91 per ounce

CREAM ROLLER EXTRACT FLOUR, PHOSPHATE ADDED

HENRY CLAY ROLLER EXTRACT FLOUR, PHOSPHATE ADDED

J E M BEST PATENT FLOUR, PHOSPHATE ADDED

Manufacturer—Lexington Roller Mills Company, Lexington, Ky.

Description—Soft red winter wheat "short patent" flours with 0.5 per cent added calcium acid phosphate, bleached.

Manufacture—Selected soft red winter wheat is cleaned, washed, scoured, tempered and milled by essentially the same procedure as described in THE JOURNAL, June 18, 1932, page 2210. Chosen flour streams are blended and bleached with nitrogen trichloride (one ninth ounce per 196 pounds) and with a mixture of benzoyl peroxide and calcium phosphate (one-fourth ounce per 196 pounds), 0.5 per cent calcium acid phosphate is added. The products are 40 per cent patent flours.

Analysis (submitted by manufacturer)—Moisture 12.0%, ash 0.8%, fat (ether extract) 1.2%, protein (N \times 5.7) 8.3%, crude fiber 0.2%, carbohydrates other than crude fiber (by difference) 77.5%.

Calories—3.54 per gram, 101 per ounce

SUNLIGHT BRAND OLEOMARGARINE

Manufacturer—The Cudahy Packing Company, Chicago

Description—Margarine prepared from hydrogenated cottonseed oil, pasteurized cultured skimmed milk and salt, and containing 0.1 per cent of sodium benzoate.

Manufacture—Pasteurized cultured skimmed milk to which has been added salt and sodium benzoate, is added to hydrogenated cottonseed oil, and the mixture is whipped. The resulting emulsion is solidified by chilling, then kneaded, refrigerated, molded into prints and automatically wrapped and packed in cartons.

Analysis (submitted by manufacturer)—Moisture 14.0%, total solids 86.0%, ash 2.7%, sodium chloride 2.6%, fat (ether extract) 81.5%, protein (N \times 6.25) 0.8%, carbohydrates (by difference) 1.0%.

Calories—7.4 per gram, 210 per ounce

SATURDAY, OCTOBER 30, 1937

DEATHS FOLLOWING ELIXIR OF SULF- ANILAMIDE-MASSENGILL—II

Nine deaths following the administration of Elixir of Sulfanilamide-Massengill were reported as THE JOURNAL went to press last week. By October 25 the number had risen to forty-six, with additional cases not yet fully confirmed. The investigative work under the auspices of the A M A Chemical Laboratory will appear in THE JOURNAL next week. It appears that the use in this "elixir" of diethylene glycol—an unstandardized, nonofficial product, not recommended or recognized for internal use—was responsible for the deaths. Diethylene glycol has its proper place in industry, it is safely used in many processes, it is not to be taken in any considerable dosage internally. There is no evidence that its ordinary use in industry or as an ingredient in the manufacture of cigarettes is harmful. The drug sulfanilamide (para-amino benzene sulfonamide) does not seem to be involved so far as the deaths are concerned.

THE JOURNAL is endeavoring to obtain a complete list of the number of cases and of deaths. It asks any physician who has not reported to telegraph to THE JOURNAL (collect), giving the names and location of the patients. This will avoid possible duplication and permit an adequate report of the most unfortunate incident in the pharmaceutical industry within the last decade.

Certainly it should be unnecessary to warn again about the hazard of prescribing unstandardized and uncontrolled remedies. While it seems unbelievable that any manufacturer would circulate and promote the use of preparations for internal use without adequate preliminary tests of toxicity on animals and man, this incident shows that it can be done. The Food and Drugs Administration of the U S Department of Agriculture has rendered conspicuous service in the present circumstance, even though our present laws are so woefully inefficient as to hamper its authority. It has traced practically every shipment and given warning of the potential hazard. The catastrophe that has occurred may well stimulate congress to the development of comprehensive and effective legislation.

INJECTION TREATMENT OF HERNIA

The recent wave of enthusiasm over the injection method of hernia had its impetus in the successes of sclerotherapy in varicose veins and hemorrhoids. Some disappointment with the results of surgical procedure, particularly in cases of direct inguinal hernia, was an additional reason for the revival of a method long relinquished and tainted by quackery.

According to recent reports by Bratrud, Rice, Harris and White, and Fowler the rationale of the treatment depends on the property of mildly irritant solutions to produce a fibrosis when injected into normal tissues, and on the ability of the fibrosis thus produced to obliterate the inguinal canal by causing an intimate adherence of the muscular layers in this region by much the same mechanism as that obtained by suturing. Harris and White¹ injected such irritants into the muscles of the thigh in a group of normal guinea-pigs. They found that these solutions provoked a polymorphonuclear leukocytic response of short duration, followed by a gradually increasing reaction from the mononuclear mesenchymal elements, which later differentiated into spindle cell fibroblasts, resulting in fibrosis. MacMillan and Cunningham, Fowler, Rice and others have obtained similar results. Rice² has obtained microscopic proof of the occurrence of fibrosis in human beings in biopsies from patients who have been operated on for the cure of hernia after having submitted to one or two injections at varying intervals before the operation was performed.

The injection method, according to its modern advocates, is applicable only to hernias that can be completely reduced and kept reduced by means of a truss. Its use is contraindicated in irreducible hernias, in sliding hernias and in the presence of an undescended testis. Injections are further contraindicated in the presence of superficial skin infections or erosions caused by the truss, in syphilis, diabetes, senility or marked emaciation. Hernias with a wide ring are not likely to give a good result. A condition sine qua non is a properly applied truss capable of keeping abdominal contents out of the sac at all times. This is frequently impossible in obese patients and in nervous and restless children. The case best suited for the treatment is the small, reducible, indirect inguinal hernia in a young person. The complicated hernias and the large hernias of the middle aged and the elderly are the least suited for the injection treatment. Anatomic conditions in a direct hernia, in the umbilical and the femoral hernia, make the injection treatment undesirable, in the opinion of many.³

The treatment as outlined by Harris and White consists of (1) from eight to twelve preliminary injections in a period of one month, (2) four reinforcing injections once a week to consume another

1 Harris F I and White A S. Injection Treatment of Hernia: Its Experimental Basis. California & West Med 15: 142 (Nov) 1937.
2 Rice C O. In discussion of Bratrud A F. M. J. 15: 441 (July) 1935.
3 Mason J C. In discussion of Bratrud A F.

month, (3) immediate follow-up examinations once a month for six months (if necessary, occasional reinforcing injections may be made) and (4) final follow-up examinations every two months for one year. The entire treatment requires twenty months for each case. The following are possible complications: an unusually severe local reaction, strangulation, perforation of the bowel, fecal fistula, peritonitis, abscess, atrophy of the testicle, sexual impotence. The needle may enter a vein or artery. The fluid may be placed too deeply or too superficially. If placed too deeply, it may enter the cord or peritoneal cavity. Injection of the cord results in edema of the penis, scrotum and epididymis. Such swellings are not uncommon with this method. A certain amount of pain and transient swelling occur, according to Harris and White, with almost every case. The injection of the fluid into the peritoneal cavity produces an attack characterized by an initial chill and severe abdominal cramps, pain of extraordinary severity in both testes and in the penis, leading to shock. Harris and White state that the fitting and care of trusses require a number of days and careful examination. The treatments themselves are exacting and require skill. The numerous possibilities for dangers and complications make continuous vigilance necessary. "Even in the hands of competent men, this method may be found unsatisfactory for these reasons"⁴. Harris and White report a recurrence of 4.1 per cent in a follow-up study of 121 completed "good surgical risk" cases of inguinal hernia. In forty-one cases of inguinal hernia considered a poor surgical risk, their recurrence rate amounted to 19.5 per cent. MacKinney, in a follow-up study of 300 cases, found 83 per cent cured after six months to three and one-half years. Rice reported 97.6 per cent cured out of 379 patients after not less than six months. Bratrud, at the University of Minnesota Hospital Clinic, had only nine cases out of a total of 707 in which "final closure could not be obtained" but states "I shall be very well pleased if we can keep our recurrences below 10 per cent."

The statement that the treatment has no fatalities is misleading and unwarranted. Bratrud⁵ mentions a case in which 16 minims (1 cc) of phenol-thuja solution had been injected into the peritoneal cavity, causing perforation of the diaphragm and death. Collins⁶ observed two fatal cases of pulmonary embolism, a secondary gangrene of the sigmoid and upper rectum, and two complete bowel obstructions resulting from accidental escape of some of the fluid into the peritoneal cavity. Ziemann and Larkowski⁷ report a case of necrosis of the cord following a single injection of thuja solution.

⁷ Ziemann S. A. and Larkowski T. M. Necrosis of Cord Structures Following the Injection Treatment of Reducible Hernia. *J A M A* 107: 1558 (Nov. 7) 1936.

In striking contrast to the favorable reports of Bratrud, Rice, Harris and White are those of Burdick and Coley⁸ reporting from the Hospital for Ruptured and Crippled, in New York. These authors treated ninety-two hernias in sixty-six patients by the injection method. Of fifty-six cases followed up, a definite relapse was noted in forty-seven, or 81.03 per cent. At present, eleven patients are apparently cured and nine of these are still wearing trusses. In the face of such disappointing results, they have abandoned the treatment.

Rice states that the end results from this method cannot be accurately adjudged at this time because the results do not extend over a period of more than two years. Bratrud expects not less than 10 per cent of recurrences from the more complicated cases. Fowler states "A frank and truthful answer is that as yet we have but little exact and dependable information as to the recurrence rate of the injection treatment."

Although in the hands of some investigators the results seem to have been good, the complications, the difficulty in selecting suitable cases, and the still uncertain percentage of recurrences would seem to make the method unsuitable except under circumstances in which unusually careful technique and suitable care are possible. Careful follow-up studies for a sufficiently long period will undoubtedly furnish data on which to evaluate it.

PERITONEAL PROTECTION

Protection of the peritoneum against infection has been attempted by many investigators since Issayeff¹ in 1894 found that intraperitoneal injections of sterile irritants, such as blood serum, broth and sodium chloride solution, increased peritoneal resistance to bacteria. However, such substances and the usual bacterial vaccines were at best only moderately effective in protecting patients from peritonitis; these materials at the same time produced local and systemic reactions that were always unpleasant and often severe. Issayeff's method nevertheless constituted a valuable lead toward future experimentation. More than thirty years later, the peritoneal "struggle mechanism" was clarified by Steinberg and his associates². They demonstrated that satisfactory peritoneal protection is determined by three factors: 1. A sufficiently large number of phagocytic cells (polymorphonuclears) must be mobilized to phagocytose invading bacteria and to prevent bacterial multiplication and elaboration of soluble toxic substances. 2. Such a mobilization requires retention of the

leukocyte evoking antigen within the peritoneal cavity, most antigens, including ordinary suspensions of bacteria, leave the peritoneum too rapidly to be effective.³ The antigen must be of such character as to bring to the peritoneum the necessary quantity of phagocytic cells with sufficient rapidity.

In an extensive series of experiments, Steinberg and Goldblatt⁴ demonstrated conclusively that a solution of gum tragacanth holding in suspension a prepared strain of *Escherichia coli* treated by long exposure to a weak solution of formaldehyde fulfilled these three requirements. Subsequent clinical experiences of Potter and Coller,⁵ Coller and Ransom⁶ and other surgeons have confirmed these studies. The protecting material developed by Steinberg prevented peritonitis even when gross fecal soiling of the peritoneum occurred, at the same time reactions were reduced to a minimum. Since mobilization of the phagocytes is achieved in three hours (and bacterial multiplication inducing peritonitis requires from eighteen to twenty-four hours) the protective material may be introduced at the time of operation even in the presence of gross contamination.

The investigations of Steinberg and his collaborators would seem to be of inestimable value in eliminating a major hazard of abdominal surgery. Nevertheless, the search for such a technic has been so long and the disappointments have been so many that many more studies should be made promptly to establish the real and practical worth of the method.

Current Comment

EXPERIMENTAL ANEMIA

Recently Rhodes and Miller² reported a study of the effects of a combination of aminopyrine and nutritional deficiency on the blood of dogs. They found that dogs fed on normal diets could be given 0.5 Gm of aminopyrine by stomach tube daily without demonstrable change in the blood picture. They further found that dogs on the Goldberg pellagra-producing (black tongue) diet also usually failed to develop any appreciable anemia. A combination, however, of this diet and 0.5 Gm of aminopyrine daily led to a pronounced and at times fatal anemia in from eight to thirty-five days. Daily administration of 10 Gm of yeast autolysate would prevent or cure this anemia. These observations

led Rhodes² to study the action on the blood of dogs of other toxic products of endogenous origin. When indole was used for this purpose, Rhodes found that normally fed dogs could be given a capsule containing 1 Gm of crystalline indole daily without appreciable effect on the blood picture. If dogs previously fed on the Goldberg diet for some five to twelve weeks were given 1 Gm of indole daily, they invariably showed a precipitous fall in hemoglobin content and in the numbers of red blood cells. The red cells usually fell to less than a million per cubic millimeter by the fourth or fifth week. Similar anemias occurred in dogs fed exclusively on milk. Even when the dogs were maintained on the blacktongue diet, administration of liver extract prevented or cured the indole anemia. Similar recoveries were noted when the animals were returned to a normal diet. These observations may reopen the whole question of gastro-intestinal auto-intoxication.

MEASURING IMMUNITY IN WHOOPIING COUGH

The optimistic reports about thirty years ago on the use of the "opsonic index" as a method of clinical diagnosis were soon followed by almost complete abandonment. Interest in cytophagic immunity has been recently revived, however, by attempts to simplify the technic. One of these variations—that described by Huddleson—has been applied by Kendrick and her co-workers¹ in a study of immunity in pertussis and of the efficiency of antipertussis vaccines. Cells containing no micro-organisms are given a rating of 0, those with from one to five micro-organisms a rating of 1. Cells containing from six to twenty bacteria are recorded as rating 3, from twenty-one to forty micro-organisms an average of 8, and so on. From these recorded ratings the average rating per leukocyte is readily calculated. Applying this method to a child given a series of four nonviable *Bacillus pertussis* injections, the Michigan serologists found that the opsonocytaphagic titer rose from 0 to a maximum of 3, which was reached one week after the fourth dose of vaccine. The titer remained at this high level for about eight weeks and then gradually fell to 2 by the end of one year. The average rating of sixty-eight children given a similar series of four injections of vaccine rose from an initial rating of 0.3 to a maximum of 2.7 a week after the fourth immunizing dose, fell to 1.9 by the end of one year, and remained at this level till the end of the second year. In a second series of forty-nine children given smaller doses of pertussis vaccine the initial rating (0.1) was increased to 2.3 after the fourth injection, falling to 1.6 by the end of one year and to 0.7 by the end of the second year. The variations in the opsonocytaphagic rating in 119 nonvaccinated subjects during an attack of pertussis is of particular interest. During the first two weeks after the onset of symptoms the average rating was 0.8, which increased to a maximum of 2.3 by the eighth week of the disease. The titer then gradually fell to a fairly stationary level of

09, which was maintained till the end of the second year. In a parallel study of 154 nonvaccinated subjects with no history of pertussis, a suggestive parallelism was noted between age group and opsonocytaphagic titer. With age groups under 9 years the average rating varied from 0.2 to 0.3. With twenty-two persons over 20 years of age the average cytophagic titer was 1.2. In skilled hands the new technic may prove to be of considerable diagnostic aid.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Changes in Health Officers—Dr. William H. Goff, formerly of Glasgow, Ky., has been placed in charge of the Coosa County Health Department, with headquarters in Rockford. —Dr. Benjamin S. Black, Grove Hill, has been appointed health officer of the newly created Clarke County Health Unit. —Dr. Douglas H. Fryer, Toronto, Ont., was recently chosen health officer of Greene County.

Society News—The Northwestern Division of the Medical Association of the State of Alabama was addressed at Russellville, September 16, by Drs. Hubert K. Turley, Memphis, Tenn., on "Pyelitis of Pregnancy", Dan C. Donald, Birmingham, "Diagnosis and Management of Colon Lesions", Ralph M. Clements, Tuscaloosa, "Psychological Aspects of Ear, Nose and Throat Disease", Albert C. Jackson, Jasper, "Management of Fractures of the Shaft and Proximal End of the Humerus," and Seale Harris Jr., Birmingham, "Treatment of Central Nervous System Syphilis."

CALIFORNIA

Personal—Dr. Emmett E. Sappington has been temporarily appointed assistant director of public health of San Francisco pending examination by the civil service commission.

Society News—A joint meeting of the Los Angeles Society of Neurology and Psychiatry and the internal medicine section of the Los Angeles County Medical Association will be addressed November 3, among others, by Dr. Charles F. McCuskey, on "Alcohol Injection for the Relief of Anginal Pain"—Dr. Archie M. Roberts, among others, discussed "Repeated Coronary Thrombosis with Peripheral Embolism and Embolectomy" before the Los Angeles Heart Association, October 19.—A symposium on legal medicine was presented before the San Francisco County Medical Society, October 12, by Dr. Joseph Catton, San Francisco, Dr. Frederick Proescher, San Jose, Dr. Adelbert M. Moody, Harley F. Peart and Dr. Jesse L. Carr, San Francisco.—Lieut. Albert R. Behnke Jr., M. C., U. S. Navy, addressed the Hollywood Academy of Medicine, October 21, on "Submarine Medicine."

FLORIDA

Annual Meeting of East Coast Society—The tenth annual meeting of the Florida East Coast Medical Society will be held at Hollywood, November 12-13. The following program has been announced:

Dr. Milton Paul Travers, Miami: Fractures of the Spine.
Dr. Edward Sterling Nichol, Miami: Clinical Significance of Asthma in Heart Disease.
Drs. Eugene Clay Shaw and Jack A. McKenzie, Miami: Vaginal Approach to Stone in the Lower Ureter.
Dr. Charles B. Mabry, Jacksonville: Some Observations on Hip Fractures.
Drs. Kenneth Phillips and Ammon Buist Litterer, Miami: Diagnostic Value of the Neutralizing Function of the Stomach.
Dr. Theodore F. Hahn Jr., DeLand: Gonococcal Peritonitis of the Right Upper Quadrant.
Dr. Elijah T. Sellers, Jacksonville: Some Observations of Treatment with Sulfanilamide.
Dr. Louie M. Lambaugh, Jacksonville: Protamine Insulin in the Treatment of Diabetes Mellitus.
Dr. A. Daniel Amerise, Coral Gables: Treatment of Poisonous Snake Bites.
Dr. Duncan T. McEwan, Orlando: Stricture of the Rectum in Lymphopathia Venereum.

GEORGIA

Society News—The Fulton County Medical Society was addressed October 21 by Dr. Arthur Park McGinty, Atlanta, among others, on "The Comparative Effects of Pregnancy and Phrenic Nerve Interruption on the Diaphragm with Their Relation to Pulmonary Tuberculosis"—Justin M. Andrews, Sc.D., Baltimore, discussed "Malaria Control in the South" before the Southwest Georgia Public Health Association in Valdosta, September 2.

Changes in the Faculty at Georgia—The University of Georgia School of Medicine announces the appointment, October 1, of the following clinical teachers with the title of associate professor and in charge of the departments indicated:

Dr. Richard Frank Slaughter Jr., formerly of Norfolk, Va., neurosurgery.

Dr. Hervey M. Cleckley, Augusta, psychiatry.

Dr. Lucius N. Todd, Waverly Hills, Ky., tuberculosis.

Dr. Perry P. Volpitta, New York, anesthesia.

IDAHO

State Medical Election—Dr. Frank C. Gibson, Pocatello, was chosen president-elect of the Idaho State Medical Association at its recent annual meeting in Boise, and Dr. Arthur C. Jones, Boise, was installed as president. Dr. Harold W. Stone, Boise, was reelected secretary. It was decided to hold the next annual meeting of the association at Sun Valley.

Society News—The Pocatello Medical Society was addressed in Pocatello, October 7, by Dr. Abram M. Newton, Pocatello, on "Fractures of the Femur." A proposal to combine the society with the Idaho Falls Medical Society for the purpose of holding two major meetings each year, the programs to be given by notable speakers, was discussed at the recent meeting.

ILLINOIS

Acting State Health Officer—Dr. Frank J. Jirka, since 1933 health officer of Illinois, has resigned to reenter private practice in Chicago. Dr. Albert C. Baxter, assistant director of the department since Feb. 1, 1930, has been appointed acting director. Dr. Jirka's resignation was to be effective September 1, according to a recent announcement, but he continued in office during the outbreak of infantile paralysis. Dr. Baxter graduated from the University of Michigan Medical School, Ann Arbor, in 1907.

Chicago

New Tumor Institute—Coutard and Cheate Come to Chicago—Organization of the Chicago Tumor Institute, chartered in Illinois, not for profit, to conduct research on the causes, diagnosis and treatment of cancer and to instruct and assist physicians, surgeons, clinics and hospitals in the diagnosis and treatment of cancer, has been announced. The trustees include Dr. Ludwig Hektoen, Arthur H. Compton, Ph.D., Dr. Max Cutler, Mr. Modie J. Spiegel Sr., Mrs. Margaret Pirie Beacom, Mrs. Francis Neilson, Mrs. Arthur Mcelcer, Mr. Alfred Busiel and Mr. Roy C. Osgood, all of Chicago.

Dr. Hektoen, director of the John McCormick Institute for Infectious Diseases, and recently appointed member of the council of the National Cancer Institute, has been elected president of the board of the Chicago Tumor Institute. Dr. Compton, professor of physics at the University of Chicago, has been elected vice president, Roy C. Osgood vice president of the First National Bank of Chicago, treasurer and Mr. Louis P. Haller, secretary. Mr. Maurice Berkson has acted as counsel in the organization of the institute. The institute will be directed by a scientific committee consisting of Dr. Cutler, Dr. Henri Coutard of the Curie Institute, Paris, France, Sir George Lenthal Cheate, London, England, Dr. Compton, and Dr. Hektoen.

Plans have been completed for the remodeling of the building at the southeast corner of Dearborn and Elm streets, which will house the activities of the institute. The building is to be ready for occupancy and the institute will begin to function about March 1, 1938. The institute will be equipped with research laboratories, and modern x-ray and radium equipment. Dr. Coutard, now in Paris, will return to Chicago about November 10. At the request of the California Institute of Technology, the Chicago Tumor Institute has granted Dr. Coutard leave of absence for three months in order to carry on research with the 1,000,000 volt x-ray machine in the laboratory of Prof. Robert A. Millikan at Pasadena but he will return to Chicago at the time of the opening of the new institute about March 1 next. Sir Lenthal is now in Chicago and will spend most of his time in laboratory research and in graduate instruction. Dr. Cutler resigned as director of the tumor clinic at Michael

Reese Hospital, September 15, to direct the institute. One of the important functions of the institute is to train physicians and surgeons desiring to specialize in the diagnosis and treatment of cancer. Two members of the staff of the Peiping Union Medical College, supported by the China Medical Board of the Rockefeller Foundation, have already arrived in this country to take their training at the Chicago Tumor Institute. Although the scope of the activities of the institute will be national, the contributions to its funds have been made entirely by citizens of Chicago.

New X-Ray Department at St. Luke's Hospital—The formal opening of the new x-ray department at St. Luke's Hospital took place October 23. In the evening, with Dr. Edward L. Jenkinson, director, department of radiology at the hospital, as chairman, the following program was presented:

Charles H. Schweppe, president board of trustees, address of welcome.
Dr. Selim W. McArthur, president medical staff, "The Development of the X-Ray Department and Its Future."

Dr. Arthur R. Elliot, senior member of the medical staff, "The Medical Uses of the X-Rays."

Dr. Byrl R. Kirklin, Rochester, Minn., "The X-Rays in Medicine and Some Indications for Their Employment in the Diagnosis of Gastro-Intestinal Diseases."

Dr. Arthur U. Desjardins, Rochester, Minn., "Radiotherapy for Inflammatory Conditions."

The new department occupies the entire second floor of the main building of the hospital and three rooms on the nineteenth floor with a reserve film storage room on the roof representing altogether an investment of about \$140,000. Sixteen rooms are assigned for the making of roentgenograms or the treatment of patients, twelve others are used for allied purposes, such as a waiting room for patients or their visitors, a consultation room, linen closet and offices. A feature of the department is a bronchoscopy room, equipped with a biplane fluoroscope, said to be the only one of its kind west of Philadelphia. It has a built-in operating table. Two rooms are devoted to supervoltage therapy for deep-seated cancer. Ordinarily voltages of from 400,000 to 500,000 will be used, but 850,000 volts constant potential can be developed when necessary. One therapy room is equipped with a shock-proof couch so that the patient may be treated from above or below with voltages as high as 200,000. The x-ray photographic rooms have machines for all kinds of specialized work. There is a machine for serial films of the stomach taking twelve exposures on one film to show the movements of the stomach or intestine. There is also a museum where films and reductions are stored and indexed for teaching purposes.

IOWA

Society News—Dr. William E. Chamberlain, Philadelphia, will discuss "Low Back Pains" before the Linn County Medical Society, Cedar Rapids, November 4, among other speakers. The society was addressed, October 8, by Drs. John M. Wheeler, New York, on "Effective Plastic Operations for Deformities About the Eyes"; Meyer Wiener, St. Louis, "Things Which the General Practitioner Should Know About Ophthalmology," and Joseph Norman Bickert, Cedar Rapids, "Use of Electrocoagulation in the Treatment of Cervicitis and Endocervicitis."—At a meeting of the Johnson County Medical Society in Iowa City, October 6, Dr. Axel Anies Jr., Iowa City, discussed "Suction Treatment in Empyema."—The Lee County Medical Society was addressed in Fort Madison, September 23, by Drs. Horace M. Korns, on "Diagnosis and Treatment of Peripheral Vascular Disease"; Ruben Nomland, "Diagnosis and Treatment of Common Skin Diseases," and Julian D. Boyd, "After-Care in Children's Diseases," all are of Iowa City.—The medical and dental societies of Marion County held a joint meeting at Pleasantville, September 23, speakers included Dr. Donald B. Williams, Knoxville, on poliomyelitis.—Dr. William C. Buchbinder, Chicago, discussed "The Treatment of Peritonitis" before the Austin Flint-Tri-District Medical Society in Charles City, September 9.—Dr. Samuel M. Feinberg, Chicago, addressed the Woodbury County Medical Society at Sioux City, October 13, on "Problems in the Management of the Asthmatic."

MAINE

Society News—Dr. Thomas A. Foster, Portland, discussed "The Care and Treatment of the New-Born" before the Franklin County Medical Society, September 13.—At a meeting of the Kennebec County Medical Association, September 8, Dr. Albert Warren Stearns, Boston, discussed "Revolutionary Medicine—A Note on the Beginning of Organized Medicine in New England."—A recent meeting of the Somerset County Medical Society in Lakewood was addressed, among others, by Dr. Charles W. Steele, Auburn, on "Treatment of Cardiac

Incompetence and Hypertension."—The Washington County Medical Society was addressed at St. Stephen, N. B., recently by Drs. Charles H. Best, Toronto, on "Thrombosis Formations," and Frank Scott, Toronto, "Malignancy of the Esophagus."

MARYLAND

The Dohme Lectures—Einar Lundsgaard, professor of physiology, Institute of Medical Physiology, University of Copenhagen, Denmark, will deliver the Dohme Lectures at Johns Hopkins University School of Medicine, Baltimore, November 10-12. The titles of the lectures are:

The Chemistry of the Anaerobic Muscular Contraction
The Metabolism of the Aerobic Working Muscles
The Metabolism of the Isolated Liver

MASSACHUSETTS

Hospital News—Dr. Andrew C. Ivy, Nathan Smith Professor of physiology and professor of pharmacology, Northwestern University Medical School, Chicago, gave a lecture at the Massachusetts General Hospital, October 8, on "Oral Enzyme Therapy and Bile Formation."

The Dunham Lectures—Dr. Corneille Heymans, professor of pharmacology, University of Ghent, Belgium, will deliver three lectures at Harvard University Medical School, Boston, under the Edward K. Dunham Lectureship for the Promotion of the Medical Sciences. His subjects will be:

November 8, "The Mechanisms of Vasomotor Tone and Blood Pressure Regulation."
November 10, "The Mechanisms of Vasomotor Tone and Blood Pressure Regulation (continued)."
November 12, "The Role of the Aortic and Carotid Sinus Pressoreceptors and Chemoreceptors in the Reflex Control of Respiration."

MINNESOTA

Society News—At a meeting of the East Central Minnesota Medical Society in Braham, September 22, Dr. Thomas A. Peppard, Minneapolis, discussed "Use of Digitalis and Quinidine in Heart Diseases" and Dr. Otto Yoerg, Minneapolis, "Improved Treatment of Fractures of Os Calcis."—Among others, Dr. James F. Weir, Rochester, addressed the Wabasha County Medical Society, October 7, on "The Medical Treatment of Diseases of the Gallbladder."—Dr. Gordon R. Kamman discussed "Bromides, Their Use and Abuse" before the Minnesota Academy of Medicine in St. Paul, October 13, and Drs. Herbert Z. Giffin and Charles H. Watkins, Rochester, presented a paper entitled "The Effect of the Administration of Yellow Bone Marrow in Leukopenic States."—Dr. John C. McKinley, Minneapolis, delivered the presidential address before the Minnesota Pathological Society at its annual meeting, October 19, on "The Pathologic Physiology of the Cerebellum."

Changes in the Faculty at Minnesota—New appointments to the University of Minnesota Medical School, Minneapolis, include the following:

Dr. Wesley W. Spink, formerly of Harvard University Medical School, Boston, assistant professor of medicine.

Dr. Burtrum C. Schiele, formerly of Cornell University Medical College, New York, assistant professor in the division of nervous and mental diseases.

Leo T. Samuels, Ph.D., formerly of the University of Southern California School of Medicine, Los Angeles, assistant professor of physiologic chemistry.

Ancel B. Keys, Ph.D., has been transferred from the department of physiologic chemistry in the Mayo Foundation of the University of Minnesota Graduate School to an associate professorship in the department of physiology of the medical school. According to Dr. Harold S. Diehl, dean of medical sciences, Dr. Keys will develop a teaching and research program in physiology and school health for students majoring in physical education, which will provide an opportunity for graduate work in these fields and for research in the physiology of normal activity.

MISSISSIPPI

Gulf Coast Clinical Society—The annual meeting of the Gulf Coast Clinical Society will be held at the Buena Vista Hotel Biloxi, November 3-4. The following program will be presented:

Dr. Joseph E. Green, Laurel, president-elect, state medical association, "The Economic and Social Side of the Practice of Medicine."

Dr. Edward S. Sledge, Mobile, president, Alabama Electrotherapy Association, "The Clinical Value and Limitations of Electrotherapy."

Dr. Edward Jelks, Jacksonville, president, Florida Medical Association, "The Diagnosis of Gastro-Intestinal Cancer."

Dr. Raymond A. Vonderlehr, assistant surgeon general, U.S. Public Health Service, Washington, D.C., "The Public Health Control of Syphilis."

Dr. Curtice Rosser, Dallas, Texas, "Venereal Diseases of the Anus."

Col Charles F Craig New Orleans Treatment of Malaria
 Dr Horton R Casparis Nashville Tenn The Mental Health Problem in Children
 Dr William C Chaney Memphis How Is the General Practitioner to Diagnose Food Idiosyncrasies?
 Dr Morris Edward Davis Chicago Use and Abuse of Cesarean Section
 Dr Lucius E Burch Nashville Tenn Sterilization of Obstetrical Patients in Vanderbilt University Hospital from 1925 to 1937
 Dr Charles H Heacock Memphis Radiation Treatment of Cancer of the Breast
 Dr Ray M Balyeat Oklahoma City Therapeutic Value of Intratracheal Use of Iodized Oil Combined with Eliminative Measures and Specific Desensitization in the Treatment of Intractable Asthma Chronic Bronchitis and Bronchiectasis
 Dr Edward W Alton Ochsner, New Orleans Peripheral Vascular Disease
 Dr Karl A Meyer Chicago Abdominal Injuries
 Dr J Grafton Love Rochester, Minn Intractable Low Back and Sciatic Pain Due to Protrusion of the Lumbar Intervertebral Disks Diagnosis and Surgical Treatment

Dr Morris Fishbein, Editor of THE JOURNAL Chicago, will address the banquet session in the evening on Social Aspects of Medical Care"

MISSOURI

Large Outbreak of Epidemic Encephalitis—A total of 412 cases of encephalitis with ninety eight deaths were reported to the health division of the St Louis Department of Public Welfare between June 30 and October 18. Of these cases 324 were in residents of St Louis and eighty-eight were nonresident cases, mostly in St Louis County, brought into the city for hospitalization. Of the total number of deaths eighty-six occurred in resident cases and twelve in nonresident. The case fatality rate for all cases was 23.7 per cent, including October 18. Of the total number of deaths 87.7 per cent occurred in persons over 50 years of age, most of the deaths occurred in the 50-59 and 60-69 age groups. The first case of the recent outbreak was reported to the health division on June 30. The outbreak did not really get under way until mid-August when thirteen cases were reported for the week ended August 21. From then on the incidence by weeks was as follows:

Week Ended	Number of Cases
August 28	36
September 4	52
September 11	76
September 18	76
September 25	65
October 2	54
October 9	26
October 16	8

The peak was reached September 7, when twenty-five cases were reported. After this date the incidence slowly decreased to an average of ten cases daily until October 9, when the incidence dropped sharply to an average of one case a day. According to Dr J Earl Smith, epidemiologist, occasional cases continue to be reported. The recent outbreak was similar in all respects to the 1933 outbreak save for a slightly higher incidence among the younger age group and the smaller number of cases reported. Research in the medical schools identified the causative virus of the present outbreak as being identical with the virus that caused the epidemic in 1933. According to Dr Smith, epidemic encephalitis is now apparently endemic in the St Louis area and future outbreaks are anticipated. Thus far no new epidemiologic information can be added to that of the epidemic in 1933. When the present outbreak definitely subsides, an official report will be made.

NEVADA

State Medical Election—Dr Walter H Frolich, East Ely, was named president-elect of the Nevada State Medical Association at its annual meeting in Ely September 24-25 and Dr Harry W Sawyer, Fallon, was inducted into the presidency. Dr Horace J Brown, Reno, was unanimously reelected secretary. The next annual meeting will be in Reno. The association adopted a resolution expressing 'opposition to and unwillingness to cooperate in any plan that involves federal supervision and control of medical practice in the United States'.

NEW YORK

Personal—Dr Richard Slee, White Plains, first deputy health commissioner of Westchester County since 1930 retired October 1. Dr Slee was for many years an officer of the U S Army Medical Corps and was a district health officer of the state health department before his appointment in Westchester County.

Society News—Drs Stanley P Reimann Philadelphia and Louis C Krass, Buffalo addressed the Medical Society of the County of Nassau, October 19 in Garden City L I, on cancer.—Dr Ernest L Stebbins Rochester was the speaker at the quarterly meeting of the Ontario County Medical Society

Canandaigua, October 12, on "Source Diagnosis, Clinical Course and Treatment of Some of the More Common Streptococcus Infections"

New York City

Dr McEwen Appointed Dean at New York University—Dr Currier McEwen, secretary and assistant dean of New York University College of Medicine since 1932, has been appointed dean to succeed the late Dr John Wickoff. Dr McEwen was graduated from the college in 1926 and after a two year internship at Bellevue Hospital spent four years in research at Rockefeller Institute for Medical Research and at the Pathological Institute of the University of Leipzig. He is 35 years old. He is associate visiting physician at Bellevue Hospital, chief of the arthritis subdivision of the university's medical clinic, visiting physician of the research division of chronic diseases of the city department of hospitals, and assistant professor of medicine at the college.

Program of the Graduate Fortnight—The tenth annual Graduate Fortnight of the New York Academy of Medicine will be presented November 1-12. Clinics will be held during the days at various hospitals and evening meetings at the academy building, 2 East One Hundred and Third Street. Speakers at the evening sessions will be:

Dr Alfred N Richards Philadelphia the Wesley M Carpenter lecture
 Physiology of the Kidney
 Donald D Van Slyke Ph.D New York Tests for Kidney Function
 Dr Dana W Atchley New York Edema and Its Treatment
 Dr Arthur M Fishberg New York Uremia and Pathology of Kidney Function
 Dr Milton C Wintermiz New Haven Conn Pathology of Vascular Disease
 Dr George Baehr New York Pathology of Nephritis
 Dr Robert F Loeb New York Clinical Aspects of Nephritis
 Dr Irvine H Page Indianapolis Nature of Hypertension
 Dr Herman O Mosenthal New York Clinical Aspects of Hypertension Including Malignant Hypertension
 Dr George J Heuer New York Evaluation of the Surgical Treatment of Hypertension
 Dr Albert A Epstein New York The Nephroses
 Dr William W Herrick New York Vascular and Renal Complications of Pregnancy
 Dr Karl A Menninger Topeka Kan The Emotional Factors in Hypertension
 Dr William F Braasch Rochester Minn Pathogenesis and Treatment of Renal Infections
 Dr Hugh Cabot Rochester Minn Renal and Perirenal Infections
 Dr John R Caulk St Louis Renal Tuberculosis
 Dr Linwood D Keyser Roanoke Va Calculus Disease the Formation of Stones
 Dr Henry G Bugbee New York Clinical Aspects of Calculus Disease
 Dr William C Quinby Boston Mass Hydronephrosis and Pyonephrosis
 Dr John D Lyttle New York Bright's Disease in Children
 Dr Meredith F Campbell New York Common Urologic Diseases in Children
 Dr Benjamin S Barringer New York Radiotherapy of Tumors of the Urinary Tract
 Dr Archie L Dean Jr New York Tumors of the Kidney and Ureter
 Dr Edwin Beer New York Tumors of the Urinary Bladder
 Dr William E Lower Cleveland Pathologic Physiology of Bladder Neck Obstruction
 Dr Joseph T McCarthy New York Transurethral Resection of Bladder Neck Obstruction
 Dr Hugh H Young Baltimore Surgical Treatment of Obstructions at the Neck of the Bladder

NORTH CAROLINA

Symposium on Gynecology, Obstetrics and Pediatrics—Duke University School of Medicine and Duke Hospital, Durham, announce a graduate symposium on gynecology, obstetrics and pediatrics to be given November 11-13. The program includes the following speakers, among others: Drs Horton R Casparis Nashville, Tenn, Willard R Cook, Galveston, Texas, Julius H Hess Chicago, Howard F Kane Washington D C, Foster S Kellogg, Boston, George W Kosmak New York, Esther L Richards, Baltimore, and Charles H Smith New York.

OHIO

Annual Graduate Day in Toledo—The Medical Institute of the University of Toledo will present the fourth annual Postgraduate Day Friday, November 19, with Drs Frank H Lahay and Lewis M Hursthal, Boston, as the speakers. Dr Lahay will discuss the surgical aspects of hyperthyroidism and Dr Hursthal the medical aspects.

Courses in Venereal Disease Control—Graduate courses in venereal disease control have been instituted by Western Reserve University School of Medicine Cleveland under authority of the state director of health and the U S Public Health Service. Health officers and physicians in the following states are eligible: Ohio Michigan Indiana Illinois, Wisconsin Minnesota Iowa Missouri Kansas Nebraska, North and South Dakota. Students may enter the course at any

time when a vacancy exists, usually for a duration of three or four months. Visitors may be admitted for shorter periods if they can be accommodated. The training will be informal and adapted to the needs of those taking the course, according to the announcement. Physicians who wish to take the courses should apply through their state health departments to the state director of health of Ohio. Application blanks may be obtained from Dr. Calvin C. Applewhite, regional consultant for the U. S. Public Health Service, Room 314, U. S. Court House, Chicago.

PENNSYLVANIA

State Medical Election—Dr. David W. Thomas, Lock Haven, was named president-elect of the Medical Society of the State of Pennsylvania at the annual meeting in Philadelphia, October 5-8, and Dr. Frederick J. Bishop, Scranton, was installed as president. Dr. Walter F. Donaldson, Pittsburgh, was reelected secretary. Next year's meeting will be in Scranton.

Philadelphia

Mr. H. K. Mulford Dies—Mr. Henry Kendall Mulford, director of the research and biological laboratories of the National Drug Company since 1926 and president of the Mulford Colloid Laboratory, died October 15, aged 71. Mr. Mulford graduated from the Philadelphia College of Pharmacy in 1887 and founded the H. K. Mulford Company in 1890. He retired from the presidency of that company in 1918.

Symposium on Sulfanilamide—A program of papers on "Chemotherapy in Streptococcal and Gonorrheal Infections" was presented before the Philadelphia County Medical Society October 13 by Drs. Thomas Fitz-Hugh Jr., who discussed untoward reactions of sulfanilamide therapy; Harry P. Schenck, sulfanilamide in otolaryngology, and Dickinson Sergeant Pepper, sulfanilamide management of outpatient gonorrhea. Dr. Percy S. Pelouze led the discussion of the papers.

Society News—Speakers who addressed the Philadelphia Neurological Society October 22 were Drs. Harry M. Zimmerman, New Haven, Conn., on "Newer Aspects of the Nervous Disorders in Avitaminosis", Katherine O. Shea, Elsom Haverford, Pa., "B. Avitaminosis in Clinical Medicine," and Fritz J. Lewy, "Neurologic Aspects of B. Avitaminosis." At a meeting of the Northern Medical Association October 18 the speakers were Drs. Pascal F. Lucchesi on "Prevention and Treatment of Exanthemata", John S. Lockwood, "Indications and Contraindications for Sulfanilamide," and Hobart A. Reimann, "The Pneumonias." The committee on maternal welfare of the Philadelphia County Medical Society presented the program at a meeting of the society October 27, with the following physicians as speakers: Drs. Thaddeus L. Montgomery, Newlin Fell Paxon, Alberta Peltz, Robert A. Kimbrough Jr., James Marsh Alesbury.

TEXAS

Public Health Meeting in Dallas—The fifteenth annual meeting of the Texas Public Health Association will be held at the Hotel Adolphus, Dallas, November 1-3. Among the speakers listed on the preliminary program are:

Henry F. Vaughan, Dr. P. H., Detroit: Finding the Early Case of Tuberculosis.
Dr. Reginald M. Atwater, New York: Today's Trends in Public Health.
Dr. Matthew R. Kinde, Marshall, Mich.: subject not announced.
Gov. James V. Allred, Austin: Full Steam Ahead for Health Work in Texas.
Dr. Calvin R. Hannah, Dallas: How We Can Save Texas Mothers and Babies.

Graduate Assembly in Houston—The eighth, ninth and tenth councilor districts of the State Medical Association of Texas will hold their sixth annual Post-Graduate Medical Assembly of South Texas November 2-4 at Houston. The following lecturers have been announced: Drs. Nathaniel G. Alcock, Dean M. Lierle and William Malamud, Iowa City; Carl E. Badgley, Ann Arbor, Mich.; Claude S. Beck and Russell L. Haden, Cleveland; Nicholson J. Eastman and Charles F. Geschickter, Baltimore; Tinsley R. Harrison, Nashville, Tenn.; Emile F. Holman, San Francisco; Albert Graeme Mitchell, Cincinnati; Quitman U. Newell and Lawrence T. Post, St. Louis; George E. Shambaugh Jr., Chicago; William D. Stroud, Philadelphia; and Georgiana M. Dvorak Theobald, Oak Park, Ill.

VERMONT

State Medical Election—Dr. Frank C. Phelps, Vergennes, was elected president of the Vermont State Medical Society at the annual meeting October 13. Dr. Leon E. Sample, St. Albans, was elected vice president and Dr. Benjamin F. Cook, Rutland, secretary. The 1938 meeting will be in Burlington.

GENERAL

Society News—Dr. George M. Coates, Philadelphia, was chosen president-elect of the American Academy of Ophthalmology and Oto-Laryngology at the annual meeting in Chicago October 11-15 and Dr. Harry S. Gradle, Chicago, was installed as president. The following were elected vice presidents: Drs. Ernest M. Seydell, Wichita, Kan.; Webb W. Weeks, New York; and John H. Foster, Houston, Texas. The 1938 convention will be held in Washington, D. C.—The American Proctologic Society will hold its next annual meeting at the St. Francis Hotel, San Francisco, June 11-14, 1938. Dr. Granville S. Hanes, Louisville, Ky., will deliver the first annual Joseph M. Matthews address. Guests sponsored by members of the society will be admitted to the sessions.—Dr. Alphonse R. Dochez, New York, was elected president of the American Clinical and Climatological Association at its annual meeting, October 12, and Dr. Francis M. Rackemann, Boston, was reelected secretary. The next annual session will be held in Atlantic City, May 24, 1938.

Pan American Cruise Congress—The *Queen of Bernice* will sail from New York January 15 for the seventh cruise congress of the Pan American Medical Association and will return January 31. There will be five days of scientific meetings in Havana and stops will also be made at Port au Prince, Haiti; Trujillo City, San Domingo; and San Juan, Puerto Rico. All the countries to be visited have extended official invitations to the association to be their guests and plans for entertainment are being made, according to an announcement. Chairmen of the sections of the association, which will hold meetings on shipboard as well as in Havana and in the other ports, have been announced as follows:

Tropical medicine: Col. Charles F. Craig, New Orleans.
Thoracic section: Dr. Jay Arthur Myers, Minneapolis.
General medicine: Dr. Howard R. Hartman, Rochester, Minn.
Public health: Dr. Claude W. Munger, New York.
Gynecology and obstetrics: Dr. Henry Dawson Furniss, New York.
Orthopedic surgery: Dr. John Royal Moore, Philadelphia.
General surgery: Dr. William D. Haggard, Nashville, Tenn.
Otorhinolaryngology: Dr. William E. Sauer, St. Louis.
Cancer: Dr. James Ewing, New York.
Radiology: Dr. Edwin C. Ernst, St. Louis.
Urology: Dr. Elmer Hess, Erie, Pa.
Neurology, neurosurgery and psychiatry: Dr. Foster Kennedy, New York.

Ophthalmology: Dr. Webb W. Weeks, New York.
Dermatology and syphilology: Dr. Elmer B. Tauber, Cincinnati.
Pediatrics: Dr. Orville E. Barbour, Peoria, Ill.
Physical medicine: Dr. William Bierman, New York.
Industrial medicine and surgery: Dr. John B. Lauricella, New York.
Dentistry: Alfred Walker, DDS, New York.

Dr. Alberto Inclan, Havana, is president of the association and Dr. Joseph J. Eller, New York, is director general.

Government Services

Dr. Whitehead Retires from Bureau of Air Commerce

Dr. Roy E. Whitehead, medical director of the medical section of the bureau of air commerce, Washington, D. C., has resigned, newspapers report. He had held the position since November 1933. Dr. Eldridge S. Adams, Washington, D. C., whom Dr. Whitehead originally succeeded, has been appointed acting head of the section, it was stated.

Openings for Physicians at St. Elizabeths Hospital

Examinations for two positions as junior medical officer at St. Elizabeths Hospital, one a rotating internship and the other a psychiatric residency, are announced by the U. S. Civil Service Commission. Salaries will be \$2,000 a year. For the rotating internship applicants must be fourth year students in grade A medical schools, for the residency they must have completed four years of study in a grade A school not prior to Jan. 1, 1935, and must have the degree of M.B. or M.D. and must have completed an internship of one year except that applications will be accepted from persons now serving an accredited rotating internship. Full information about these examinations may be obtained from the secretary of the U. S. Civil Service Board of Examiners at the postoffice or customhouse in any city that has a postoffice of the first or second class or from the commission at Washington, D. C. Applications must be received not later than November 29 from states east of Colorado and December 2 from Colorado and westward.

Differential Diagnosis of Mediastinal Tumors

At the Royal Society of Medicine, Dr N L Rusby discussed the differential diagnosis of mediastinal tumors. He pointed out that the history of the patient was important in distinguishing a tumor of the mediastinum. A history of specific disease years previously may engender great caution in diagnosing tumor rather than aneurysm of the aorta. The history of intimate contact with a phthisical parent may in a seedy looking child suggest tuberculous mediastinal lymphadenitis as the cause of a dry, hacking cough, rather than Hodgkin's disease or lymphosarcoma of the thymus. Benign tumors of the mediastinum may cause no symptoms whatever. At the end of the last century, before the advent of x-rays, they were commonly found during the routine necropsy, while today they are sometimes revealed by the roentgenogram taken to exclude phthisis in a tuberculous contact. When symptoms do become manifest they are the result of either pressure of the tumor within the thorax or supervention of some complication, such as hemorrhagic infection or a bronchial fistula. The dermoid cyst is the only tumor of the mediastinum that has a pathognomonic symptom. The Chinese woman quoted by Eloesser would not have spent two years in a sanatorium in consequence of repeated hemoptysis, presumed to be due to a small tuberculous focus at the hilus, if more attention had been paid to her husband's statement that she occasionally spit up hairs.

The physical examination may or may not reveal the presence of disease. In the absence of roentgenologic support, physical signs are open to misinterpretation. Numerous instances are recorded of mediastinal cysts being mistaken for pleural effusions, encysted empyemas, bronchiectasis, phthisis and other conditions. When once infection of a cyst has occurred, the resemblance to an empyema is close: the toxic appearance with high fever and clubbing of the fingers associated with signs of fluid in the chest has often led the physician to seek surgical aid. But even rib resection and drainage do not necessarily reveal the true nature of the condition. Before metastases are evident and cachexia supervenes it is often impossible to distinguish between a benign and a malignant tumor of the mediastinum, although to do so early is important. Two points of value in forming an opinion have been pointed out by Harrington (*Surg, Gynec & Obst* 51: 647 [Nov.] 1930). A benign tumor of the mediastinum may attain a large size without causing any pain. But a small malignant tumor may produce great pain. Secondly, Horner's syndrome occurs more frequently in malignant than in benign tumors.

Roentgenologic investigation is of the greatest service. A simple anteroposterior view usually is inadequate and tells little more than which side of the chest is affected. But when combined with a straight lateral view valuable information is obtained as to the shape and size of the tumor, whether its edge is clear cut or ill defined, homogeneous or nodular and—what is very important—whether the tumor lies in the anterior or the posterior compartment of the mediastinum. Oblique views often give a better idea of the structure to which the tumor is adherent. Screening may demonstrate pulsation. Roentgenologic examination combined with artificial pneumothorax may show the relation of the mass to the pleural space and whether it lies within or outside the lung substance. Contrast roentgenography with iodized oil is often useful. A complication by no means rare is secondary bronchiectasis. It is frequently difficult to decide whether certain symptoms such

as hemoptysis or thick purulent sputum, come from the cyst or the bronchiectasis to which it has given rise—a fact which is important from the standpoint of surgical treatment. It may be decided by comparison, with the sputum, of fluid withdrawn by tapping the cyst. If doubt still exists, injection of methylene blue into the cyst will disclose the presence of a bronchial fistula by tinting the sputum. Another way of solving the problem is by injection of iodized oil.

The National Health Campaign

At a reception held by the Central Council for Health Education at the London School of Hygiene and Tropical Medicine, the prime minister, Mr Neville Chamberlain, inaugurated the national campaign to encourage the wider use of health services. He described the gathering, at which many mayors and chairmen of county and district councils were present, as the largest one of responsible and influential members of local authorities that had ever been known. Great Britain was fortunate in having services and facilities for improving the health of the people which had not been surpassed by any other country in the world. But we had not succeeded in ensuring that those services were used to the full. Hence the need for this national campaign. We had antepartum clinics, infant welfare centers, tuberculosis dispensaries, facilities for the treatment of venereal diseases, school medical and dental services and our milk in schools scheme. We were adding to these services every year. Within the last few months we had made arrangements that qualified midwives on a whole-time salary basis would be available for attendance on women in their own homes.

Already encouraging results had been achieved. In the last fifty years the standardized death rate had been brought down from 187 to 92 per thousand, the infant mortality rate from 138 to 59 and the tuberculosis mortality from 2,450 to 657 per million. The expectation of life of a new-born child today was nineteen years longer than it was when Mr Chamberlain was born. But although tuberculosis was a notifiable disease, many cases were brought to the notice of the health officer in the later stages. The figures for children who attended infant welfare centers varied enormously. In some areas the whole infant population attended, in others the attendance was as low as 10 per cent. The same variation held for expectant mothers receiving antepartum care. Another striking instance of disregard for health was the scheme under which children could buy milk in the schools for half the ordinary price. School medical officers testified to the good effects of milk in improving the physique. Yet, leaving out the children who received free milk, less than half of the remainder bought it at the reduced price. The government and the Central Council for Health Education would therefore carry on for the next six months an intensive campaign of publicity and propaganda, in cooperation with the local authorities, who had responded to the project with the greatest enthusiasm.

The Progress of Cremation

Fourteen countries were represented at the International Cremation Congress, which has been held in London. In welcoming the delegates the lord mayor referred to the growth of cremation, which though one of the oldest forms of disposing of the dead dates in its modern form in this country from 1874. Lord Horder, who was elected president of the congress, said that its primary purpose was to establish a permanent international federation. The cause of cremation in many countries still suffered from legal restrictions. Cremation offered the only practical alternative to the prevailing system of burial, which was wasteful of ground, pagan in its perpetuation of the fetish of the physical body, criminal in its slipshod methods of registration, whereby it was possible for a death certificate to be given without the physician having seen the body, offensive in subjecting the body to the revolting process of

putrefaction, and menacing to public health in the danger of infection which clung to the soil. In this country, where every acre was precious, burial had become a luxury which we could not afford. To those who urged that cremation would give an impetus to crime he would point out that since the opening of the Woking crematorium upward of 100,000 persons had been cremated in this country, and in not one case had any suspicion of crime arisen.

PARIS

Oct 2, 1937

A Symposium on Pulmonary and Abdominal Infarcts

At the July 5-7 joint meeting of the Royal College of Surgeons and Académie de chirurgie, the program included the presentation of experimental and clinical study of infarcts of various viscera by members of the Académie de chirurgie.

Prof Raymond Gregoire reported his work on intestinal infarct. He objected to the use of the term infarct, which is the result of an arterial or venous obstruction. He had provisionally applied the term "inexplicable infarct" to the peculiar bluish or black discoloration seen on the exposed coils of intestine which disappeared immediately after a subcutaneous injection of epinephrine had been given in his first case. Some of his conclusions are reported in an article which appeared in the *International Journal of Surgery*. This type of "inexplicable infarct" forms in a few seconds without any vascular obstruction, hence he preferred the term "apoplexy" to that of infarct. The "apoplexy" may be hemorrhagic or edematous. Instead of being the result of a vascular obstruction, it is the result of such an intensive vasodilatation that it leads to rupture of capillaries and venules. This has led to the use, at least for intestinal and pancreatic "apoplexy," of epinephrine to act as a vasoconstrictor.

The idea that visceral apoplexies were of humoral origin resulted from the observation of a case which presented the clinical picture of acute ileus. A dark colored loop of bowel about 2 feet long, presented when the abdomen was opened. The normal color reappeared immediately after 1 mg of epinephrine had been given subcutaneously. The patient died eighteen months later of a cerebral hemorrhage. Dr Lerat of Brussels operated in a similar case and the patient died six months later, from a cerebral hemorrhage. In his later communications, Gregoire had called attention to the fact that the intestinal infarct observed by him was a local manifestation of an anaphylactic shock just as occurred in infarcts of other abdominal viscera. The question arose as to how such an "intolerance shock" could produce hemorrhagic exudates. It was found that all forms of irritation of the neurovegetative system cause a dilatation of the capillaries, which can progress up to the point of rupture with infiltration of the tissues with blood. Hence visceral apoplexy is the result of stasis by vasodilatation due to irritation of the neurovegetative system. The sequels are gangrene and perforation of the viscus. The indications for treatment are, first, to combat the shock, and second, to operate as soon as possible to note the degree of damage to the individual viscus. Since a paresis of the capillaries is the primary change, a vasoconstrictor in the form of epinephrine is indicated. If the exposed coil of intestine immediately regains its normal color, it can be replaced. If the return of circulation is questionable, the coil should be exteriorized. If the coil is already black, only resection or enterostomy is of any avail.

The second paper was by Prof Pierre Duval, on postoperative pulmonary infarct. There are two varieties, from the standpoint of pathology, a true form, i.e., with vascular occlusion, and a second without such occlusion, which it is advisable to term "apoplexy." The latter had been studied experimentally by the physiologist Prof Leon Binet and by himself. The

classic form presents the symptoms of sudden severe pain in the chest, bloody expectoration and local physical changes. Following operations under local or general anesthesia, a search for the cause of this "apoplexy" type of postoperative pulmonary infarct, experiments on dogs were undertaken to determine whether a generalized toxemia did not occur as the result of toxic products formed in the tissues devitalized during any operation. Polypeptides obtained from dog muscle were injected intravenously into dogs, or the muscles of cats. Dogs were crushed, thus releasing polypeptides into the general circulation. Three weeks later these dogs, sensitized to the toxic products of their own or homologous tissues, were given a second injection of polypeptides from dog's muscle. The series of injections was not followed by any pulmonary lesion, but in all the sensitized animals gross and microscopic examination revealed localized foci of hemorrhagic exudation in the pulmonary alveoli. The complete resemblance of these experimental lesions to those observed in human beings has been demonstrated in a case of Cadenat. Thus the pulmonary postoperative apoplexies belong in the group of visceral apoplexies first described by Gregoire. Perhaps the comparative rarity of such complications postoperatively is due to a lack of autogenous sensitization, which many patients possess before operation.

The third paper was by H. Mondor on uterine infarct. He had observed this lesion in thirty cases following death from abortion. Other cases have been reported by Drs Senegre, Huet and Ameline of Paris. The clinical picture is a typical one. Often following the intra-uterine injection of soapy water there follow signs of shock and of generalized toxemia. The uterus is enlarged and tender. The latter condition is also true of the adnexa. On vaginal examination with the speculum, the patches of cyanosis on the cervix are striking. At operation the uterus is found to be very dark or purplish with or without accompanying intense congestion of the adnexa and a blackish infiltration of the parametria. In a recent case in which operation was done very early by Patel and Esquerdan an opportunity was given to study the lesions in their incipience. No bacteria were found, only a thrombosis, both arterial and venous with intravascular hemolysis. The most typical finding in all of the cases, according to Mondor, is the erythrodiapedesis. Infection does not play any part in the process. Soap is a protoplasm poison and causes hemolysis, hence it can give rise to thrombosis without infection and an erythrodiapedesis without preceding thrombosis. The pathogenesis is still being studied. Intoxication of the splanchnic sympathetic can be caused by soapy water, by horse or human serum. Sensitization of animals, followed by typical infarct symptoms.

Infarct of the pancreas was the subject of the final paper, by Drs Pierre Brocq and Jacques Varangot, who pointed out that it is difficult in experimental work to imitate conditions found in pathologic conditions of the human pancreas. Although the authors recognized the interest and the importance of local anaphylaxis as reported by Gregoire and by Couvellaire, they thought that such a theory was not beyond criticism according to their own clinical and experimental observations. The experimental work of Reilly of Paris, although as yet uncontested and even if it shows an abrupt modification of cellular permeability, has as yet not been able to produce an acute necrosis of the pancreas without being associated with infarctions of other abdominal viscera. There are still many unknown factors to discover in acute pancreatic pathology. Epinephrine, ephedrine and general anesthesia (Gregoire) relieve the pain in acute pancreatitis, even if they do not check the anaphylactic changes. To check the pancreatic secretions atropine and gastric lavage with a solution of sodium bicarbonate have been given. The administration of physostigmine solution of sodium chloride and insulin controlled by frequent blood sugar estimations are indispensable. In France experi-

tory laparotomy is extensively employed, to avoid overlooking other lesions resembling acute pancreatitis clinically. Some surgeons believe that drainage of the necrotic areas and of the abundant pancreatic secretion is of value.

Socialized Medicine Decreases Number of New Medical Students

The annual report of Vienna University, published each year at the beginning of the winter semester, contains figures on the distribution, nationality and vocational bent of the students and graduates. During the last year (1936-1937) covered by the report, 1,430 students (about one third of them women) received the doctor's degree in the regular manner from one of the four faculties (law, medicine, philosophy and theology). For seven years past the number of newly graduated doctors has exhibited a steady year to year increase. In 1930, 965 persons received the doctorate and since then the rate of increase has been around seventy each year. One is struck by the interesting fact that the distribution of graduates among the various faculties has remained almost uniform. The law school conferred annually about 40 per cent of all doctoral degrees, the medical and philosophical faculties about 30 per cent each, whereas only some twenty theologians were graduated each year. Only in this last year does there appear an increase in the number of newly graduated doctors of medicine and this is proportionately greater among women physicians. But statistics with respect to medical undergraduates present a quite different picture. Among the total student population of nearly 9,000 there are 3,466 medical students, including 718 women. For the first time in many years a decline in the number of newly matriculated students of medicine is plainly observable. This is an obvious consequence of the bad prospect presented by the medical profession in Austria. Private practice here is being rapidly and steadily ruined by socialized medicine, which offers the population medical services at smaller cost. Furthermore, no appreciable numbers of first year students from eastern and southern Europe (the Balkans) matriculated during 1936-1937. Among the causes for this decline should be mentioned the rule that no foreign (non-Austrian) freshmen may be admitted until ample accommodation has been made for all Austrian freshmen in the laboratories, anatomy classes and so on. If the classes are not filled up by Austrian students foreign students may be admitted. (This rule does not apply to the graduate classes.) The foregoing measure was particularly necessitated by the steady decrease in the number of cadavers available for classes in anatomy and the shortage of space both in the school of anatomy and at the Institute of Physiology and Chemistry. Moreover, the faculty of medicine lacks funds for the construction of larger quarters. Political and religious motives may also underlie this restriction on foreign matriculants; it may be directed against an influx of students from Poland, Hungary and Rumania.

Proposed Revision of Austrian Insanity Laws

The Vienna Psychiatric and Neurologic Association appointed a committee to study the problem of revised insanity laws for Austria. Prominent in the legislative program sponsored by this group is the establishment of state detention institutions for psychopaths who, although not insane within the legal definition are nevertheless a public menace. At present Austrian hospitals for the insane have been conducted as institutions for the sick rather than as places of "detention." Professor Berze in a lecture before the association pointed out that from among psychopaths of the "borderline" type who, in the absence of any definite mental disease, cannot be declared insane are recruited those numerous mentally subnormal criminals who constitute a permanent social menace. If one of these persons

is convicted of an offense he may perhaps receive a light punishment or be placed under observation in a psychiatric institution for a time, then soon released as "not insane" to prey upon society. And this occurs even if the person presents an obvious picture of moral insanity. Under existing Austrian laws, both federal and local, it is impossible to place a criminal of the "borderline" type in permanent detention as the hospitals for the insane are filled to capacity with genuine mental cases. The Vienna psychiatrists recommend not only the "detention" of dangerous psychopaths but a continuous systematic psychiatric supervision of all psychopathic persons. This would assure special legal protection of the noncriminal psychopaths as well. The foregoing legislative reforms should be so implemented as to prevent criminal behavior on the part of psychopathic persons and thus provide truly adequate protection to the public. Any abnormal person who believes that some one has wronged or offended him and who accordingly utters threats, can, under the proposed legislation, be rendered harmless before he has had time to make good his threats. It is hoped that the collaborating jurists and psychiatrists will arrive at some appropriate middle ground between the principle of personal liberty and the conditions mentioned.

Admission to the Public Hospitals

The question of the admission of nonindigent patients to the public hospitals was placed on the agenda of the twenty-ninth *Congres de medecine professionnelle* by the Bureau of the *Federation medicale belge*. Mr. de Melinne made it the subject of his report and ended his summary of the situation with the following conclusions:

PUBLIC HOSPITALS

'Considering that public hospitals are, according to the terms of legislation pertaining thereto and the tenor of ministerial pronouncements, designed exclusively for the accommodation of persons who are indigent or public charges,

Considering that the legislative and ministerial regulations are frequently violated by the easily effected admission to public hospitals of nonindigent patients,

'Considering that these numerous and frequent abuses reflect unfavorably on the reputation of the medical profession in general and of those physicians who are serving on the staffs of hospitals, in particular,

The following remedial measures are herewith recommended: reestablishment of a rigorous, compulsory preliminary investigation of all patients who seek admission to a public hospital, this procedure to apply to the treatment of outpatients in the polyclinics as well as to patients who require hospitalization. Supervision of this sort ought to prevent the expenditure of public relief funds for the care of persons able to pay and nonindigent members of the sick insurance clubs, the medical care of whom is underwritten by these organizations. So far as is practicable, every public hospital should contain a section for paying patients wherein the customary rules with regard to choice of a physician and amount of honorariums would apply.

UNIVERSITY HOSPITALS

Resolved that the services of university hospitals ought, like all other hospital services directed by the Public Relief Commission to be primarily reserved for the indigent and semi-indigent sick in accordance with the letter of the statutes and ministerial pronouncements.

Considering how vitally important is the maintenance of a spirit of sincere collaboration between the heads of the various university services and the medical corps as a whole and granting that a university must be guaranteed a sufficient quota of

patients for clinical educational purposes, it is still, however, highly desirable that the commercial rivalry between the relief board and the medical corps should be abolished.

"It is recommended that a strict, compulsory, preliminary investigation be made of any patient who seeks admission to the university hospitals.

"As to medical educational needs, while it is conceded that bona fide members of insurance clubs (who come under the legal definition and who are accordingly not to be confused with insured persons in good circumstances) should be able to receive treatment at the university services, it is recommended that the benefits obtained by these true sick insurance club members should strictly coincide with the scale of sick benefits as customarily contained in the insurance contracts in the particular locality."

The Regulation of Masseurs

Messrs Dam, De Munter and Ledent called the attention of the Societe belge de physiotherapie to the undesirable features of the present system, under which any person no matter how deficient in technical and scientific qualifications can practice as a masseur. Numerous cases were cited in which incompetent masseurs were responsible for accidents to the patient. The authors believe that all persons who wish to practice medical massage should be compelled to undergo a certain prescribed course of training. Successful candidates in the examinations would be awarded certificates of authorization to practice massage. The authors also submitted detailed legislative proposals for the regulation of masseurs.

RIO DE JANEIRO

July 15, 1937

Congress of Orthopedics and Traumatology

The second Brazilian Congress of Orthopedics and Traumatology was held in Rio de Janeiro in July. Well known surgeons of the United States, Germany, Argentina and Uruguay were present at the congress, which was organized by the Sociedade Brasileira de Orthopedia e Traumatologia of São Paulo. Drs Achilles de Araujo and Milton Weinberger were president and secretary, respectively, of the congress. Dr Fred H. Albee of New York was the honorary president. The articles presented by foreign surgeons and discussed were the following: The importance of the lever at the top of the femur as a stabilizing influence and its restoration, Dr Fred H. Albee, congenital gibbosity and spine fusion and diseases of the osseous system by Prof Bruno Valentin of Germany, technic and new instruments for nailing fractures of the neck of the femur and results of nailing, Prof Henrique Lagomarsino of Argentina, Treatment of humeral supracondylar fractures, Dr Jose Luiz Bado of Uruguay.

The second official topic of the congress was "Fracture of Neck of Femur." The afternoon session was presided over by Prof Rezende Puech. Pernambuco is the city selected for the third Congress of Orthopedics and Traumatology. Profs Barros Lima and Bruno Maia were appointed president and secretary, respectively, of the coming congress. Official topics will be the treatment of sequels from acute anterior poliomyelitis and fractures of the malleolus. Drs Correa do Lago, Orlando de Souza, Godoy Moreira and Achilles de Araujo are the appointed official speakers.

Virus of Rural Yellow Fever

Dr Lucas de Assumpção lectured recently to the Sociedade de Biologia of São Paulo on work carried out at the Instituto de Hygiene of São Paulo. The work is concerned with the identification of the virus of a type of yellow fever, cases of which developed in rural areas of São Paulo and are not transmitted by *Aedes aegypti*. The speaker pointed out the differ-

ences of yellow fever according to its transmission by *Stegomyia* or without interference of the latter. He studied the blood of twelve patients. The blood was collected from suspected cases by the committee against yellow fever of the department of public health of São Paulo. In five blood samples the virus was identified. Three strains of the virus were dried and kept. They include the viruses of the Rocinha, Parnaíba and São types. The Rocinha strain is also maintained in mice.

Scholarships for Brazilians in the United States

The John Simon Guggenheim Memorial Foundation allows scholarships to students wishing to perform research work at university studies in the United States. The scholarships have been given, up to the present, to students from Chile and Mexico. Dr Henry Allen Moe, secretary of the foundation, recently stated that Brazilian students would have been included in the benefits of the scholarships since 1929 had it not been for the depression. Now that the depression is over, some of the scholarships will be given to Brazilians. A scholarship amounts to \$2,000 a year, which is given by the Guggenheim Foundation to the students for one year and then renewed for one or two more years. The money is given in advance to research workers or to students who wish to do research work or study in the universities of the United States.

Action of Coffee on Basal Metabolism

Dr J. Ribeiro do Valle, in a recent lecture delivered to the Sociedade de Biologia of São Paulo discussed the action of coffee, with or without caffeine, on the basal metabolism. Coffee, as generally prepared in Brazil, contains 2 mg of caffeine for each kilogram of coffee and it raises the basal metabolism. The speaker determined the basal metabolism by means of the Benedict-Roth apparatus on six normal persons. The calculations were based on the Aub-Du Bois formula. The determinations were made at intervals of thirty, sixty, ninety or 120 minutes in different cases, after ingestion of coffee which contained 0.18 per cent of caffeine and was sweetened with saccharin. The average elevation of the basal metabolism, two hours after injection of coffee, was 65 per cent. The administration of coffee which contains the mentioned quantity of caffeine does not induce changes of the pulse and temperature. In five of the six cases observed by the speaker the arterial pressure increased within 4 and 6 mm of mercury. Two persons in the group were given, on another occasion, coffee without caffeine. The basal metabolism slightly increased in one case and lowered in the other one. The results of the speaker's studies agree with those reported by Meyer, Horst and collaborators. Precise conclusions on the subject cannot as yet be established.

Reorganization of the University of Brazil

A law for the reorganization of the University of Brazil and construction of the University City at Rio de Janeiro recently passed the House of Deputies. The federal government is now in charge of the construction of University City, which will cover a large area near the Boa Vista village and will include the faculties of philosophy, education, fine arts, engineering, mining and metallurgy, chemistry and pharmacy, law, politics and economics, agriculture, veterinary medicine and music. There also will be a hospital.

Homage to the Memory of a Nurse

A bronze plate was recently dedicated at the São Sebastião Hospital of Rio de Janeiro to the memory of Maria da Conceição Lopes, a Brazilian nurse who died a victim of her work. The plate was presented by a representative of the government and it was donated by the Association de Enfermeiros e Enfermeiras de Ayuda Mutua of Buenos Aires. During the ceremony, Dr Sinval Lins, the director of the hospital, made a speech on the heroism of Miss Lopes in her professional duties. Dr Deodoro Lopes, a brother of Miss Lopes, thanked the Argentine

sociation of nurses, the Argentine government and their representative as well as the Brazilian government for the homage paid to the memory of his sister

New Hospital

The Carlos Chagas Hospital of Rio de Janeiro was recently opened. Many persons attended the inauguration ceremonies, during which the governor of the Federal District made an address to the memory of Carlos Chagas

Sept 30 1937

Medical Society Reunion

The Accademia Medica of Rome met recently under the chairmanship of Prof Roberto Alessandri. Professor Jura spoke on the postoperative variations of water in the blood following colonic and parenteral administration of water. The amount of water in the blood increases 2 or 25 per cent after administration of water in surgical interventions. It increases more than that in patients suffering from liver disorders. When the amount of water in the blood is high before a surgical intervention, it may increase to 8 per cent after it. Bang's method for quantitative determinations of water in blood is the most exact.

Professor Baglioni of the University of Rome said that the water in the blood is almost a fixed constant in persons subjected to experimental conditions even if they drink large amounts of water through induced thirst. The laws of the water metabolism are related to the amount of water in the blood, intestinal absorption, emunctory functions of the kidney, lung, skin and intestine and the amount of water in the interstitial lymph and the tissues.

Professor Cappelli said that the blood of patients suffering from cancer is in a condition of qualitative dysglycemia which makes favorable conditions for the exaggerated multiplication of cancer cells. Subcutaneous injections of soluble sulfates cause an acceleration of the consumption of dextrose as well as modifications of the terrain by which the exaggerated multiplication of abnormal cells is restrained and the development of the primary tumor arrested or regressed.

Professor Jura reported results of studies on the variations of the erythrocytes in the blood of dogs after experimental intestinal resection. Following resection of the small intestine in one fifth, one fourth or one third of the total length of the structure, anemia develops. From his experiments the speaker points out that Castle's antianemic factor probably exists in the intestine as it does in the stomach and duodenum.

Prof Gino Meldolesi and W Siedel said that the elimination of bile pigments is increased in patients suffering from myopathies. By using a chromatographic method they determined special pigments in the feces, which are fluorescent to zinc and different from stercobilin and urobilin. They seem to be the terminal product of disintegration of myoglobin. The latter which has a special spectrum, is present in muscle serum of patients suffering from myopathic diseases, whereas from the blood serum and bile of the same patients abnormal pigments can be determined.

Professor Meldolesi said that chromatography which is in common use in analytic chemistry, can be applied to clinical research, purification of substances for analysis the procurement of pigments directly from the blood, bile and feces separation of myoglobin from hemoglobin for later crystallization of myoglobin and examination of normal and pathologic biliary pigments.

Professors Meldolesi and De Orchi studied the behavior of striated muscles in the course of diphtheria scarlet fever, typhus and pneumonia by means of biopsy and chronaximetric methods. In many cases they found precise muscular altera-

tions which are associated with disorders of the metabolism of the glucides and the creatine bodies. The myoglobin metabolism is normal in cases which follow a common evolution. In grave cases with fatty degeneration the myoglobin metabolism is disturbed and the pigment leaves the muscle and causes the appearance of Fischer's second K substance in the feces. In cases of this type persistent muscular alterations take place which induce static and dynamic modifications that are associated with the development of permanent grave changes of the myocardium.

Death of Francesco Della Valle

Dr Francesco Della Valle, lieutenant general of the army and formerly surgeon general in the Italian army, died recently at Puccianello in Caserta. Dr Della Valle was internationally known in the military medical circles. During the World War he was the organizer of surgical ambulances which were placed in charge of university clinicians. By the establishment of quarantine hospitals the country was protected at that time against contagious diseases. Dr Della Valle was president of the second International Congress of Military Medicine and Pharmacy which was held in Rome in 1923. Later he was appointed honorary president of the International Permanent Committee of Military Sanitation. During the time he was surgeon general, this sanitary organization was given the silver medal for the health crusade carried on from 1915 to 1918 and also the gold medal for work in public health.

Marriages

FREDERICK MACDONALD RICHARDSON, Haddonfield N J, to Miss Margaret Jane Ullom of Philadelphia, August 14

WILBUR CURTIS HUNSLCKER, Goldsboro, N C, to Miss Helen Marie McKown in Blackstock, S C, July 5

DAVID DUDLEY STEPHENS, Slocumb, Ala, to Miss Berta Napier of Dothan, in Marianna, Fla, July 22

GEORGE PARROTT ROSEMOND, Kingston, N C, to Miss Lois Jean Mason of Cynwyd, Pa, August 21

FRED M DUCKWALL to Miss Mary O Pinkston, both of Kingsport, Tenn, in Knoxville, July 6

ARTHUR EITEL BOYSEN, Pharr Texas to Mrs Ruth Mildred Funk of Superior, Neb, February 27

MARION TIMOTHY FLYLER JR, Durham, N C, to Miss Alma Odell Blanchard at Gatesville, July 31

LUDWELL F LEE, Passapatanzy Va, to Miss Mary Nell Woolfolk of Bowling Green, July 30

PHILIPS JOHN CARTER, New Orleans, to Miss Mildred Gutreau of Gainesville, Fla July 8

ROGER O DONNELL JR, Washington, D C, to Miss Blanche Rene Simmons of Boston August 7

LOREN F WASSON, Chicago City, Minn, to Miss Helen F Brohaugh of Minneapolis, recently

EDWARD J EDELEN JR, Washington, D C, to Miss Mary Keech at Brantown Md, July 27

FRANCIS NEWBY MULLIN JR to Miss Frances Tucker Taylor, both of Norfolk Va August 4

JAMES WILLIAM ELLIOTT to Miss Frances Love Jackson, both of Lebanon Va, in August

GLEN WARD PHIPPS, Galva, Va, to Miss Frances Grayber of Christiansburg June 30

MARVIN F WEISSMAN, Milford, Ill, to Miss Olive Maxwell of East Moline recently

ALLEN G CALDWELL to Miss Isabella Thomas both of Covington Ky, in July

ROBERT DRANE, Savannah Ga, to Mrs Naomi Everett Gore in New York July 10

IRVING RAFFOGEL to Miss Ruth Natalie Fried both of New York September 29

WILLIAM C GORDON to Miss Stella D Fain, both of Brooklyn September 19

LIVAN M MCBRYDE to Miss Ruth Fennell both of Detroit September 6

Deaths

Walter Jarvis Barlow • Los Angeles, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1892, first Vice President of the American Medical Association, 1911-1912, and chairman of the Section on Practice of Medicine, 1912-1913, past president of the Los Angeles County Medical Association, founder of the Barlow Medical Library, formerly vice president of the National Tuberculosis Association and secretary-treasurer of the California Tuberculosis Association, at one time dean and professor of medicine at the University of California College of Medicine, member of the American Clinical and Climatological Association, during the World War served with the American Red Cross, and with the Veterans Bureau, remaining an examining and consulting physician with the bureau until 1924, director of the Barlow Sanatorium, on the staffs of the Los Angeles County Hospital and the Hospital of the Good Samaritan, aged 69, died, September 3, of bronchopneumonia.

James Nathaniel Jenne • Burlington, Vt., University of Vermont College of Medicine, Burlington, 1881, member of the House of Delegates of the American Medical Association in 1908, 1910 and 1929, dean at his alma mater, and at various times professor of therapeutics and clinical medicine, professor and adjunct professor of materia medica, past president of the Vermont State Medical Society and the Chittenden County Medical Society, veteran of the Spanish-American War, consulting physician to the Mary Fletcher Hospital, consulting surgeon to the Bishop De Goesbriand Hospital, Burlington, and the Fanny Allen Hospital, Winooski, director of the University of Vermont College of Medicine Dispensary, formerly member of the board of trustees of the University of Vermont, aged 77, died, September 9.

H Beattie Brown • Saranac Lake, N. Y., College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1890, past president of the Franklin County Medical Society, member of the American Laryngological, Rhinological and Otolological Society, formerly assistant professor of otology at the New York Post-Graduate Medical School, Columbia University, New York, for many years on the staff of the Manhattan Eye, Ear, Nose and Throat Hospital, New York, past president of the Westchester County Medical Society, on the staff of the General Hospital of Saranac Lake, member of the advisory board during the World War, aged 74, died, August 13, of coronary thrombosis and arteriosclerosis.

David Harrower • Worcester, Mass., Harvard University Medical School, Boston, 1884, member and past president of the American Ophthalmological Society, member of the American Otolological Society and the New England Ophthalmological Society, fellow of the American College of Surgeons, consulting ophthalmic and aural surgeon to the Worcester City, Memorial, St. Vincent and Fairlawn hospitals, Worcester Hospital Cottages for Children, Baldwinville, Milford (Mass.) Hospital, Holden (Mass.) Hospital and the Peterborough (N. H.) Hospital, aged 80, died, August 7, of chronic nephritis, duodenal ulcer and uremia.

James Pleasant Matheson • Charlotte, N. C., University of Maryland School of Medicine, Baltimore, 1905, member of the American Academy of Ophthalmology and Oto-Laryngology and the American Laryngological, Rhinological and Otolological Society, fellow of the American College of Surgeons, served during the World War, otolaryngologist to the Charlotte Eye, Ear and Throat and Presbyterian hospitals and the Charlotte Sanatorium, aged 58, was killed, August 5, in an automobile accident, near Hartsville, S. C.

Edward King Root • Hartford, Conn., University of the City of New York Medical Department, New York, 1879, secretary of the Public Health Council 1917-1929, member of the state board of health, 1899-1917, member of the city board of health 1893-1899 and 1904-1907, medical director of the Aetna Life Insurance Company 1899-1933 on the staff of the Hartford Hospital and the Hartford Retreat for many years, aged 79, died, August 12, of heart disease at his summer home in Fenwick.

Carl M. Anderson • Rochester, Minn., Milwaukee Medical College, 1911, assistant professor of otolaryngology and rhinology at the University of Minnesota Graduate School of Medicine, member of the American Academy of Ophthalmology and Oto-Laryngology and the American Laryngological, Rhinological and Otolological Society, consulting physician, section on otolaryngology and rhinology, Mayo Clinic, served during the World War, aged 55, died, August 10, of coronary thrombosis.

John Jenkins Buchanan • Pittsburgh, University of Pennsylvania Department of Medicine, Philadelphia, 1881, emeritus professor of surgery, University of Pittsburgh School of Medicine, past president of the Allegheny County Medical Society, member of the American Surgical Association, fellow of the American College of Surgeons, on the staff of the Mercy Hospital, aged 81, died, August 24.

Fletcher Burr Taylor, Kansas City, Mo., University of Kansas School of Medicine, Kansas City, 1908, member of the Missouri State Medical Association and the American Urological Association, served during the World War, aged 50, on the staffs of the Research Hospital, General Hospital at St. Luke's Hospital, where he died, July 15, of chronic myelogenous leukemia and heart disease.

Charles Meade Thomas, Sunbury, Pa., Jefferson Medical College of Philadelphia, 1910, served during the World War, formerly on the staff of the Mary Packer Hospital, aged 49, died, July 18, of a compound, comminuted fracture of the right tibia and fibula and left fibula, sustained in an automobile accident three years ago, and septic arthritis.

Arthur Otway Peters • Dayton, Ohio, Northwestern University Medical School, Chicago, 1904, past president of the Montgomery County Medical Society, city health officer, editor of the bulletin of the division of health, aged 60, on the staff of the Miami Valley Hospital, where he died, August 6, of cerebral embolism.

Samuel Halcomb Behrend Basch, New York, Albany (N. Y.) Medical College, 1903, member of the Medical Society of the State of New York, on the staffs of the Fordham Hospital and the Manhattan Eye, Ear, Nose and Throat Hospital, aged 55, died, August 5, of coronary occlusion and arteriosclerosis.

George Henry Brinkman, Oneonta, N. Y., University of the City of New York Medical Department, 1888, member of the Medical Society of the State of New York, on the staffs of the Parshall Private Hospital and the Aurelia Osborn Fox Memorial Hospital, aged 73, died, August 2, of myocarditis.

Benjamin Franklin Buzby, Swedesboro, N. J., University of Pennsylvania Department of Medicine, Philadelphia, 1887, past president of the Gloucester County Medical Society, aged 81, on the staff of Haffey's Private Hospital, where he died, August 5, of coronary thrombosis.

Siegfried Spies, Davenport, Iowa, Albert Ludwigs Universität Medizinische Fakultät, Freiburg, Baden, Germany, 1934, Universität Basel Medizinische Fakultät, Switzerland, 1935, aged 26, intern at the Mercy Hospital, where he died, July 2, of hemorrhagic jaundice.

James Henry Downey • Gainesville, Ga., Atlanta Medical College, 1887, member of the Southeastern Surgical Congress, fellow of the American College of Surgeons, on the staff of the Downey Hospital, aged 72, died, August 28, in the Crawford W. Long Hospital, Atlanta.

S. B. Smith, Walnut Grove, Mo., Missouri Medical College, St. Louis, 1896, also a druggist, formerly director of the school board, aged 65, died, July 14, in St. Mary's Hospital, Rochester, Minn., of cirrhosis of the liver and gallbladder disease.

Charles Daniel Steenken • Salisbury, Md., Columbia University College of Physicians and Surgeons, New York, 1896, medical superintendent of the Maryland Tuberculosis Sanatorium, aged 66, died, July 29, of angina pectoris.

Francis Gustavus Swedenburg • Ashland, Ore., Rush Medical College, Chicago, 1900, fellow of the American College of Surgeons, on the staff of the Community Hospital, aged 69, died, July 31, of mediastinitis and pulmonary gangrene.

Oscar Corwen Payne, Humboldt, Kan., Lincoln (Neb.) Medical College of Cotner University, 1903, served during the World War, owner of an emergency hospital bearing his name, aged 68, died, July 31, in Wichita of arteriosclerosis.

Emerit E. Jouett, Carrollton, Ill., Marion Sims College of Medicine, St. Louis, 1891, member of the Illinois State Medical Society, formerly member of the city council, aged 71, died, July 29, of carcinoma of the maxilla with metastases.

Thomas Judson Allison, Rio Grande, Ohio, Baltimore University School of Medicine, 1897, member of the Ohio State Medical Association, was president of the county board of health, aged 67, died, August 3.

John Edward Martin, New Britain, Conn., University of the City of New York Medical Department, 1892, formerly member of the school board, aged 73, died, July 17, in the New Britain General Hospital.

Belle Loomis Reynolds, Santa Barbara Calif, Hahnemann Medical College and Hospital, Chicago, 1880, served during the Spanish-American War, aged 96 died, July 28, of chronic myocarditis

Wilson Gill Bailey, Camden, N J, Jefferson Medical College of Philadelphia, 1891, member of the Medical Society of New Jersey, aged 71 died, August 2, of myocarditis and arteriosclerosis

Perry McSwain Judy, St George, S C, Medical College of the State of South Carolina, Charleston, 1881 also a druggist, formerly mayor, aged 79, died, July 21, of cerebral hemorrhage

John C Sossoman, Midland, N C, North Carolina Medical College, Charlotte, 1915, aged 56, died, July 18 in the Presbyterian Hospital, Charlotte, of appendicitis and peritonitis

Eugene Joseph Mioton, Fair Haven N J, University of Louisiana Medical Department, New Orleans, 1877, aged 79, died, July 19, of urinary calculi and hypertrophy of the prostate

John T Martin, Mount Ayr, Ind, Hahnemann Medical College and Hospital, Chicago, 1895, aged 70, died, July 10, at Promise City, Iowa, of erysipelas and chronic myocarditis

Alexander Peter Stewart, Biloxi, Miss, Homeopathic Medical College of Missouri, St Louis, 1883, aged 78, died, July 27, of hypertensive heart disease and chronic nephritis

James Edward Francis Henry Ⓢ Cranston, R I, College of Physicians and Surgeons, Boston, 1904, aged 59, died suddenly, July 6, of coronary occlusion and diabetes mellitus

Roland Hall Shippey, Wichita, Kan, Denver and Gross College of Medicine, 1903, member of the Kansas Medical Society, aged 63, died, in July, of portal cirrhosis

James M Sullivan, Hayesville N C Atlanta Medical College, 1886, aged 75, died, July 10, in the Piedmont Hospital, Atlanta, of hypertrophy of the prostate and uremia

Claude Woltz Ashburn, Pilot Mountain N C Washington University School of Medicine, St Louis, 1927, aged 33, was killed, August 14, in an automobile accident

Mary Augusta Killeen Ⓢ Dubuque, Iowa University of Michigan Department of Medicine and Surgery, Ann Arbor, 1904, aged 65, died, July 15, of endocarditis

Curtis Bruen, New York, Cornell University Medical College, New York, 1928, aged 32, was found dead, August 29 at Towaco, N J, of poison, self administered

Clayton Allen Brown, Redgate, Md Baltimore Medical College, 1897, aged 66, died, August 14 of coronary thrombosis, cerebral hemorrhage and arteriosclerosis

H Franklin Eames, Egg Harbor, Wis, College of Physicians and Surgeons of Chicago, 1889, aged 78, died July 30, of arteriosclerosis and cerebral hemorrhage

John E McMahan, Conway, Ark, University of Louisville (Ky) Medical Department, 1900, aged 77 died, July 31, as the result of an automobile accident

Robert Fendall Chapman Jr Ⓢ New York, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1895, died, July 1

Alfred John Peel, St Helens, Ore Western University Faculty of Medicine, London, Ont, Canada, 1895, aged 69, died, July 24, of coronary thrombosis

Millicent Lendora Hutchins, Los Angeles Hahnemann Medical College of the Pacific, San Francisco, 1903, aged 74, died, July 21, of chronic myocarditis

William Calvin Taylor Sr, Calvert, Texas, Memphis (Tenn) Hospital Medical College 1895, aged 72, was found dead, July 17, of coronary occlusion

Elstner H De Berry Ⓢ Hazlehurst, Miss, College of Physicians and Surgeons, Memphis, Tenn, 1907, aged 65, died suddenly, July 18, of heart disease

Rodman Ellison Sheen, Somers Point, N J Hahnemann Medical College and Hospital of Philadelphia, 1911, aged 47 died July 12, of pituitary tumor

Frank Jerome Collison Ⓢ Bluefield W Va, College of Physicians and Surgeons, Baltimore, 1888 aged 69, died, August 8 of acute pancreatitis

Thomas Jefferson Penn, Crandall, Texas University of Tennessee Medical Department, Nashville, 1890, aged 84 died, July 1, of bronchopneumonia

John Gilmore Neely, Winside, Neb State University of Iowa College of Medicine Iowa City, 1893, aged 71, died, July 7, of gastric hemorrhage

METRAZOL VERSUS INSULIN IN THE TREATMENT OF SCHIZOPHRENIA

To the Editor—With the hypoglycemic insulin and metrazol convulsant therapies of schizophrenia both already introduced into this country, the rivalry between the two forms of treatment that has already broken out in Europe will soon be carried to these shores. Physicians will be particularly interested in the effect of the controversy on actual therapeutic procedure.

The shock treatment was introduced by Sakel at a meeting of the Gesellschaft der Aerzte in Vienna, Nov 3, 1933. The official report of the society proceedings may be read in the *Wiener klinische Wochenschrift* for Nov 10, 1933. It is stated (page 1372) that the insulin shock treatment consists of the production of severe hypoglycemic shock with coma and epileptic seizures ('Erzeugung von schweren hypoglykämischen Schocks, eventuell mit Koma und epileptischen Anfällen durch hohe Insulindosen'). In the ensuing discussion, Prof Otto Poetzl, chief of the Psychiatric University Clinic, under whose supervision the work was done, declared that 'the essence of the treatment consists of the production of a very severe hypoglycemic shock with epileptic seizures ("das Wesen der Behandlung auf einen sehr schweren hypoglykämischen Schock mit epileptischen Anfällen beruht")'. In the report of the paper in the *Wiener medizinische Wochenschrift* for Nov 18, 1933, the phenomenon of shock is defined (p 1327) as "the production of an epileptiform or comatose condition by means of large doses of insulin ("Herbeiführung epileptiformen oder komatösen Zustände durch grosse Insulindosen")".

L von Meduna of Budapest, who sponsors the metrazol (called cardiazol abroad) convulsant therapy, states that he first began to experiment with camphor convulsions in guinea-pigs on Nov 23, 1933, while the report of this work (Ueber experimentelle Kampferepilepsie) was submitted to the *Archiv für Psychiatrie* in June 1934 and appeared in September of that year. Jan 2, 1934, he says, he produced his first camphor convulsion in a human being. His first report of the successful convulsant treatment of schizophrenia was submitted to the *Zeitschrift für die gesamte Neurologie und Psychiatrie* Jan 18, 1935, and published February 21 of that year.

Sakel, meanwhile, was continuing his work at the Psychiatric Clinic in Vienna, and his results were finally published at length in a series of articles in the *Wiener medizinische Wochenschrift* from Nov 3, 1934, to Feb 9, 1935. This series of papers, since published as a separate monograph ("Neue Behandlungsmethode der Schizophrenie," Vienna, Verlag Perles, 1935) is full of discussion of the epileptic type of reaction. On pages 9 and 10, for example, there are descriptions of the two types of reaction—the comatose reaction and the epileptic seizure. On page 12 the epileptic seizure is again mentioned as an example of a severe shock reaction. Epileptic seizures in the course of treatment are reported in the case histories and there are numerous references to the value of the seizure. I cite a few examples:

Pages 36, 74 and 88. Patient H, who suffered from catatonic excitement (case 7), suddenly became lucid after a severe epileptic shock ("Ich habe einen Fall beobachten können [siehe Fall VII], der schlagartig durch einen schweren epileptischen Schock aus einem schwer katatonen Erregungszustand lucid geworden ist.")

Pages 45 and 64. Patient B (case 2) became clear and composed, with full insight into his illness, after a seizure.

On page 109 another case is discussed in which recovery from psychosis followed a status epilepticus.

These observations have been confirmed by other workers (see, for example, *Arch Neurol & Psychiat* 38 192 and 195 [July] 1937 for similar experiences at Bellevue)

Sakel was, however, not the first to observe the beneficial effects of epileptic seizures on schizophrenic patients any more than he was the first to use insulin in the treatment of schizophrenia. G Muller (*Allg Ztschr f Psychiat* 93 233, 1930) recognized the beneficial effect of the epileptic seizure before him, but Sakel appears to have been first actually to induce a convulsion in the course of treatment of schizophrenia. The difficulty with the hypoglycemic insulin convulsion, though, was that it was usually unpredictable and not self limited, the hypoglycemic seizure not infrequently introduced further complications or a status epilepticus, so that hypoglycemia had to be terminated when it occurred. Sakel made some attempt to predict an impending seizure by clinical signs and there is, furthermore, evidence in his monograph that he used both camphor and metrazol intramuscularly to provoke seizures (see curve 7 on page 29 of the monograph) long before Meduna's reports were published. One gets the impression however that he at first rather overestimated the danger of seizures and later relied mainly on the hypoglycemic coma as such in the development of his method.

Meduna's work, however, now makes it possible to employ the epileptic seizure more easily for therapeutic purposes. Meduna has performed a twofold service by (1) developing a precise and effective method of producing seizures with intravenous administration of metrazol and (2) promulgating an attractive theory on the mutual incompatibility of schizophrenia and epilepsy. His sponsorship of the convulsant treatment, however, involves the claim that the epileptic shock is preferable to the comatose shock in the treatment of schizophrenia. It is too early to substantiate or disprove this claim. Meanwhile it need not be assumed that the treatments are altogether different and distinct or mutually incompatible. On the contrary, since the insulin treatment has from the beginning recognized and valued the efficacy of epileptic seizures, it must welcome and accept the metrazol-induced seizure as a significant step forward. The physician who finds a patient who benefits from seizures, who cannot develop suitable coma or who is resistant to coma will now be able to increase the frequency of convulsions in the course of treatment by using metrazol. It will be discovered in time whether the comatose reaction is dispensable. The only workers, Angyal and Gyárfás (*Arch f Psychiat* 106 1, 1936) who have so far reported on experiences with a large series of cases on metrazol and on insulin conclude that metrazol is indicated in certain cases but report several instances in which patients who were resistant to metrazol responded to insulin. If the exclusively convulsant treatment of schizophrenia by means of metrazol is in the long run to supersede insulin treatment, it must offer additional advantages than those of economy and simplicity.

JOSEPH WORTIS, M.D.

Bellevue Psychiatric Hospital, New York.

"PNEUMOTHORAX FROM EXPERIMENTAL OVERINFLATION OF THE LUNG"

To the Editor—Regarding your review entitled "Pneumothorax from Experimental Overinflation of Lung" of my address before the fourth Federative International Congress of Anatomists at Milan, Italy, which appeared on page 959 of THE JOURNAL of September 18, I wish to record my satisfaction with the manner in which my results have been presented.

Since the original paper was published I have found histologic evidence which confirms my former supposition that air from the overinflated region of the lung was leaking into the sheaths of the pulmonary arteries and veins through minute ruptures in the bases of those alveoli which overlie these sheaths. When a suspension of fine carmine grains in hot gelatin is injected into the previously overinflated part of the cat's lung immediately after the experimental production of pneumothorax and massive collapse, through the catheter used for the

air injection (which was allowed to remain in its former position), I have found in sections made after cooling and suitable fixation of the part that the carmine grains appear in accumulations on the aforementioned alveolar bases and give the impression that they have been filtered out as the gelatin passed from the alveoli, through minute ruptures in their bases into the sheaths of the blood vessels. Gelatin, for the most part showing few or no carmine grains, was found in the vascular sheaths, mixed with the air from the previous interstitial emphysema occasioned by the overinflation. Sometimes streams of carmine granules, leading from the overlying alveolar bases into the swollen vascular sheaths, were found, and these seemed to indicate the sites of ruptures of a size so large that the grains passed through them. These observations were communicated to the Anatomische Gesellschaft in a paper given at its meeting at Königsberg, East Prussia, August 25 and a full report of them will appear soon in the *Verhandlungen* of that society.

Professor of Histology and Embryology,
University of Western Ontario Medical
School

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT HOWEVER REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

PROGNOSIS IN TUBERCULOSIS

To the Editor—What is the death rate in pulmonary tuberculosis in cases classified as far advanced when first diagnosed? What is the life expectancy in pulmonary tuberculosis diagnosed as far advanced when first seen? What is the mortality rate following nephrectomy for renal tuberculosis for renal calculi for pyonephrosis and for renal malignancy? What percentage of patients with far advanced pulmonary tuberculosis die of complications such as acute disseminated miliary tuberculosis and tuberculous meningitis?

J C NEGLEY M D Glendale Calif

ANSWER—Occasionally a patient with far advanced pulmonary tuberculosis makes a complete recovery, but such occurrences are rare. It is not unusual for the patient with chronic advanced disease to enter on a period of remission and show improvement. Even most symptoms disappear and, so far as external manifestations are concerned, the patient seems well. However, the examination of the chest, including an x-ray film, reveals the fact that disease is still present and sooner or later the majority of such patients have exacerbations and finally die of tuberculosis. Cedric Shaw (*Quart J Med* 2 179 [April 1933]) has called attention to the poor ultimate prognosis when only sanatorium care is used. The majority of patients with pulmonary tuberculosis in the far advanced stage present cavities in their lungs, and cavitation usually justifies a poor prognosis.

In 1928 H L and Lena R P Barnes (*Am Rev Tuberc* 18 412 [Oct] 1928) reviewed 1454 cases of pulmonary tuberculosis with demonstrable cavitation. Eighty per cent of these patients were dead within a year from the time they were first seen, 85 per cent within three years, 90 per cent within five years and 95 per cent within fifteen years. Thus the ultimate prognosis of far advanced pulmonary tuberculosis is poor. The exceptional case belongs to the Barneses. 5 per cent alive fifteen years after the disease was detected. Such persons may have advanced tuberculosis with no significant external manifestations except cough and expectoration, which they attribute to bronchitis. They may work for years and die in senility only to have their advanced tuberculosis detected at the postmortem table. Almost every physician engaged in the field of clinical tuberculosis for a decade or more is able to cite a few instances of far advanced chronic tuberculosis with symptoms so slight as to incapacitate the patients little or not at all.

While sanatorium care alone usually accomplishes little for the case of pulmonary tuberculosis in the advanced stage, modern methods of treatment, particularly collapse therapy, often change the prognosis favorably. For example Bentley (Medical Research Council Special Report Series, No 215 His Majesty's Stationery Office London 1936) has recently

reported 677 cases treated by artificial pneumothorax in most of which moderate to far advanced disease existed when the treatment was begun. He compared them with a control group consisting of 3329 patients treated by the sanatorium method alone. At the end of five years, the survivals were 20 per cent more among the artificial pneumothorax group than among the control group. In fact, of the 2,013 males in the control group 1,443 were dead at the end of five years and of the 1,316 females in this group 896 were dead in five years.

Many patients with far advanced pulmonary disease cannot have artificial pneumothorax instituted because of the extent of disease in both lungs or the presence of adhesions, which prevent a satisfactory collapse. For those who have their disease confined largely to one lung either on the first examination or after a period of bed rest during which artificial pneumothorax is found impossible, chest surgery is often capable of closing cavities and materially improving prognosis. In fact, many persons are living and some are working in this country who, without such procedures as extrapleural thoracoplasty and paraffin packs, could not possibly have survived. Most persons with chronic pulmonary tuberculosis in the advanced stage have passed through a period of years when the disease was detectable by modern methods of diagnosis but when it caused no symptoms. It is only rarely that the disease becomes far advanced in a short period.

The mortality following nephrectomy for renal tuberculosis is 2 per cent or less (Wilbolz, *Hans J Urology* 21 145 [Feb] 1929). Nephrectomy for renal calculi carries a mortality of from 2 to 35 per cent. However, if nephrolithotomy is performed the mortality is 5 per cent in aseptic cases and 15 per cent in infected cases. When pyelolithotomy is performed, the mortality is 18 per cent in aseptic cases and 33 per cent in infected cases. The mortality is approximately the same when nephrectomy is done for pyonephrosis as in the case of renal calculi. The mortality following nephrectomy for tumor ranges between 5 and 15 per cent in adults and as high as 50 per cent in the infant. These mortality figures following nephrectomy are based on the results of the work of expert surgeons in this field.

Generalized miliary tuberculosis is caused by a focus of disease finding its way into a large lymphatic duct or a blood vessel. A common source of such disease is the lymph nodes of the hilar region. These nodes nearly always constitute a part of the primary tuberculous complex. They contain caseous material with a high tubercle bacillus content. When this material burrows through into a vessel, it feeds the blood stream with large numbers of bacilli. The chronic form of pulmonary tuberculosis usually does not increase the involvement of the regional lymph nodes of the hilus to any appreciable extent. Therefore there is little more likelihood of the patient with far advanced pulmonary tuberculosis developing miliary disease than the person who has only the primary tuberculous complex with no previous illness from the disease.

In fact, miliary tuberculosis is not an uncommon complication among infants who have developed the primary complex as manifested by the positive tuberculin reaction. Usually such infants have little or no evidence of disease in the lungs except the small primary focus but the hilar lymph nodes are definitely involved. Among infants who have been contaminated with tubercle bacilli there is considerable risk from miliary tuberculosis within three months after the primary complex develops.

Following this period the risk is decreased but there remains a possibility of the development of miliary disease as long as the hilar lymph nodes contain caseous foci, which may be for the remainder of the lifetime of the patient. Thus, apparently normal healthy individuals in all decades of life are seen who fall acutely ill and die in a short time of miliary disease. Many such persons never knew that the tuberculous primary complex existed in their bodies, but after illness appeared x-ray examination may or may not have revealed evidence of Ghon tubercle formation in the lung or calcium deposits in the hilar region. The postmortem examination reveals the true source of the miliary disease in one of the caseous regional lymph nodes, which had recently poured into the blood stream large numbers of tubercle bacilli. Among adult patients with chronic pulmonary tuberculosis, the incidence of generalized miliary tuberculosis is extremely small. It is usually not greater than 1 per cent.

Diffuse tuberculous meningitis has been proved by Rich and McCordock (*Bull Johns Hopkins Hosp* 52 5 [Jan] 1933) to be caused by a previously existing tuberculous focus in or adjacent to the central nervous system. It is probable that such foci are laid down in these parts by neutrophils, which focalize tubercle bacilli in various parts of the body soon after the first infection occurs. As in the lungs, these primary foci usually produce no significant symptoms and may lie dormant

throughout a long lifetime. Every one who has witnessed numerous examinations of the central nervous system at post-mortem has seen solitary tubercles which had nothing to do with death. However, such a primary focus constitutes a potential menace, for, like those in the lung or the hilar region, its caseous material may burrow through and the imprisoned bacilli escape. When located in and adjacent to the central nervous system, the bacilli may spread into one of the ventricles of the brain or directly into the subarachnoid space and there set up diffuse tuberculous meningitis. Here, as in military disease, the greatest danger appears to be within a period of three months after the primary foci are laid down (Wallgren, *Arvid J. Pediat.* 5:291 [Sept.] 1934). However, such foci in and about the central nervous system constitute a distinct danger to the host as long as they contain living tubercle bacilli. Thus in all decades of life, including the period of senility, persons who have always enjoyed good health suddenly fall ill and die of tuberculous meningitis, after which careful examination of the central nervous system reveals the presence of the old focus that was responsible for the fatal meningitis. Far advanced pulmonary tuberculosis apparently has nothing to do with the development of tuberculous meningitis, although all such patients have had primary foci laid down in various parts of the body before their pulmonary disease began and some have such foci in the brain. If these foci rupture into the ventricles or subarachnoid space, the patients will die of meningitis in the same manner as those who have no chronic pulmonary disease. Among adults who have chronic pulmonary tuberculosis, the incidence of tuberculous meningitis may be as high as 3 or 4 per cent. It is probable that a number of persons whose deaths have been accredited to tuberculous meningitis in reality had generalized military tuberculosis, with the chief symptoms referable to the central nervous system.

Obviously, there is a much larger number of persons who have tuberculous primary complexes in their bodies than the number who have also developed chronic pulmonary disease. Therefore the potentialities of both tuberculous meningitis and military disease from the standpoint of the total number of cases are greater among those in the general population who do not have clinical pulmonary tuberculosis than among those who have it.

DESENSITIZATION IN HAY FEVER

To the Editor—I am treating some hay fever patients by attempting to desensitize them. 1 In what percentage of cases can one reasonably expect to get practically full relief very good results and fair results? 2 Does the continuous method of desensitization give better results than the pre-seasonal method for the strict ragweed type? 3 Is there any relation between the degree of sensitivity and the results that may be expected? 4 Are the results obtained better if the patient has had it for only one or two years than if he has had it several years? 5 If relief is partial the first year is there apt to be further improvement after additional years? 6 Is it true that in a certain percentage of cases after four or five years the relief is complete? 7 Is there any danger in daily doses of atropine from $\frac{1}{150}$ to $\frac{1}{400}$ grain (from 0.4 to 0.3 mg.) given throughout the season? 8 Is there any tendency for ephedrine if given each season over a period of years to produce any permanent change in blood pressure? 9 What is the safest method in obtaining a palliative relief in a patient who also has hypertension?

R. C. CONNBEARE M.D. Benton Harbor Mich.

ANSWER—1 It is possible to obtain practically full relief in 40 per cent, good results in 30 per cent and fair results in about 15 per cent. It must be realized, however, that these percentages will vary depending on the type of hay fever with which one is dealing and also in the nature of the community wherein the patient resides. For example, grass sensitive patients as a rule give much better results with specific therapy than ragweed sensitive patients. And the percentage of good results in Richmond, Va., will be much greater than in a group treated in the same way in Kansas City. This is due to the fact that the patients in localities such as the latter are exposed to a greater concentration of pollen and therefore are more difficult to desensitize.

2 If one should compare equal series treated by the two methods one would find a larger average of good results among those treated continuously. However, it does happen in occasional patients that pre-seasonal treatment yields better results than perennial treatment for some unknown reason. Furthermore, it must be kept in mind that an important disadvantage of continuous treatment is the fact that the patient often tires of the treatment and may therefore discontinue treatment more quickly than if he is on the pre-seasonal plan.

3 The intensity of the skin reaction has no definite relation to the degree of clinical sensitivity. If the patient's clinical symptoms are mild, the results of treatment will be better, regardless of the intensity of the skin reaction than in a patient whose symptoms are severe. However, of two patients with

the same severity of symptoms, the one with the milder skin reaction will not do as well as the one with the stronger reaction unless he receives a higher maximum dose.

4 Provided no additional sensitization has occurred, and provided no complicating disorder has occurred (such as infection or polyposis), the duration of the symptoms has practically no bearing on the results of treatment.

5 In many cases additional years of treatment improve the partial results of the first year, chiefly because a greater degree of desensitization is possible by continued treatment.

6 A few patients obtain relief that tends to persist. Some have no recurrence of symptoms after many years, while others have recurrences after two or three years.

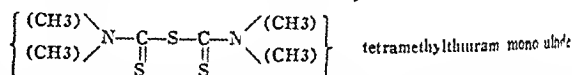

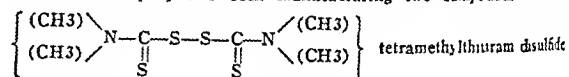

7 In the majority of cases there is no danger to life (unless the patient has an idiosyncrasy for the drug) but there is a possibility of accumulation of the drug within the body with the production of unpleasant side effects and even mild poisoning symptoms. In the experience of some allergists, atropine has not been of any great use in the treatment of hay fever.

8 There is but little danger of producing hypertension from the use of ephedrine given during the season over a period of years.

9 In the majority of patients with hypertension, small doses of ephedrine have little effect on blood pressure. However, in questionable cases, one may use ephedrine locally in the form of sprays or jellies.

EFFECTS OF ALCOHOL ON WORKERS WITH CARBON DISULFIDE

To the Editor—I am a plant physician in a chemical company where among other things rubber accelerators are made. For a number of years the company has been manufacturing two compounds known as

The laborers working with these chemicals especially the ones who grind the finished products find that they cannot drink alcohol in any form. Even beer will cause a flushing of the face and hands with rapid pulse and some of the men describe palpitations and a terrible fulness in the face eyes and head. After a glass of beer (6 ounces) the blood pressure falls about 10 points the pulse is slightly accelerated and skin becomes flushed in the face and wrists. In fifteen minutes the blood pressure falls another 10 points the heart is more rapid and the patient complains of fulness in the head. There doesn't seem to be any other effect of the chemical men have worked here for years without any complaint other than their inability to drink. They have become involuntary total abstainers. I wonder if there is any other way to test the toxicity. We have used a patch test on mice and fed it to mice without harm. If the chemical compound is not harmful to man one wonders whether or has discovered the cure for alcoholism. I would appreciate knowing your reaction on that point.

E. E. WILLIAMS M.D. Naugatuck Conn.

ANSWER—As long ago as 1910, Haas and Heim addressing the International Congress on Industrial Hygiene in Brussels pointed out the disturbing effects of alcohol on workers manipulating carbon disulfide. In the present instance the alcohol may be regarded as a provocative agent, demonstrating the actuality of chemical sulfide poisoning, minor in degree at the present time but possibly constituting much more of a threat to the well being of exposed workers than implied in the query. Each of these accelerators is best known as injurious because of skin irritating properties. Public Health Bulletin 215 of the United States Treasury Department 1934, prepared by Schwartz points to these substances as sources of skin diseases chiefly following sensitization. A similar experience was encountered by O. Borre and Putnam as reported in *THE JOURNAL* Sept. 17, 1933, page 972. Little is known about the systemic action of these complex sulfides. Such as is known reveals a similarity between their action and that of carbon disulfide. Reference should be made to Hamilton's compilation of material on the toxicity of this substance. One paragraph is quoted for the purposes of emphasis but if the toxicity of these sulfide accelerators ever approaches that of carbon disulfide the situation must be reckoned as more than of passing importance.

Recent literature does not yield such extreme cases the usual form now encountered being either a rapidly developing anisotropy or a polyneuritis with more or less paralysis. Laudenheimer collected the histories of no less than fifty cases of early carbon disulfide insanity which were treated in Flechsig's clinic in Leipzig. The early symptoms in these cases consisted usually of frontal headache, dizziness increasing weariness and loss of strength transient excitement and slight delirium very like alcoholic intoxication. Later deep depression came on and

if the exposure continued, an increasing indifference, apathy or melancholy, and always a weakened memory developed. Drowsiness and stupidity would then sometimes pass suddenly into acute mania, or into melancholia with delusions of persecution. These might terminate in recovery or end in incurable dementia."

TREATMENT OF SYPHILIS AND LICENSE TO DRIVE MOTOR CAR

To the Editor—I should like to get your opinion regarding a patient under my supervision for the treatment of syphilis. It was contracted in March 1929. At that time he received a total of twenty injections of a bismuth compound four injections of mercury and fifty tablets of red mercuric iodide. I saw him first in November 1936 because of a severe convulsion. At that time the Hinton Wassermann and Kahn tests were negative. The spinal fluid was normal. An encephalogram and a ven triculogram showed no evidence of a brain tumor. A roentgenogram of the heart and lungs showed a definite increase in the width of the aorta. The electrocardiogram was normal. A diagnosis of cardiovascular and vascular neurosyphilis was made. He has had twelve weekly injections of quinine bismuth iodide 6 grains (0.4 Gm.) accompanied by potassium iodide 20 drops three times daily. The last three weekly treatments have each consisted of 0.3 Gm. of neoparsphenamine. Since the original visit he has had only one convulsion with which he lost consciousness for a few minutes and recovered spontaneously without any after effect. Since January 11 he has had only one mild attack. At that time he did not fall down. He has had a few dizzy spells which were not serious. Since having the neoparsphenamine he has shown rapid improvement physically and seems to be doing as well as can be expected. During the past week he received notice from the state registry of motor vehicles that his license to drive had been suspended. This suspension was done on the advice of the physician who called to see him at the time of the mild convulsion. During the past three and one-half months he has hired some one to drive his car and has made arrangements to continue to do so until May 1 at least. In your opinion how long should one wait with the present plan of treatment before assuring him and the registrar of motor vehicles that he will be in physical condition to drive his own car?

M D Massachusetts

ANSWER.—Since the diagnosis of syphilis is not adequately confirmed, it would be advisable to consider also other causes of fainting, such as hypoglycemia and carotid sinus syncope (see Ferris, Capps and Weiss *Medicine* 14 377 [Dec.] 1935). Assuming that the patient has syphilis and that he continues his treatment, it would be reasonable to suppose that driving a car would not present exceptional hazards after he had been symptom free for a year.

BASLE NOMENCLATURE IN ANATOMY

To the Editor—Will you please send me any literature that you can on the subject of the Basle nomenclature in anatomy? What I especially want to learn is the various advantages which this terminology has proved itself to have over the older set of names. I should also however like to know the date when and the auspices under which the Basle terminology was adopted. If you can also send me something on the assistance which the nomenclature of Linnaeus has afforded to botanists and zoologists I should appreciate the kindness fully.

T H SHASTED M D Duluth Minn

ANSWER.—The BNA (Basle nomina anatomica) is the product of the Commission on Nomenclature appointed by the Anatomical Society in 1889. Its report (the BNA) was accepted in 1895 at a meeting in Basle Switzerland.

This society was international, in 1895 it had 145 German members and 129 members from other nations. The chairman of the commission was Prof W Krause of Berlin, the members included Prof G D Thane of London, and representatives of several other countries were invited to join it. They were among the ablest anatomists of that time.

The need for it appeared in the multiplication of terms. More than 30,000 were in the literature for 4,500 structures. Wilder, Gould and Gage in America, Henle in Germany and the anatomical societies of Germany, Britain and America had urged the necessity of simplification.

The commission served without pay. The cost of correspondence and mimeographing was about \$3,000, it was defrayed by scientific academies of Germany and Austria-Hungary and by the Anatomical Society.

The plan included only names of descriptive gross human anatomical structures. Personal names were omitted except as some few had become universally adopted and firmly established as to make their omission impossible—these were added in brackets. The governing principles were as follows:

1. Each part shall have only one name.
2. It shall be in Latin philologically correct. (Most names were in Latin form anyway and Latin is the only international language.)
3. It shall be short and simple.
4. It need not be descriptive or speculative.
5. Related terms shall be similar.

6. Adjectives shall in general be arranged as opposites, as major-minor, superficialis-profundus.

More minute terms used in the medical specialties were omitted.

The work was admirably done. More than five sixths of names previously used locally were abandoned—they were not necessary. The arrangement of terms indicated the normal structure—branches of vessels, nerves and others. The use of these names in the atlases of Spalteholz, Toldt and Sobotta and in the textbooks of all countries led to its adoption almost universally, to the great advantage of medical sciences and of medical students.

The International Association of Anatomists, established later, has continued the revision. It has now a Commission on Nomenclature, including several American members, Professor Jackson of Minnesota is chairman of the American section. The commission has suggested a few changes and is now considering others.

Linnaeus (Carl von Linne, 1707-1778) introduced method and classification into botanic nomenclature. His classification was based on pistils and stamens and his arrangement included genera and species. His names were in Latin form. Previous classifications were based on medical use (Brunfels 1530), on fruits (Caesalpinus 1583), on external appearance (Gerard 1597), on flowers (Ray 1682) and on the corolla (Tournefort 1760).

Linne's system had a better basis than its predecessors, because pistils and stamens are more important organs.

Jussieu and Brown made classifications later which including all parts and all the life history of plants, were better than Linne's.

ASPERMIA AND DELAYED OR ABSENT ORGASM

To the Editor—A man aged 33, single, 5 feet 8 inches (173 cm) tall and weighing 175 pounds (79 Kg) is well developed and nourished, has dark hair and brown eyes, is a saw mill worker of good average intellect and gets along well with his employer and fellow workmen. He has the average number of both male and female friends. He sleeps and eats well and enjoys his work. On examination the Kahn test is negative and the hemoglobin, red cells and white cells are normal. The blood pressure is 127 systolic, 80 diastolic and the urine is normal. There is normal distribution of the hair of the body. The penis is of average size and the testes are normal in size and sensation. The prostate and urethra are normal. There is no family history of insanity or nervous breakdowns. At the age of 18 he had his first sexual intercourse and at 23 he had gonorrhea which cleared up in about five months under medical treatment. From 23 years of age to 31 he had intercourse with various women but usually not oftener than once a month. From 31 to 32 he had intercourse twice and not at all for the past year. These are his own words. Doctor, I think there is something the matter with me. I want to get married but I am afraid to because I will make a nervous wreck out of my wife. I am afraid I would send her crazy. Why? I asked. Because it takes me so long to come and the girl is all nervous and played out. I have gathered these points from the history. From his first intercourse till he had gonorrhea he had noticed no inability to have and hold an erection but he did notice that the time required to work up to an orgasm and ejaculate was longer than normal. As he has grown older there is no inability to have an erection and hold it but there are times when he has no ejaculation and no sense of satisfaction. Intercourse with a prostitute once lasted so long that she refused him further. Another time he had intercourse once a week for three months and was again refused for the same reason. Lately intercourse has been so unsatisfactory that he has not indulged for a year. Now the question of marriage comes up and I am anxious to find a way of helping him. Could you throw any light on the condition?

M D British Columbia

ANSWER.—This is a rather unusual condition known as aspermia. In the typical case, the patient has normal desire and normal erection but, try as hard as he may, he cannot have an ejaculation during coitus. Some of these patients can masturbate with ejaculation, some have wet dreams, and in most of them fluid containing live spermatozoa can be expressed by massaging the prostate and stripping the seminal vesicles. During coitus however, which may be kept up indefinitely, no ejaculation occurs. In some cases, during coitus, the fluid regurgitates into the bladder instead of coming out of the urethra and an examination of the urine after coitus will show the presence of semen.

The condition has sometimes been acquired by the patient holding back his ejaculation during spooning and even during coitus, thus deranging the entire valvular and nervous mechanism. Cases have been reported in which an examination of the prostatic urethra with the urethroscope showed the presence of bands preventing the proper dilatation of the urethra during coitus. In others there is a nervous inhibition during coitus, having the same result.

As regards treatment, the urethra should be examined with the urethroscope and any abnormality found should be corrected. In some instances the ingestion of intoxicants or sedatives will remove the psychic inhibition and effect a cure. All

unnatural and ungratified methods of coitus as well as ungratified sexual excitement (such as spooning) must be forbidden. The condition is difficult and in some cases almost impossible to cure. It is interesting in this connection to note that the operation of presacral neurectomy performed to relieve bladder pain which cannot be relieved by any other method will cause aspermia.

SKIN SENSITIVITY AND HAY FEVER

To the Editor—A medical student aged 26 began sneezing the last week in August and his attacks have continued since. Skin tests revealed sensitivity to timothy, June grass, orchard grass and red top. There was no reaction to ragweed. The patient has not left New York. Please explain the discrepancy between the skin tests and the occurrence time of the symptoms.

MD New York

ANSWER—The sneezing coming on the last week in August and continuing through the ragweed season would certainly suggest hypersensitivity to ragweed. The method of skin testing was not mentioned in the query and it may be that the patient's skin is not especially sensitive. If the first tests were done by the scratch method and were negative to ragweed, intracutaneous tests to ragweed should then be tried beginning with 1:1,000 dilutions and if negative followed by 1:100. If these two also are negative the conjunctival method should be tried. This consists in the application by means of a toothpick of a small amount of raw ragweed pollen to the lower eyelid. A positive reaction is indicated by tears and conjunctivitis, which, if excessive, can easily be relieved by one or two drops of 1:1,000 epinephrine solution. If the patient gives negative reactions to ragweed by all three methods, the scratch, intradermal and conjunctival, almost certainly he is not sensitive to ragweed. In such an event the physician should look for other causes of sensitivity besides ragweed and complete skin tests should be done for foods, molds, animal danders and such miscellaneous substances as house dust, cottonseed and orris root.

Mention is made that positive reactions were obtained for four grasses: timothy, June grass, orchard grass and red top. This does not necessarily indicate that the patient is clinically sensitive to grass pollen but means that the patient is a potential grass hay fever sufferer. An overdose of grass pollen such as might occur from spending June and July among weeds might well precipitate a typical grass hay fever, which might then recur year after year.

TESTS FOR ALBUMIN IN URINE

To the Editor—I have used Heller's test for the detection of albumin in the urine. Lately however I have had a patient who gives a reaction that is not typical. The urine is water clear and varies in specific gravity from a low of 1.004 to a high of 1.018. He is 42 years old. There are no casts in the centrifugated specimen. The acid is put carefully into a dry tube and the urine is run down the side of the tube. There is no immediate reaction at the point of contact. About three to five minutes after the test is made in about half of the specimens a delicate ring shows up just above the point of contact. It is always opaque but sometimes it is of a delicate purple. Is this an ordinary reaction for a trace of albumin or is it something else? It is a matter of insurance for a personal friend and I am puzzled as to whether it is to be counted as a positive or negative albumin test.

JOSEPH R. LATHAM MD New Bern N. C.

ANSWER—The Heller test is excellent for routine work but must be checked by more delicate methods when there is any doubt concerning its accuracy. There are several substances which form rings with nitric acid which are not serum albumin.

Nucleo albumin forms a ring about 1 cm. above the point of junction. Epithelial cells, white cells and red blood cells are usually the cause of the nucleo-albumin.

Urea forms a crystalline white ring at or near the point of junction.

Bence-Jones protein also forms a ring at the junction and must be differentiated by the heat test.

Colored rings at the junction are frequent in highly concentrated urines with nitrogenous waste products.

There are several points which speak against this patient having albumin: (1) delay in the appearance of the ring; (2) the appearance of the ring above the point of contact; and (3) the purple coloration of the ring. In the absence of casts, blood and white cells in the urine, and a specific gravity which has such a wide range, pathologic albuminuria would seem to be unlikely. Orthostatic albuminuria should be considered and samples of urine after exercise and after rest should be tested. Tests for albumin by the heat acetic acid and either the sulfosalicylic acid or the trichloroacetic acid methods should also be employed. Either of these three methods is more delicate than is the Heller test. A kidney function test should also be done.

ALCOHOLIC BEVERAGES ON BREATH

To the Editor—How much whisky, brandy or gin can be ingested without becoming detectable on the breath at a distance of one foot of the face?

EMILIO L. HERBERT MD Brooklyn

ANSWER—This question is difficult to answer because of numerous unknown factors, such as the time interval between drinking and sniffing, cooperation on the part of the exhaler, consumption of food, particularly garlic and onions, halitosis from other sources, the use of mouth washes, and the acuity of the sense of smell of the investigator. Since mere gargling with alcoholic beverages may have a large sphere of influence it is evident that there is no quantitative relationship between amount consumed and fragrance.

PERCENTAGE OF LOSS OF VISION

To the Editor—I have a patient who has an industrial loss of central vision. He has complete loss of central vision. The visual acuity for distance is only 20/200. Naturally there is no binocular vision present. What would your opinion be with regard to the percentage of loss? Would it be 75 per cent or would it be considered only for function, as reported in the 'Estimated Compensation for Eye Injuries'?

W. R. HICKMAN MD Logansport Ind.

ANSWER—According to the compensation table adopted by the American Medical Association in 1925, further information is needed before an estimation of percentage of loss can be made in this case. Central visual acuity of 20/200 for distance represents a percentage loss of 80 per cent, but that applies only to one function. There must be taken into account the central visual acuity for near, the field of vision, and the question of diplopia, not to mention the visual acuity for near and for distance of the uninjured eye. Furthermore, it must be stated whether the vision obtained is with the best possible correcting glass.

NAUSEA OF PREGNANCY

To the Editor—I would greatly appreciate a statement on the latest theory concerning nausea of pregnancy. Would the fact that cholesterol is formed in diminishing amounts in the blood of pregnant women have any bearing on the production of nausea during pregnancy? If this is so would the administration of a product consisting essentially of glycocholic tetracetate, fel bovis and cerium isovalerianate correct this condition?

JOSEPH MANDELBERG MD Brooklyn

ANSWER—There is no satisfactory explanation of the nausea that occurs during pregnancy but undoubtedly the psyche plays an important part. Only about 50 per cent of pregnant women have this symptom. Contrary to the statement made in the query, cholesterol is not decreased during pregnancy but definitely increased. Slemons and Stander believe that the striking increase in cholesterol during gestation is at least in part a preliminary provision for lactation. It is impossible to say whether the substances mentioned will overcome the nausea associated with pregnancy but if they prove to be successful a large part if not all of this benefit will be due to the psychic effect of the administration of medicine.

TETANUS ANTITOXIN NOT A SUBSTITUTE FOR DIPHTHERIA ANTITOXIN

To the Editor—If one had a bad case of diphtheria and had tetanus antitoxin would one be justified in giving tetanus antitoxin for the diphtheria? I gave a child tetanus antitoxin by mistake for diphtheria and the case cleared up as nicely as any case of diphtheria I ever treated with diphtheria antitoxin. Is it not the foreign protein in the antitoxin that does the work and not the particular germ used in its manufacture? Please omit name.

MD Tennessee

ANSWER—The specific curative action of diphtheria antitoxin is due to the antitoxin that neutralizes the diphtheria toxin in the patient. A physician would not be justified in giving tetanus antitoxin in place of diphtheria antitoxin in patients suffering from diphtheria.

TRAUMA IN RELATION TO DIABETES

To the Editor—I have a patient who is afflicted with diabetes. He claims that this diabetes did not exist prior to the time he received an injury to the sixth cervical vertebra and I can see no connection between the diabetes and the injury to this vertebra. Do you have a treatise on this subject?

M. V. WICKER MD Wayland Ky

ANSWER—A volume issued March 17 by Lea & Febiger, South Washington Square, Philadelphia, bears the title 'Trauma in Relation to Disease'. One of the articles in it is entitled 'Trauma in Relation to Diabetes' and it is written by Elmer P. Joslin MD.

Book Notices

Neurology By Roy R Grinker M D Chairman the Department of Neuropsychiatry of the Michael Reese Hospital Chicago Second edition Cloth Price \$8.50 Pp 999 with 406 illustrations Springfield Illinois & Baltimore Charles C Thomas 1937

Three years has elapsed since the publication of the first edition of this competent work on neurology. Modern neurology advances so rapidly that extensive revisions have been required in this time. For instance, much has been learned concerning the vegetative nervous system and the functions of the central cortical centers. There have been extensive advances in the knowledge of the cerebral cortex. During the past three years there have been serious epidemics of encephalitis and in St. Louis particularly there have been two extensive epidemics of a special type not seen elsewhere and, therefore, especially classified as of the St. Louis type. Electroencephalography has been introduced as a method of study, highly technical in character, and its use has been applied to various neurologic disturbances. Moreover, new treatments have been developed for myasthenia gravis and myotonia congenita, involving drugs not previously applied in these conditions. In fact, there is some question as to the exact value of some of these new preparations. Nevertheless, enough has already been learned to indicate that prostigmin and atropine do produce definite effects in myasthenia gravis. In myotonia quinine has been much used and here also the subject is still under investigation. As in previous years there have been new treatments for migraine but there is still an intricate classification and an outline of treatment based on extensive studies. It is observed that the author speaks of the use of cannabis in increasing doses—an old form of treatment among neurologists but one that is gradually passing into desuetude. A recent governmental action relating to the control of this product may result in its elimination from the list of useful preparations.

This textbook of neurology is remarkable in its completeness. The author has apparently made a constant and extensive survey of available medical literature and he has attempted to integrate the new information with well established data so that there is hardly a subject on which the user of the book will not find some valuable material. Again the publisher is to be commended for the quality of the publication. The book is printed in clear type on fine stock and all the pictures are artistically developed, well selected and instructive. A comprehensive index completes the work.

Morphologische Pathologie Eine Darstellung morphologischer Grundlagen der allgemeinen und speziellen Pathologie Von Prof. Dr. Werner Hueck Direktor des Pathologischen Instituts der Universität Leipzig Paper Price 52 marks Pp 818 with 811 illustrations Leipzig Georg Thieme 1937

The material presented in this book corresponds to that encountered in a textbook of general and systemic pathology, though the author deliberately avoids so describing it. He wishes to reserve for himself the right to decide which of his subjects are the more important, which should be discussed more fully, and which may be omitted. Therefore he chooses "Morphologic Pathology" as a title, implying a treatise on morphologic principles of general and systemic pathology, not necessarily complete. Yet he follows the old principle, and in going over the book one is immediately aware of the fact that, as in similar textbooks the subject is divided into two parts, general pathology—termed "general morphologic pathology"—and systemic pathology—termed "applied morphologic pathology." However, in the chapter dealing with diseases of the respiratory tract, pneumonia, tuberculosis emphysema and car-

cinoma are discussed, whereas diseases of the trachea and bronchi, infarcts and syphilis of the lung are not treated. Some of these diseases are discussed in other relevant chapters or are contained in the part dealing with general pathology. Diseases of the nervous system are not considered in a chapter. There is, however, a chapter on tumors of the nervous system and a few lines are devoted to syphilis. The development of the heart and anomalies of the heart, extensively discussed, at least more exhaustively than in textbooks on pathology. Such a selection of subject matter is of course intentional, since, as the author states, special subjects not being adequately discussed in this volume may be found in much greater detail in various monographs. The selection of special subjects and the more detailed treatment of some of the chapters will be welcome to those who already have a working knowledge of pathology. However, the medical student who wants to find in an individual chapter a treatment of all the various diseases encountered in a particular organ or system of organs may at times be disappointed. It thus provides a volume of information which for the more experienced will be helpful but for the beginner may be confusing. The book is easily comprehensible and is simply written. Long, complicated sentences are avoided. It is thorough and modern, discusses the most recent theories impartially, and is thus neither dogmatic nor too conservative. The reader is impressed with the author's profound knowledge, which is evident in every chapter. Most of the illustrations are reproductions of drawings, which are excellent. Special features are schematic drawings, which illustrate and clarify the development of various cell groups. The book is well assembled, clearly printed and has an adequate index but no bibliography.

Les maladies du pharynx Clinique et thérapeutique Par C. Chassagnon professeur de clinique oto-rhino-laryngologique à la Faculté de médecine de Strasbourg. Avec la collaboration de MM. Reverchon professeur de clinique oto-rhino-laryngologique à la Faculté libre de médecine de Liège Trufferi oto-rhino-laryngologiste de l'Hôpital Bon Secours (Paris) et le concours de Ch. Wild chef de clinique oto-rhino-laryngologique à la Faculté de médecine de Strasbourg. Cloth Price 200 francs Pp 216 with 216 illustrations Paris Masson & Cie 1936

With the exception of the textbooks by Heyman, Katz, Blumenfeld and Denker-Kahler, the present volume is the first to deal exclusively and extensively with the diseases of the pharynx. The book embraces a wide variety of topics many of which are usually given scant attention in the average textbook. Here, however, the laryngologist will find them thoroughly and adequately treated in a fashion that will reflect the best of recent literature. It is gratifying to find such subjects as parapharyngeal infections, the prophylaxis and treatment of hemorrhage, paresthesias of the pharynx, sepsis of tonsillar origin, malignant tumors and focal infection given the space they merit. Our knowledge of these subjects has in recent years been widened through many valuable contributions to the literature, with which most laryngologists are familiar. It is therefore of immense value to the specialist to be able to find them all gathered into one volume. Naturally the French point of view on some of these topics does not coincide with that which is held in this country or in England or Germany. However, such differences as may be noted are not of major importance. For instance the elaborate classification of malignant tumors seems too intricate in view of the tendency in this country toward simplification. The author's nomenclature is also not wholly in conformity with custom here. It is strange to find no mention of lympho-epithelioma or transitional cell carcinoma, although the illustrations of "epithelioma cylindriques" and "sarco-endothelioma reticulare" seem to denote tumors that would be designated by these terms. However, the story of these tumors from histopathology and diagnosis to treatment is well told and leaves nothing to be desired. Carcinoma of the nasopharynx is particularly well handled. The illustrations showing the anatomic relationships of the tumors most frequently involved in the spread of the disease are presented in such a manner as to clarify the symptoms, which in these cases is so diverse. Most of the illustrations throughout the book are original and serve their purpose admirably. Naturally in a book of this size coming from a foreign clinic one finds many things with which one must take issue. The old Mikulicz tonsil clamp is obsolete in this country and suturing the pillars for the control of tonsillar

tonsil bleeding is also rarely used, yet both procedures are advocated and illustrated in this book. On the other hand the author's views on electrocoagulation of the tonsils coincide almost exactly with those most recently expressed in symposiums before our national societies. There is one suggestion that might be offered to the author of this excellent work as well as to all foreign writers, which, if heeded, would do much to increase their popularity here, namely, that they extend their bibliographies to include more English and American references. Most American authors, on the contrary, are particular about citing all noteworthy foreign literature.

Sex and Personality Studies in Masculinity and Femininity By Lewis M. Terman and Catharine Cox Miles. Assisted by Jack W. Dunlap et al. Cloth. Price \$4.50. Pp. 600 with 16 illustrations. New York & London: McGraw-Hill Book Company Inc. 1936.

There is probably no name with which the scientific psychological world is more familiar than that of Lewis M. Terman, who standardized the modern Binet test, which is used in the United States and which has now been applied to many millions of people. He is known to the cognoscenti for his excellent work concerning the differences in the thinking processes of the superior child and the near-genius. Such monumental works are only a sampling of the excellent contributions which the senior author of the present volume has made to the science of psychology. The junior author, Catharine Cox Miles, has already published an excellent study of the social psychology of sex, so that there are probably no two people who are, together, better equipped to study the problem predicated in this book. The present volume is an outgrowth of Terman's earlier studies of genius and here is presented a battery of word association tests, tests of emotional and ethical attitudes and other tests which he has devised and which seem to set off the masculine type of personality from the feminine. There is considerable detail in this book to establish the standardization of each of the subtests in the whole battery, and in interpreting the significance of the test as a whole in relation to such traits as age, domesticity and work adjustment. Particularly there is correlated the masculine and feminine test score with physical measurements, personality and achievement, age, education and intelligence, occupation and domestic milieu. The authors include also some chapters discussing homosexual individuals, and there are also case studies devoted to this type as well as to the masculine and feminine types of delinquent girls. There are seven appendices, consisting mostly of the tests themselves, and various types of norms and conversion tables, which make the work a well rounded scientific piece of reporting. No psychiatrist, medical psychologist or physician who is interested in sexual pathology can afford to be unacquainted with it. The tests will undoubtedly be modified and improved as time goes on. But even at this stage of development these tests and their results are a distinct contribution and well worthy of perusal.

Practical Psychology for Nurses and Other Workers in Mental Hospitals By W. J. T. Kimber, LRCP, DPM, Medical Superintendent Hill End Hospital for Mental and Nervous Disorders, St. Albans. Cloth. Price \$1.25. Pp. 103. New York & London: Oxford University Press. 1937.

The opinion has been expressed even by British psychiatrists that psychiatry in the United States offers leadership to that on the European continent and to that practiced in Great Britain. Whether this opinion is actually true or not, the present volume leads toward that conclusion. It is a tiny volume within which the author attempts to explain the workings of the Freudian psychology, Adlerian psychology and general technique in the psychological handling of patients. He devotes the last fourth of the book to brief discussions of mental disease entities, which are so brief that they neither give a picture of the disorders nor give the nurse a practical idea of what she is up against in handling such patients. What, perhaps, this book should be called is a very elementary psychopathology rather than a psychology. The psychoneuroses and feeble-mindedness are given only a few paragraphs. The idea of deep therapy is scarcely touched on. One wonders what the real purpose is. Even the discussions of Freudian and Adlerian mechanisms are inaccurate although one must admit that they follow the general concepts of the adherents to these special forms of psychological mechanics. The directions given to the nurse in two chapters on how to draw the patient back into

reality are scarcely more than a rather detailed discussion of the everyday means used in hospitals of interesting the patient in his surroundings and in activities which might be made available for him. Occupational therapy is touched on but only briefly, and the involved, carefully developed occupational therapy techniques in use in this country do not seem to be within Dr. Kimber's ken. In a like fashion one finds nothing about systematic recreational proceedings, so often carried out by nurses in America, and real nursing, such as the administration of bath, packs, hospital management and dietetics, all of which have a definite psychological plan if properly understood, are given no consideration. Kimber devotes a chapter to the place of the social worker, but apparently he employs social workers only as home visitors. He probably would be surprised to know how in the United States the social worker, who so seldom is a nurse, handles the case under the direction of a psychiatrist from the point of taking the initial history, making the home investigation and actually carrying out therapy in the home and with the patient. It can be seen, then, that for mental hospital nurses in this country this book can have but little point.

Milk and Nutrition. New Experiments Reported to the Milk Nutrition Committee. Part I. The Effect of Commercial Pasteurization on the Nutritive Value of Milk as Determined by Laboratory Experiment. From the National Institute for Research in Dairying (University of Reading) and the Rowett Research Institute, Bucksburn, Aberdeen. Paper. Price 2s. 6d. Pp. 67 with illustrations. Shinfield, Reading: National Institute for Research in Dairying. 1937.

This pamphlet consists of an interesting series of reports made to the English Milk Nutrition Committee on the effect of commercial pasteurization of milk on its nutritive value, as determined by chemical, physical and biologic methods. Physical and chemical means were used to determine the effect of pasteurization with regard to vitamin A and carotene and to vitamin C. In the studies on the nutritional availability of calcium and phosphorus, on the biologic value of milk proteins, on the vitamin B complex, and on the total nutritive value of milk, rats were used in pairs equalized as to litter and sex, and receiving equal amounts of raw or pasteurized milk. Basal diets fed in addition to the milk were also equalized within pairs. The results of the experiments are reported in tables and a statistical appendix is included. It was found that the nutritional availability of calcium and phosphorus and the biologic value and digestibility of the proteins were not affected by pasteurization. In order to prevent a nutritional anemia in the rats fed on milk exclusively, iron, copper and manganese were added to the feedings, and such supplementary diets, with pasteurized milk as the basis, were found not inferior to raw milk thus supplemented. Vitamin A and the provitamin carotene were not affected by the heat treatment, but vitamin B was, probably in the more unstable B₂ fraction. There was a loss of about 20 per cent in vitamin C in the experiments, a loss which the authors declare is not due to the pasteurization factor alone. The extent to which these results can be applied to the problems of human nutrition and the general advisability of the pasteurization of milk for human consumption are to be discussed in a future report pending the results of feeding experiments now being carried on in calves and in children. This report, and those which follow, will be of interest to biochemists, pediatricians, dairymen and students of nutrition.

Interprétation du fonctionnement du système nerveux par la notion de subordination. Subordination et posture. Par Pierre Mollaret, médecin des hôpitaux de Paris. Préface du Professeur J. Lapicque. Paper. Price 60 francs. Pp. 441. Paris: Masson & Cie. 1937.

The work of Lapicque and his collaborators on chronaximetry and allied topics—mainly the influence of the central nervous system on the electrical excitability of peripheral structures (subordination)—is presented by the author with abundant details and enthusiastic conviction. Stress is laid on clinical observations and literature, even when but indirectly related to the subjects under discussion. The bibliography contains almost exclusively French and German publications; authors of other nationalities are mentioned only as quoted by French commentators. Thus, figure 16 is reproduced from an article by Rosenbluth and Morison and this article is not included in the bibliography. Similarly the chapter devoted to the theory of chemical transmission of nerve impulses does not give any references to Cannon, Feldberg or Dale. An utter

disregard of the overwhelming adverse criticism that has recently been published concerning many of Lapique's statements about isochromism, curarization, subordination and "iterative" systems results in an artificially cogent body of knowledge. The book should be useful for anybody interested in the opinions of authors who favor Lapique's ideas concerning the excitability of nerve centers, nerves and muscles, and the corresponding literature, on the other hand, the book is not adequate for the needs of a reader interested in finding out what is the present status of the problem.

The Etiology of Mental Deficiency with Special Reference to its Occurrence in Twins. A Chapter in the Genetic History of Human Intelligence. By Aaron J. Rosanoff M.D. Levi M. Handy M.A. and Isabel Rosanoff Plesset B.A. Psychological Monographs Volume XLVIII No. 4 Whole No. 216. Edited by John F. Dashiell. Paper Price \$2 Pp 137. Princeton N. J. Psychological Review Company 1937.

This is one of several reports concerning the analysis of a collection of 1,014 pairs of twins with some kind of mental disorder in one or both of the twins in each pair. Previously published studies in this series have dealt with the etiology of mongolism and with that of epilepsy. This report deals exclusively with mental deficiency. The arbitrary range for mental deficiency is placed at 79 points I.Q. and lower. In the whole collection of twins there were found to be 366 pairs one or both of whom were mentally deficient. Of these, 126 pairs were diagnosed by the Siemen resemblance method as monozygotic, 101 pairs as same-sexed dizygotic, and 139 pairs were opposited-sex twins and therefore dizygotic. Siemen's concordance-discordance method in a modified form was used in the analysis. The authors conclude that only a little more than half of the cases of mental deficiency are of hereditary origin. The rest of the cases are attributable to a variety of conditions that might be classed as environmental and include damage to germ cells, fetal and intranatal factors, premature birth (which is prevalent among twins), underweight at birth, and perhaps most important of all, cerebral birth trauma. Many of the discordant cases of twins involved complications attributed to birth trauma, such as infantile cerebral palsies, epilepsy and allied conditions. In 43 per cent of all subjects with mental deficiency there were complications involving palsy, epilepsy, psychotic manifestations, child behavior difficulties, juvenile delinquency and adult criminality. Sex was shown to be a conditioning factor in mental deficiency. There was a significant preponderance of deficient males as compared with females. The authors consider that about one fifth of this is due to sex-linked factors and the rest to greater vulnerability of males to birth trauma. The whole study bears the marks of careful scientific method, unbiased analysis of results, and conservatism in conclusions. It well illustrates the great value of twin materials and of the twin method in the study of the heredity-environment problem.

Aids to Pathology. By Harry Campbell M.D. F.R.C.P. and Kenneth Campbell O.B.E. M.B. F.R.C.S. Seventh edition. Cloth Price \$1.50. Pp 263 with 12 illustrations. London. Baillière Tindall & Cox. Baltimore. William Wood & Co. 1936.

Six previous editions have proved the usefulness of this little book, which for its size contains a remarkable amount of information. It is a concise treatise of general and systemic pathology to which the clinical picture has often been added. The style is somewhat dogmatic and thus certain inaccuracies are found, such as the statement that aneurysm leads to hypertrophy of the left ventricle. One unusual feature is the use of classical quotations in describing certain phases of diseases; for instance, the description of syphilis by Shakespeare. It is also interesting to read in such a small volume, in the chapter on coronary arteries, that John Hunter died of coronary thrombosis. The book is written for the use of the student and the practitioner. While the former will gain much information, it may be a little confusing to him because of the abundance of material presented. On the other hand such graphic descriptions as "it may be said that the malignant cells at one time orderly members of the cell community harmoniously cooperating with the other tissues of the body for its welfare as a whole, become rebels and traitorously turning on that will doubtless simplify for the student some of the problems which in larger textbooks are usually set forth in a less imaginative style."

Quelques vérités premières (ou soi disant telles) en urologie. Par le Marlon professeur de clinique urologique à la Faculté de médecine de Paris. Collection publiée sous la direction de MM. L. Ombredanne et F. Flessinger. Paper Price 24 francs. Pp 61. Paris. Masson & Co. 1936.

This brochure is one of a series of compendiums or "precepts" devoted to a specialty in medicine or surgery. Marlon succinctly phrases dogmas which he considers fundamentally important in urology. His desire is to establish a program of examination and treatment that will be valuable in practice, and he realizes that further progress will lead to new precepts and axioms tomorrow. There is little that is new in this brief compend, but it will be of great value to the student and stimulating to the practitioner as a brief review course. A few precepts taken at random will show the terse phraseology: "To think that all renal calculi are accompanied by pain will lead to failure of diagnosis in many renal stones. Many stones manifest themselves only by pyuria, others by hematuria, others by the abrupt onset of anuria, and some are absolutely latent."

In cases of tuberculous epididymitis it always is necessary to thoroughly study the urine to determine whether the urinary tract is also affected. Often renal tuberculosis is present and is latent, and its proper care is of major importance.

Introduction to the Rorschach Method. A Manual of Personality Study. By Samuel J. Beck Ph.D. Head of the Psychology Laboratory Department of Psychiatry. Michael Reese Hospital Chicago. With a preface by F. L. Wells Ph.D. Monograph No. 1 of the American Orthopsychiatric Association. Cloth Pp 278. Menasha Wisconsin. George Banta Publishing Company 1937.

This book is written to aid investigators and clinicians in the use of Rorschach's ink blot "tests" in the study of personality. The writer assumes a familiarity on the part of the reader with the tests. He endeavors to establish a "normative objectively stable standard of procedure" in the use of the ink blots. He presents in detail fifty-nine case records, among which are represented ten different groups of subjects ranging from healthy adults of superior intelligence to neurotic and psychotic groups of cases. The responses of the subjects to the ink blots, the author's scoring of each response and his interpretations of the observations on each subject are given. These case records constitute the first half of the book. The second part deals with the experimental technique in application of the test material, and exact procedure in scoring the responses. There is little question that in the hands of one expert in the method the Rorschach ink blots constitute a useful and penetrating device for a diagnostic approach to personality study. Dr. Beck's book should do much to clarify many uncertainties in the use of the test. His work makes it possible for investigators working with the ink blots to compare their scorings and observations with much greater definiteness and precision than has been possible heretofore. Dr. Beck's work warrants the most careful attention from workers interested in objective methods of studying personality. He has adhered closely to the original principles laid down by Rorschach but has introduced those modifications in scoring indicated by his own considerable experience. As a guide and aid in the use of the method, it will be found to be second only to the original Psychodiagnostik of Rorschach.

Wissenschaftliche Forschungsberichte. Naturwissenschaftliche Reihe. Herausgegeben von Dr. Raphael Ed. Lesezug Frankfurt a. M. Band XLII. Experimentelle Mutationsforschung in der Vererbungslehre. Beeinflussung der Erbanlagen durch Strahlung und andere Faktoren. Von N. W. Timofeeff-Ressovsky. Genet. Abt. des Kaiser Wilhelm Instituts für Hirnforschung. Berlin. Buch. Paper Price 15 marks. Pp 181 with 58 illustrations. Dresden & Leipzig. Theodore Steinkopf 1937.

This is a collection and organization of all the results obtained in the mutation research of the science of genetics in the years 1914 to 1936. In the first chapter the author gives a short but comprehensive review of facts and definitions of the science of genetics. In the second chapter the experiments of the Lamarck school are discussed from the historical point of view and criticized. Chapter III deals with the modes and means of experimental influence of the "erbang" (process of heredity). Chapter IV deals with spontaneous mutation processes. Chapter V is the most important. It deals with the induction of mutation by short wave radiations. Muller's first experiments on *Drosophila* are included. Chapter VI is an analysis of all the mutation producing factors of radiations. It con-

tains ideas on direct and indirect effects of radiations and the influence of secondary factors, it shows the relation between the rate of mutation and the doses of radiations, the rate of mutations and the intensity of radiations, the rate of mutation and wavelength and kind of rays. Chapter VII is an analysis of the mutability produced by radiation. Chapter VIII deals with the production of mutations by temperature and other external factors. Chapter IX shows the nature of the mutation process and the gene structure. The tenth and final chapter gives the practical applications of the results of experimental mutation research. The bibliography will be found most complete and useful to students of this field. The plates and pictures are excellent.

Post Mortem Appearances. By Joan M. Ross, M.D., B.S., M.R.C.S., Morbid Anatomist to Royal Free Hospital, London. With preface by E. H. Kettle, M.D., Professor of Pathology and Bacteriology, Welsh National School of Medicine, Cardiff. Third edition. Cloth. Price \$2.50. Pp. 243. New York & London: Oxford University Press, 1937.

The major portion of the book is a concise review of gross morbid anatomy, while in a few pages the author describes the technique of postmortem examinations in a rather cursory way. A relatively large section is devoted to deaths from other causes than disease. In this section the observations in instances of chemical poisoning are reported. This is helpful even though the larger textbooks frequently do not refer to medicolegal cases of this type. In general the various diseases are discussed by citation of examples. Acute rheumatism, for instance, the author discusses by describing the external appearances of the patient who died from this disease and by enumerating the abnormalities of the cardiovascular system, the respiratory system, and so on. This method has its advantages in that the student becomes familiar with the various diseases through the medium of individual case discussions, but it is difficult for the beginner to follow because a classification of diseases according to systems is not given. The book is well written and will probably be useful to students for the purpose of rapid general review in preparation for examinations.

Die Entwicklung der Lungentuberkulose des Erwachsenen. Dargestellt in schematischen Tafeln und in röntgenologischen Verlaufsserien. Von Dr. Wilhelm Kremer, dirigierender Arzt der Heilstätten Beelitz. Mit einem Geleitwort von Dr. Frischbier, ärztlicher Direktor der Heilstätten Beelitz. 15. Heft Praktische Tuberkulose-Bücherei. Beilhefte des Deutschen Tuberkulose-Blattes. Herausgegeben von Prof. Kurt Klara Schellong, Altdorf. Paper. Price 4 marks. Pp. 37 with 55 illustrations. Leipzig: Georg Thieme, 1936.

Dr. Kremer's monograph is devoted to the evolution of pulmonary tuberculosis in adults. He reviews the work of Ranke in dividing the disease into three stages, the first consisting of the primary infection, the second of generalization and the third of the development of phthisis in certain organs. The illustrations show the various steps in the development of tuberculosis from the appearance of the primary complex to the far advanced stage of the disease.

Health Questions Answered. By W. W. Bauer, B.S., M.D., Director of Bureau of Health and Public Instruction, American Medical Association. Cloth. Price \$2. Pp. 368. Indianapolis & New York: Bobbs-Merrill Company, 1937.

To one engaged in public health education the questions asked by the public on matters pertaining to health are a constant source of interest and amazement. This book contains several hundred such questions. Even if no attempt were made to answer the questions, the book would make interesting reading because it would tell one how the public thinks. The medical profession is very prone to become highbrow, but the public as revealed by these questions is interested in matters much closer home. The second point of interest is the ingenious manner in which these questions on every subject under the sun have been answered. Answering health questions is not an easy project. One is under the difficult assignment of satisfying the person asking the question, himself, and the ideals of scientific medicine. This is not easy when the layman has a poor understanding of the subject and the doctor an inadequate experience in expressing technical facts in clear, simple language. We strongly recommend this book to persons who by virtue of their work are frequently called on to answer the layman's questions.

The Basis of Clinical Neurology. The Anatomy and Physiology of the Nervous System in Their Application to Clinical Neurology. By Samuel Brock, M.D., Associate Professor of Neurology, College of Medicine, New York University. Cloth. Price \$4.75. Pp. 360 with 72 illustrations. Baltimore: William Wood & Company, 1937.

This book is intended to present neuro-anatomy and especially neurophysiology mainly from the standpoint of clinical usefulness. It is divided into twenty-four chapters to include the peripheral nervous system, spinal cord, brain stem, cerebellum, epithalamus, extrapyramidal systems, the brain, the vegetative nervous system, posture and the cerebrospinal fluid. The author has ably described in his introduction changes in the nervous system brought about by evolution. There is considerable information in every chapter. Many questions pertaining to neurologic signs and symptoms are adequately answered. The language used is simple and easy to read. This volume is recommended for students, teachers and clinicians because the author has included much of the recent work published regarding all functions of the cerebrospinal system.

Atelektasen bei kaverneröser Lungentuberkulose. Von Dr. med. Peter Roth, Assistenzarzt, jetzt an der Heilstätte Lindenhof der LVA Sachsen, Chirurgische Klinik, Coswig/Dresden. Nr. 64. Tuberkulose-Bibliothek. Beilhefte zur Zeitschrift für Tuberkulose. Herausgegeben von Dr. Franz Redeker, Oberregierungs- u. Obermedizinalrat, Berlin, und Dr. Karl Diehl, dirigierender Arzt, Sommerfeld. Paper. Price 7.20 marks. Pp. 59 with 40 illustrations. Leipzig: Johann Ambrosius Barth, 1937.

In this volume, attention is called to the fact that atelectasis is an old subject but that our knowledge of it as a complication of tuberculosis is relatively recent. Ten cases are described in considerable detail and illustrations of roentgenograms of the chest are presented. Tomography was employed to study the extent of cavities in the atelectatic lung. An extensive bibliography is included.

El grupo indeterminado de las afecciones malignas de los ganglios linfáticos (linfogranulomatosis atípica). Por el Dr. N. Puente Duany. Paper. Pp. 94 with 47 illustrations. Havana, Cuba: A. Sanchez Veloso, Editor, 1937.

This little monograph contains a clinical and histopathologic study of ten cases of atypical Hodgkin's disease. After a review of the literature on the subject each case is considered in detail, with special emphasis on the clinical features, the blood picture and the histopathology of lymph nodes subjected to biopsy. The author points out many atypical features, both clinically and histologically. The monograph will be of interest particularly to those pathologists who are studying diseases of lymph nodes.

The Business Side of Medical Practice. By Theodore Wiprud, Executive Secretary of the Medical Society of Milwaukee County. Cloth. Price \$2.50. Pp. 177 with 21 illustrations. Philadelphia & London: W. B. Saunders Company, 1937.

This is a compact, readable work that meets a long recognized need in the medical profession. It can be read by any physician in a few hours, and there will be few physicians who will not gain considerable profit from reading it. The discussions of such subjects as office management, necessary financial records, case records and filing and the proper handling of patients' accounts are straightforward and so well illustrated that misunderstanding is difficult. The author does not recommend a complex "system" of bookkeeping or collections such as so often cumber similar books. The discussion of legal matters properly confines itself to warnings as to the character of the knowledge that is needed and the necessity of securing expert advice when more difficult problems appear. The chapters on public speaking and preparation of a manuscript are wisely elementary and confined to essential suggestions. The book will not make accountants, lawyers, writers or orators out of physicians, but it will help them to avoid difficulties in such amateur excursions into these fields as are constantly necessary.

Tomographische Diagnostik der tuberkulösen Kaverne. Von Kurt Creider, 1. Assistent am Röntgeninstitut der Klinik. Nr. 62. Tuberkulose-Bibliothek. Beilhefte zur Zeitschrift für Tuberkulose. Herausgegeben von Dr. Franz Redeker, Oberregierungs- u. Obermedizinalrat, Berlin, und Dr. Karl Diehl, dirigierender Arzt, Sommerfeld. Paper. Price 3.00 marks. Pp. 18 with 24 illustrations. Leipzig: Johann Ambrosius Barth, 1937.

The illustrations illustrate beautifully this special method of making films of the chest, which show more clearly the extent of pulmonary cavities than the usual method.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts Compensability of Sequelae of a Cold—The claimant, Amann, in the course of his employment as a truck driver for a transportation company, was exposed to the rain and to chilling winds because of the lack of glass in the windows of the cab. He contracted a severe cold. Congestion of his throat, chest and lungs associated with an elevated temperature and the coughing up of blood developed. Finally he was forced to go to bed, where he remained for about three weeks. He then attempted to return to work but was so weak and suffered such pains and aches that he went back to bed. Thereafter he was unable to perform manual labor. He claimed that as a result of his illness he tired easily, was unable to work more than a few minutes at a time, that his heart had been affected causing him pain and suffering at intervals, that he had lost weight and was debilitated, and that his lungs had been affected and weakened. The industrial accident board denied him compensation under the workmen's compensation act of Texas, whereupon he brought suit to set aside the board's decision. From a judgment of the trial court denying relief, he appealed to the court of civil appeals of Texas, Fort Worth.

The purpose of the workmen's compensation act, said the court, is to compensate an employee for injury sustained during the course of employment. The injury contemplated is defined by the act as "damage or harm to the physical structure of the body and such diseases or infection as naturally result therefrom." It was not contemplated that the act should cover health insurance. It is a matter of common knowledge that colds, influenza and pneumonia are the result of germs attacking the body and that many such germs appear to be in the very atmosphere surrounding us at all times. Any and every person is exposed to them without being conscious of the fact. Medical science teaches that human beings fall victims of these germs because at the time they are not physically able to withstand the assaults of the germs. If, said the court, the employee in this case is permitted to recover compensation, then every employee who is engaged in labor which tires the body and causes what the layman calls a "run-down condition" can recover compensation by showing that his work weakened him and lowered his resistance and caused him to succumb to the attack of any disease, which he would otherwise have been able to resist. Attempts so to enlarge the purpose of the workmen's compensation act will destroy its usefulness.

Accordingly, the court of civil appeals affirmed the judgment of the trial court upholding the order of the industrial accident board denying compensation.—*Amann v Republic Underwriters (Texas)*, 100 S W (2d) 778.

Workmen's Compensation Acts Municipal Hospital Not an Industrial Enterprise, Compensability of Injury to Orderly—The workmen's compensation act of Maryland provides that if a municipality shall engage in any extra-hazardous work in which workmen are employed for wages the provisions of the act shall be applicable to such employment. The city of Baltimore operated a municipal hospital wherein medical and hospital services were rendered free to the poor of the city and which housed the aged and indigent. Paul A. Trunk was employed as a head orderly in the hospital, subject to the orders of the head nurse and those of the superintendent. While he was engaged in assisting another employee in moving a heavy steel locker, the door of the locker flew open and struck his back below the right shoulder blade and near the spine. Fifteen months later Trunk died from a "malignant lung condition," which, according to the testimony of the medical experts, developed as a consequence of the blow on his back. His wife instituted proceedings to obtain compensation under the workmen's compensation act. The state industrial accident commission disallowed the claim. The superior

court of Baltimore city reversed the order of the commission, and the employer appealed to the Court of Appeals of Maryland.

The city contended that Trunk, being employed as an orderly at a wage of \$1,200 a year, payable in installments every half month, was not a workman for wages within the meaning of the workmen's compensation act. An orderly, said the court, is primarily a male attendant in a hospital who is charged with the maintenance of order, cleanliness, and with the duty of giving menial services and personal attention. If one of the class is placed in a supervisory position with respect to the others of the class, he remains obliged to perform the common services of the class whenever so directed by his employer or whenever an order for any of such services to be discharged would arise because he is said to be other than an orderly. Trunk's position as an orderly, the court said, did not take him out of the operation of the act when his duties were servile and not professional, and, particularly, when his injury was sustained in an accident which happened while he was engaged in manual labor within the ordinary duties of an orderly.

In *Mayor, etc., of Baltimore v Smith*, 168 Md. 438, 177 A. 903, continued the court, it was held that a nurse injured during the course of her employment in a municipally owned and operated charitable hospital was not entitled to compensation because a public charitable hospital is not an industrial enterprise nor is a trained nurse, in the course of her vocational employment, a workman within the contemplation of the act. In the present case, the court said, the charitable hospital, as such, was not an industrial enterprise nor specifically declared to be an extra-hazardous employment by the workmen's compensation act. Consequently, an employee of the hospital, if injured within the scope and course of his employment, would not be entitled to compensation unless his particular work at the hospital was "work of an extra-hazardous nature," and there was no evidence that it was in the present case. The judgment of the superior court for the claimant was therefore reversed.—*Mayor and City Council of Baltimore v Trunk (Md)*, 190 A 736.

Venereal Diseases Liability of Municipality to Prisoner Who Contracts Disease from Fellow Prisoner—Lewis was a prisoner in the jail maintained by the city of Miami. In the present action he alleges that the city failed to segregate a fellow prisoner who had a venereal disease and as a result of this failure he, Lewis, contracted the disease. The trial court sustained the demurrer interposed by the city apparently on the theory that in maintaining and operating the jail the city was performing a governmental function and was not liable for injuries sustained incident to the performance of that function. The plaintiff thereupon appealed to the Supreme Court of Florida.

A Florida statute, said the Supreme Court, makes it unlawful for any person infected with a venereal disease to expose another person to infection and by necessary implication it is unlawful for the legal custodians or keepers of infected persons knowingly to neglect to protect others likewise within their keeping or custody from exposure to such infection. Municipal prisoners are within the custody of the municipality as a public corporation. There was a time when all municipal functions were governmental and therefore municipal corporations were wholly free from responsibility for torts or civil wrongs. This rule of municipal nonliability for torts is now recognized as to all functions whereby the municipality acts simply as an agency of the state for governmental purposes unless a contrary rule is provided by statute. But as to those corporate powers and responsibilities now residing in municipalities that are outside the narrow range of functions heretofore classed by the common law as purely governmental, municipal liability in an action in tort may exist especially where the injury is the result of neglecting a positive duty of inhibition enjoined on the municipality by law. In municipalities of the present day, jails and workhouses are maintained for the detention of persons not only for the offenses that were within the range of municipal action under common law but for a multitude of other offenses under

bition of which is designed to promote the corporate well being of the city more than to advance the performance of its governmental functions. So, in maintaining a jail, a municipality may be said to be maintaining an institution for its corporate as well as its governmental purposes, under a modern conception of municipal corporations as partly business and partly governmental institutions. The liability in the present case, continued the court, depends on whether the city of Miami neglected to carry out the mandatory duty enjoined on it not knowingly to expose persons in its official custody to infection by others known by its authorities in charge to be venereally infected. The court felt constrained to hold that in the present appeal the declaration to which the demurrer was sustained stated a good cause of action for the negligent breach of this statutory duty necessarily resting on municipal corporations. The judgment of the trial court was therefore reversed with directions to overrule the demurrer and to proceed with the case according to law.—*Lewis v City of Miami (Fla.) 173 So 150*

Privileged Communications Hospital Records, Death Certificates, and Autopsy Reports as Privileged—Official hospital records, said the St. Louis court of appeals. Missouri properly identified, and shown to have been kept pursuant to statutory requirements, are admissible in evidence as an exception to the hearsay rule but they are nevertheless subject to an objection on the ground of privilege arising by virtue of the confidential relationship of physician and patient.

A state statute declaring that certificates of death, when properly certified, "shall be prima facie evidence in all courts and places of the facts therein stated" means that the certificate shall be admissible as against an objection based on the ground of hearsay, such a statute does not undertake to make the certificate admissible as against a proper claim of privilege. Obviously, a physician in making out a death certificate is required to give information which he acquired from his patient while attending him in a professional character, information necessary to enable him to prescribe for the patient. The court could see no reason why such a certificate should be any more immune to a claim of privilege than would have been the testimony of the physician who executed it. The question of the admissibility of a certificate of death as against a claim of privilege should be determined, the court said, in the light of the same considerations as govern the question of the admissibility of a hospital record. While it is true that from its nature and the purpose intended to be served by it a certificate of death may be expected to be subject to a greater degree of publicity than a hospital record, the measure of publicity which a particular public record may receive, the court said, does not affect the question of its privileged status when the record is sought to be made use of in a private controversy involving a person in a position to assert the privilege.

With respect to autopsy reports, the court thought that on both reason and the decided weight of authority such reports were not privileged, and especially so where the information was acquired by an autopsy on the body of a person who was not, prior to his death, a patient of the physician who performed the autopsy.—*Kcy v Cosmopolitan Life, Health & Acc Ins Co (Mo.), 102 S W (2d) 797*

Accident Insurance Death from Veronal Poisoning—The supreme court of New York, appellate division held that death resulting from an overdose of veronal (barbital) unintentionally taken was a death occurring as a result of "bodily injuries effected solely through external, violent and accidental means" *Mansbacher v Prudential Ins Co (N Y), 287 N Y S 486 abstr THE JOURNAL Feb 13, 1937, page 585*. On appeal the Court of Appeals of New York, in affirming the judgment of the supreme court, said that the deceased intended to take veronal but did not intend to take a lethal dose nor did he intend to take enough to do him any harm. He desired to get relief from pain, not relief from life. He took too much veronal. It was a mistake, a misstep, an unexpected effect from the use of his prescribed medicine. His death was therefore caused by accidental means.—*Mansbacher v Prudential Ins Co of America (N Y) 7 N E (2d) 18*

The Effect of Jaundice on Chronic Infectious Arthritis and on Primary Fibrositis

DR PHILIP S HENCH, Rochester, Minn. In 1933 before this association I reported a phenomenon experienced by twelve rheumatic patients who had become jaundiced. My present report summarizes further observations on two additional groups of cases (1) studies on thirty-one rheumatic patients who experienced this phenomenon and (2) of equal importance, studies on four patients with atrophic arthritis and on nine patients with other types of articular and neuritic complaints who did not get relief of symptoms coincident with jaundice.

Of the thirty-one patients who experienced the phenomenon, nineteen had atrophic arthritis. Among the arthritic patients the average duration of disease was 55 years. Eight of the nineteen arthritic patients developed intrahepatic jaundice from cinchophen. The average duration of their jaundice was 45 weeks. Remissions in arthritic symptoms lasted from five to forty three weeks (average 135 weeks). Nine of the arthritic patients developed intrahepatic jaundice from other causes than cinchophen. Jaundice lasted an average of 115 weeks, remissions from arthritis lasted from five to thirty-nine weeks (average 175 weeks). Two arthritic patients developed obstructive jaundice (stones) lasting an average of 135 weeks. Symptomatic remissions induced thereby lasted in one case seven weeks, in another, eighty two weeks.

The duration of disease among the nine fibrositic patients was 52 years prior to jaundice. Six developed cinchophen jaundice which lasted an average of 48 weeks. Remissions from symptoms of fibrositis lasted an average of thirty nine weeks (from four weeks to three years and nine months). Two fibrositic patients developed obstructive jaundice from stones. Jaundice lasted an average of three weeks, remissions lasted five weeks in one case, two years in another. One fibrositic patient developed obstructive jaundice from carcinoma of the ampulla of Vater. Jaundice lasted fourteen weeks but the patient was completely relieved of fibrositic symptoms until death forty-four weeks after the onset of jaundice.

The two patients with lumbrosacral and sciatic pain and the one with secondary arthritis of the hips had symptoms for an average of 23 years before the onset of intrahepatic jaundice. The average length of both jaundice and remissions was five weeks.

Observations were made on four patients who had repeated attacks of jaundice. During attacks of severe jaundice they had complete relief of rheumatic symptoms but with attacks of mild jaundice no relief from rheumatic symptoms was noted. Four additional patients with atrophic arthritis who developed mild jaundice (with concentrations of serum bilirubin below 4 mg) noted no relief from arthritic symptoms. The effect of jaundice is apparently quantitative rather than qualitative. The zone of the therapeutic effectiveness seemed to be at or above a level of about 8 to 10 mg of bilirubin per hundred cubic centimeters of serum. The phenomenon appears to be relatively specific for atrophic arthritis and primary fibrositis.

The relief from rheumatic symptoms was noted as follows "with onset of jaundice" sixteen times, on the first day of jaundice three times, second day four times, third day three times and "suddenly realized" toward the end of the first week of jaundice three times. Five patients apparently noted onset of relief from one to fourteen days before they noted their jaundice. Their jaundice of course may have been visible but unnoticed, or they may in fact have had relief during the stage of subclinical jaundice. Complete relief of all rheumatic symptoms was experienced by 100 per cent of the fibrositic and by 63 per cent of the arthritic patients. The rest of the arthritic patients noted marked (grade 3) but not complete relief. A remission, not a "cure," is induced. Remissions have lasted from three weeks to three years and nine months. They averaged (roughly) from two to three times the average duration of the jaundice. Subsequently symptoms returned "as before" in 48 per cent, in much milder form in 39 per cent, of the cases. In a few, symptoms are still absent, two patients have died.

The responsible agent has not yet been identified. It may be a normal hepatic substance (bilirubin, bile salts, other substance), an abnormal hepatic substance such as liver autolysate or extra-hepatic substance. The mechanism whereby it acts has not yet been determined. The therapeutic implications are obvious. An intensive study of the phenomenon may lead to a better understanding of the pathogenesis of these diseases, perhaps even to some superior method of controlling them by giving the patients repeated remissions, from the use of some nontoxic accompaniment of jaundice effective in available concentration. Various methods to reproduce the phenomenon have been used, so far unsuccessfully, bile salts by mouth, synthetic bile salts (decholin) orally and intravenously, the administration of diluted ox bile by proctodysis and of large amounts of human bile by stomach tube (up to 7,650 cc in ten days, 2,600 cc in one day), and transfusions of highly jaundiced blood. To study the phenomenon more effectively, it seemed justifiable to produce a relatively harmless type of 'experimental jaundice'. A discouraged, incapacitated, arthritic patient volunteered to accept such a measure. "Toluyene diamine jaundice" was produced, the first example of experimental jaundice in a human being. Unfortunately the (hemolytic) jaundice induced thereby did not induce remission.

Some more feasible method of study is needed, a method perhaps adaptable to the field of therapy. But when it is obtained it must be regarded not as an end in itself but as a means to an end. "Therapeutic jaundice" is an attractive term, but even if what it implies can be successfully accomplished it should at best be considered a crude, temporary form of treatment. Two conclusions are permitted now. 1 Chronic infectious (atrophic) arthritis and primary fibrositis obviously are not necessarily relentless, uncontrollable diseases for which no really satisfactory and rapid method of control need ever be expected, certain of their pathologic changes may be permanent but their pathologic physiology is much more reversible than supposed, indeed it is dramatically and rapidly reversible. 2 Nature does possess a highly effective (if rarely utilized) method of producing a dramatic remission, involving a phenomenon precipitated more rapidly and more effectively by jaundice than by any other physiologic change or therapeutic method. The next step belongs to us. It behooves us to discover nature's dramatic if accidental antidote.

Experimentally Induced Jaundice (Hyperbilirubinemia)

DRS HARRY E. THOMPSON and BERNARD L. WYATT, Tucson, ARIZ. Bile contains four main components (1) bile pigments, (2) bile salts, (3) lipidol constituents and (4) mucin. It has been generally observed that out of this group bile pigments alone reach relatively higher levels in the circulation in jaundice of the hemolytic type, while both bilirubin and bile salt are increased in jaundice of the obstructive and toxic type. Although the majority of cases in the literature indicate that those jaundices in which the most beneficial effect on arthritis was noted were accompanied by a rise in the serum bilirubin and bile salt, these two substances cannot be considered entirely responsible, since remissions have been observed to follow jaundice (hemolytic) in which the bile salt level presumably was not raised.

The effect of single and repeated intravenous injections of bilirubin at various dosage levels in rabbits has been observed. The results may be briefly summarized as follows. 1 Bilirubin was rapidly excreted following single intravenous injections. 2 Repeated injections of 20 mg per kilogram of bilirubin for ten days produced a chronic bilirubinemia and a retention in the tissue of the pigment. 3 No toxic effects were noted during administration or at autopsy. 4 The single fatal dose of bilirubin was from 175 to 200 mg per kilogram. The observations indicate that the excretion of bilirubin is not even with repeated doses but that the tissue took up sufficient pigment so that a slight bilirubinemia persisted.

Three patients with chronic atrophic arthritis were given a series of repeated injections of bilirubin in 10 to 15 mg per kilogram doses daily. Observations on these patients demonstrated that bilirubin is rapidly but not completely excreted from the blood following repeated injections. These patients developed a slight hyperbilirubinemia and sufficient retention in the tissue to produce an icterus. Little or no symptomatic improvement was noted in this group.

The administration of bile salt alone (sodium dehydrocholate) was tried in ten patients with chronic atrophic arthritis. They were given intravenously 2 Gm of the salt daily for from nine to twelve days. Little or no symptomatic improvement was noted. The animal experiments were repeated, bilirubin being used in 20 mg per kilogram and the sodium salt of dehydrocholate in 40 mg per kilogram doses. Thus bile salt was selected as it is apparently less toxic intravenously than some other bile salts. In addition to the previous observations the functional capacity of the liver (bromsulfalein) was studied. A brief summary of this study is as follows. 1 In single doses the clearance of bilirubin was essentially the same with bile salt as with bilirubin used alone. 2 With repeated administration there appeared a slightly greater pigment retention in the blood and tissues when bile salt was added to the bilirubin. 3 No evidence of toxicity appeared during or after administration or at autopsy. A patient having a chronic nonspecific atrophic arthritis was selected. He was given daily doses of 10 mg per kilogram of bilirubin intravenously for four days, and on the fifth, sixth and seventh days 40 mg per kilogram of sodium dehydrocholate was added to the infusion. After four injections of bilirubin a slight icterus developed but no relief of symptoms was noted, both knees and one ankle remained warm, swollen and painful. However, within eight hours following the fifth infusion (bilirubin and bile salt) definite relief from pain in all involved joints appeared. The swollen joints had diminished slightly in size and he was more icteric. The serum bilirubin twenty-four hours after this infusion was 281 mg per hundred cubic centimeters. The Van den Bergh reaction was indirect. Following the two succeeding injections the joint swelling rapidly diminished and the analgesia has persisted up to the present time (five months). This reversal of symptoms came on so dramatically and suddenly that one named atele notes the similarity between this case and the reported cases of analgesia occurring clinically with jaundice.

The bilirubin and bile salt were then employed in nine other patients with chronic atrophic arthritis. Briefly, the observations are as follows. Of ten patients, three received seven to eight injections, one ten and one eleven daily infusions of bilirubin and bile salt. The first observable icterus in the eyes was noted after the first to fourth injection. This became generalized after from two to eight injections. However, there were varying degrees of intensity noted, as a general rule the icterus became progressively more marked with each succeeding injection. The observable jaundice disappeared in from fourteen to twenty-three days after the last administration. Diminished swelling was noted after from one to nine injections. Analgesia was noted after from one to seven injections and persisted for varying intervals, the shortest period being twelve days. The longest period cannot be determined, as five patients have had no return of pain up to the present time (eleven to twenty months, five and one-half months, two months, one month and one month). Reactions occurred in from one to thirty-five infusions, fifteen reactions appeared in six patients. All general reactions were of short duration and never appeared dangerous.

Since neither bilirubin nor bile salt alone has an analgesic effect, the mechanism of their combined action is somewhat problematic. The first question that presented itself was: Is there a higher and more persistent hyperbilirubinemia when bilirubin and bile salt were used together than when bilirubin was used alone? The observation on the patients and on rabbits indicate that there is a slightly higher and more persistent hyperbilirubinemia when the two are used together than when bilirubin is used alone. However, the differences are not striking and the clinical relief of symptoms has not been sufficiently parallel to the degree of bilirubinemia to allow any conclusions. It was found that the administration of bile salt was without beneficial effect on the symptoms of chronic atrophic arthritis. Bilirubin employed alone similarly did not give any beneficial effects. However, the combination of bilirubin and bile salt had an ameliorating effect on the symptoms of atrophic arthritis. The mechanism of this action is not obvious, but it seems clear from these studies that one can produce an artificial jaundice which apparently duplicates the effects reported by various workers when clinical jaundice intervenes in patients with atrophic arthritis.

DISCUSSION

DR. NATHAN SIDEL, Boston. Since our original report was published in 1934, I have seen four other patients who showed the analgesic effect of jaundice on their arthritic pain. Two of these patients had obstructive jaundice due to carcinoma of the head of the pancreas, the joint condition was osteoarthritis but there was only slight improvement. The other two patients presented rheumatoid arthritis, and with the onset of catarrhal jaundice the joint pain was alleviated. My first experience with bile salt therapy in arthritis was the giving of bile salts by mouth to the first patient in our jaundice series after his jaundice cleared. This occurred in 1933 and whereas the patient previously had to take from eight to ten acetylsalicylic acid tablets daily for relief, he felt better with the bile salts and has continued this program to date. However, this therapy was not successful in other patients. In 1934 I tried dehydrochloric acid (decholin) intravenously in ten arthritic patients but there was no relief. This is consistent with the work of Dr. Thompson that dehydrochloric acid by itself was of no value. I hope that commercial houses will not exploit bile salts for arthritis in view of the jaundice analgesia. I look on jaundice as a temporary palliative but not as a cure for arthritis. Is it possible that there is a certain liver substance, call it *x* if you will, that may be helpful when the patient takes cinchophen without getting toxic effects but is excreted in excess if jaundice occurs and thus gives such marked relief to patients with arthritis?

DR. WILLIAM B. RAWLS, New York. During the past five years the clinic with which I am affiliated has been studying the liver function of patients with rheumatoid arthritis. Dr. Hench's report published in July 1933, pointing out the relief of arthritic pain during jaundice, suggested to us that it might be related to liver dysfunction. Although one of our patients had had relief from pain during jaundice, we had not considered a possible relationship until Dr. Hench's first report appeared. In another investigation, which included giving cinchophen as a clinical test to determine the reliability of skin tests with cinchophen, nine of the patients developed urticaria. In five of them there was almost complete cessation of pain lasting from ten days in one case to six months in another. This occurred in cases in which the urticaria was severe and lasted for more than five days. As a rule, when the urticaria was mild, either there was no relief from pain or the relief was only temporary. The galactose tolerance, hippuric acid azorubin S, bilirubin excretion, icterus index, Van den Bergh reaction, cholesterol esters, total cholesterol and albumin-globulin ratio determinations were done in most cases, sometimes before and after the administration of cinchophen. When there was relief from arthritic symptoms, the icterus index, blood bilirubin and the proportion of cholesterol esters to total cholesterol were increased. Cinchophen toxicity occurred in forty-eight patients including nine with urticaria. In fifteen of them the icterus index was determined before cinchophen was administered and again after cinchophen toxicity developed. It was increased

3 points in six patients and from 5 to 7 points in four other patients. When the icterus index remained below 10 there was no relief from symptoms or the relief was only slight and temporary. When the index was above 10, symptomatic relief was usually more marked and more lasting. Those patients with an icterus index above 10 were considered subicteric. We decided to test the accuracy of icterus index determinations. Repeated readings on a number of specimens indicated a mean technical error of 0.7. The icterus index showed a mean variation of 1.8 from day to day when taken under similar conditions. This indicated that variations of 2 or more points, such as those just mentioned, were significant. In one case in which mild jaundice developed, for two weeks there was almost complete cessation of symptoms but they returned ten days after the disappearance of jaundice. In two other cases of mild jaundice there was complete cessation of symptoms, lasting for a period of about one month. In two instances the arthritic symptoms were worse even though the icterus index was increased to 10 and 12. Our failure to obtain a cessation of symptoms as long as was obtained by Drs. Hench and Thompson is probably due to the milder degree of jaundice. As Dr. Hench has pointed out, it seems to be a quantitative rather than a qualitative action. In a number of cases there was a definite decrease in the ratio of cholesterol esters to total cholesterol after cinchophen toxicity developed. In one instance the esters were 64 per cent of the total cholesterol before administration of cinchophen and 40 per cent after symptoms of toxicity developed. The icterus index increased from 5.4 to 8.7. There was relief of symptoms for ten days. Believing that increased serum bilirubin might be a factor in these cases, we gave a number of patients intravenous injections of bilirubin, without appreciable effect on the joint symptoms. Since hearing Dr. Thompson's paper, I am convinced that this was due to insufficient dosage because our dose never exceeded 3 mg per kilogram of body weight. This dose gives only a slight increase in the serum bilirubin after four hours. Our experience with bilirubin has been rather limited, owing to the high cost of the drug. Further study is needed to determine whether increased bilirubin is responsible for the relief of pain in these patients. We have also used the sodium salt of dehydrochloric acid in a large number of patients. Ten cc of 20 per cent solution was given intravenously from two to three times each week for from four to six weeks, or until they had received eight or ten injections. Although improvement seemed to occur in some cases, it should be used only for the liver dysfunction and not as a treatment for arthritis. Its action is probably due to the increased production of the bile, which relieves some of the toxicity present. These observations suggest that the relation between jaundice and the relief of arthritic pain should receive further study.

DR. H. M. MARGOLIS, Pittsburgh. In view of the fact that the occurrence of a significant degree of jaundice, from any cause, frequently inactivates completely an arthritic process for the period of duration of the icterus, we studied the therapeutic effect of certain components of the icteric state in cases of active rheumatoid arthritis. Because it was most easily available we studied first the effect of sodium dehydrocholate, a salt of one of the bile acids, which was injected intravenously, daily, over a period of a week. We employed this procedure in several patients with rheumatoid arthritis in whom the chief disability was caused by pain, periarticular swelling, stiffness and soreness. Although, in one case, the effect during the first few days seemed encouraging, it was soon evident that improvement was merely coincidental, for the subsequent experience was quite different, and I found no appreciable benefit from the administration of the salts of bile acids. The results were so clear cut that further therapeutic trial of bile salts in arthritis was not attempted. In view of the possibility that the relation of jaundice to improvement in the arthritic state may depend on some product of hepatic degeneration we studied the effect of the intravenous and intramuscular injection of autolyzed liver which was kindly supplied me by Dr. W. S. McElroy of the University of Pittsburgh. This preparation, which Dr. McElroy has employed in the treatment of pernicious anemia, is made by adding a dilute solution of hydrochloric acid to minced beef liver to which small amounts of chloroform are also added as a preservative, the mixture being shaken, placed

in an incubator and allowed to undergo autolysis for an average period of ten days, during which time it is shaken daily. At the end of ten days the undigested material is removed by filtration and this filtrate was used after adjusting the reaction to neutrality and sterilizing it by Berkefeld filtration. Since this preparation contains various protein degradation products, which are apt to produce severe reactions, the material was diluted in physiologic solution of sodium chloride or 5 per cent dextrose solution. The intravenous injection of such an autolyzed liver solution in two cases of atrophic arthritis produced distinct exacerbation of the symptoms of pain, stiffness and soreness. During the course of a series of injections that were given, improvement did not occur, but rather an exacerbation of all symptoms. The adverse effect was so clearly evident that this procedure also was discarded. During all this time I felt that the relief of arthritic pain afforded by the icteric state is probably effected not by any one single chemical factor but probably by some combination of factors inherent in the jaundiced state. I am glad to find that Dr. Thompson's and Dr. Wyatt's observations, just reported, confirm this view to a large extent. To study the toxicity of whole bile, Dr. McEllroy and I injected intravenously into a dog a preparation of ox bile. Toxic manifestations resulted immediately, with nausea and vomiting and, later, evidence of cerebral confusion and motor incoordination, from which the dog recovered, however, within twenty-four hours. This reaction was so marked that we did not feel justified in repeating this experiment clinically, particularly since it was evident that such large amounts of whole bile would be required that it would be distinctly hazardous. That is as far as our experiments have gone, but we are still intensely interested in the problem of devising some means of duplicating that biologic state which, in spontaneous jaundice, produces these frequently remarkable clinical remissions in the arthritic patient. The report of Drs. Thompson and Wyatt points the way to further study along this line—studies which may give some clue to certain biochemical factors capable of influencing the arthritic state favorably. I can testify to one other point brought out by Dr. Hench that the effect of jaundice is somehow selective for rheumatoid arthritis and is apparently ineffective in gout. This was observed in one of my gouty patients recently in whom an acute exacerbation of gouty arthritis was preceded by an acute hepatitis with jaundice. The gouty arthritis in this case appeared, in fact, during the course of the icterus.

DR. PHILIP S. HENCH, Rochester, Minn. The authors have demonstrated a method for successfully producing an apparently harmless "jaundice" or hyperbilirubinemia, which should be of value in studying a number of physiologic and clinical problems other than ours. Their study leads to the conclusion that there is some potent reaction between bilirubin and bile salts which is responsible for the phenomenon. I have been unwilling to stress the importance of bilirubin for various reasons. Among other phenomena pregnancy, which would seem to have little or nothing to do with bilirubin, often provokes a similarly effective if less dramatic remission in atrophic arthritis. If my four patients who told me that their relief came before the visible jaundice were correct, either bilirubin is not responsible or small amounts are effective, an idea contradicted by certain data. It is of course possible that the four patients had an unrecognized visible jaundice, but if they did not have, or even if they had, a subclinical jaundice, it would suggest that significant excesses of bilirubin are not required. When his results were consistent enough and the details of his technique were ironed out, Dr. Thompson, about two months ago gave me his preliminary plan in order that I might have some experience with it to bring to this discussion. Dr. Thompson has described his technique in five sentences and the method sounds simple enough. But to me it is not as simple as it sounds. Dr. Thompson warned me that we might have difficulties at first and we have had them. First, the strong alkali continues to irritate, or cause thrombosis in our patient's veins so that the matter of giving from eight to twelve consecutive injections to the average thin, hyposthenic arthritic patient becomes a problem. According to Dr. Thompson the solution must be made fresh daily (a matter of about two hours' work), administered promptly, and kept away from sunlight at all times to prevent oxidation of bilirubin. It remains to be proved how necessary

some of these precautions are. In the eight weeks at my disposal I have been able to treat only six patients, all with active atrophic arthritis. One became jaundiced and had peaks of serum bilirubin, between 15 and 29 mg, but although he received seventeen injections (some of them in 6 Gm. 1 Gm.) he noted no relief. One received twelve injections, became definitely jaundiced, had several peaks of serum bilirubin between 10 and 26 mg, and noted only partial relief—developed and we could not give him more injections. In an attempt to avoid these reactions we buffered the solution, bringing it almost to neutrality, but two patients treated with a solution had excretion curves totally different from the others. Neutralization made the solution impotent to produce relative hyperbilirubinemia after six injections. Our last two patients have received daily doses of 1 Gm of bilirubin and 4 Gm of dehydrochloric acid to saturate them as fast as possible. They have received eleven and thirteen daily injections to date, both are decidedly jaundiced, with peaks of 24 and 34 mg of serum bilirubin and low points of 7.9 and 12.5 mg. Yet neither has yet noted any analgesia. After a few more injections, both patients experienced considerable relief from pain. One who had hydrops and fever has noted no change in these features either. Thus, ironically, I am so far from able to corroborate Dr. Thompson's findings which I should like to do, since they so amply corroborated and extend my own observations on spontaneous jaundice. In going over my records carefully with him yesterday I found two or three little differences which may be important. For example, we added bile salts before, rather than after, filtration. Nevertheless, we must conclude that the procedure is an empirical, not a rationalized, one. It is not simply a question of dissolving a certain amount of bilirubin in any alkali, adding bile salts and administering the mixture. The hypothetical τ substance may be in, or be engendered by, his solution but not by ours, although we have been using the same preparation of bilirubin and bile salts (decholin). Is the τ substance really dependent on the bilirubin-decholin mixture or is it dependent on something else in his solution? Commercial bilirubin solutions are not really pure. There are impurities in the bilirubin both of us have been using. Pure bilirubin contains 8.95 per cent of nitrogen, commercial bilirubin contains from 7.2 to 8.3 per cent of nitrogen. Whether this is a factor, whether oxidation is to be avoided or actually welcomed, these and other details are to be worked out. I am not discouraged by these preliminary differences in results. Indeed, they may help us solve the problem. In the meantime they emphasize what was said before. Dr. Thompson is not presenting us with "therapeutic jaundice" but when his method is standardized and rationalized it may help us to realize to the fullest the therapeutic implications implied in the phenomenon which has been observed to occur with spontaneous jaundice.

DR. HARRY E. THOMPSON, Tucson, Ariz. Dr. Sidel's results with bile salt given alone is similar to ours when we used bile salt alone. Dr. Rawls has used bilirubin alone but has given it in only 3 mg per kilogram doses and did not employ it in conjunction with bile salt. With regard to Dr. Hench's discussion, when we went over this procedure previous to this meeting it was quite evident that he had not followed the exact procedure which I had given him a few months previously. He had made several changes. Both he and I agree that although these are minor changes they are perhaps major in importance. This I am sure accounts for differences in results. In an effort to confirm our work he has mentioned that one patient was 50 per cent improved. This indicates to me that despite the changes made in the procedure he was sufficiently close at this time to approximate in part our results. I think that closer adherence to the procedure—both the preparation and the administration—will result in comparable clinical results. That a nontoxic jaundice can be produced is apparent, as Dr. Hench has confirmed our work with relation to reduction. Dr. Hench is to be congratulated for his keen observation that a jaundice intervening clinically may produce a remission in atrophic arthritis. I thoroughly agree that bilirubin and bile salt should be kept free from exploitation. To exploit such substances, promising as they may appear to be, is undesirable and unwarranted at this time.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1927 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Effects of Posture on Blood Pressure—Wald and his associates determined the immediate (during the first minute) and the prolonged effect (after the first minute) on the arterial blood pressure in human subjects after the change from a recumbent to an upright position. Experiments on animals trying to determine the mechanisms of adjustments were also performed. On changing from the recumbent to the standing position the systolic pressure is from 5 to 40 mm of mercury below the recumbent level about ten seconds after the change. There is a rapid recovery after this initial drop and after about thirty seconds many subjects have regained or passed the recumbent level. In some few cases the recovery is slower. Diastolic pressure usually rises slightly on standing. The same type of reaction is seen when the subjects are tilted into the vertical posture, but the drop is greater and the recovery less. Prolonged quiet standing is a severe strain on the circulation, as shown by the frequency of fainting. Reflexes from the carotid sinuses and arch of the aorta are responsible (in part at least) for the reactions leading to the recovery of the pressure.

Diagnostic Criteria of Angina Pectoris—To establish the criteria for the diagnosis of angina pectoris and to determine the frequency of atypical forms of the syndrome, Riseman and Brown made a careful investigation in 207 patients suspected of having angina pectoris. The study included the clinical history, physical examination, electrocardiographic tracings, teleroentgenograms of the heart, the basal metabolic rate, the blood serum cholesterol and the patient's reaction to exercise under standardized conditions. The five characteristics of importance in the diagnosis of angina pectoris were that the attacks were sudden in onset, short in duration involved the anterior part of the chest and inner aspect of the arms were induced by exertion in the cold and consisted of a vague indescribable

sensation of unrest or distress. Patients who lacked one or more of these features proved to have either no cardiac disorder as the cause of their symptoms or to have angina pectoris plus some complicating disease. Other characteristics encountered frequently but having no specific diagnostic value included abnormalities in the electrocardiogram, blood pressure, size of the heart, basal metabolic rate, serum cholesterol level and relief by glyceryl trinitrate. Of the patients with angina pectoris 26 per cent showed no abnormalities in the electrocardiogram, blood pressure or size of heart by x-ray examination. Angina pectoris due to valvular heart disease, paroxysmal rapid heart action, anemia or thyrotoxicosis was quite similar to that secondary to coronary artery disease, but the attacks were likely to be prolonged and frequently occurred without obvious precipitating cause. Difficulties in diagnosis were usually due to noncardiac disease simulating angina pectoris or angina pectoris simulating or occurring together with a noncardiac disease. Observation of the patient's reaction to exercise was frequently of distinct value in establishing the diagnosis or obtaining a more exact picture of the symptoms than was possible from the clinical history alone.

Congo Red in Treatment of Pernicious Anemia and Sprue—Because of the difficulty in obtaining suitable cases of pernicious anemia in relapse, the problem was at first attacked from a somewhat different angle. Barker selected from the outpatient clinic proved cases of pernicious anemia which were in a remission as the result of liver extract therapy. Weekly intravenous injections of congo red (Grübler) solution were substituted for intramuscular injections of liver extract. A 0.5 per cent solution of the dye in 0.5 per cent saline solution prepared exactly according to the method of Massa and Zolezzi was employed in all cases. Only patients without evidence of combined systemic disease were selected. Six such patients were treated with congo red for periods varying from nine weeks to six months. Five of the six patients evinced a marked tendency to relapse, as shown by a falling erythrocyte count and hemoglobin as well as by the rising mean corpuscular volume and color index. In four, distinct symptoms of relapsing pernicious anemia appeared concomitant with the characteristic changes of the blood. The symptoms disappeared rapidly and the blood levels soon returned to normal when intramuscular liver extract therapy was resumed. These relapses during therapy with congo red are the more significant in that no attempt was made to control the diets of these patients who had been previously trained to eat plenty of meat and other foods rich in Castle's

extrinsic factor The conclusion is justified that weekly injections of congo red did not furnish a practical substitute for liver extract in this group of patients, all of whom could be maintained in a complete remission by a single injection of liver extract once every two to three weeks It was also ineffective in cases of pernicious anemia in relapse and sprue The dye may occasionally produce slight nonspecific reticulocyte rises in cases of pernicious anemia

Cutaneous Irritation and Cancer—Among 100,000 active males—officers and men—Peller and Stephenson find that there occurred annually 89 ± 1 new cases of cancer of the skin or lip (actually seventy-eight cases), and there were 125 ± 0.39 deaths from each of these two types of cancer The mortality figure contains all cases with an onset of the illness during the active service of eight years (from 1929 to 1936) The peculiar conditions of life in the United States Navy—the prolonged exposure to the sun's rays, to open air and to salt water—are associated with a frequency of cancer of the lip and skin eight times the normal and a greatly diminished morbidity and mortality from all other cancers In about four tenths of the men who would be expected to die from an inner malignant manifestation there developed instead of this cancer a curable tumor of the lip and skin The mortality from cancer of the skin and lip is in the United States Navy about three times higher than in the average population (of the same age [16 to 50] group) Among the fatal cases, melanoma predominates The danger from epitheliomas is small It seems that a tumor in the inner organs develops later in only a small part of the patients in whom cancer of the lip and skin has been cured This problem must be studied on a larger scale By exposing young men to strong cutaneous irritations which are not carcinogenic to the inner organs, the lives of some who would die from a cancer might be saved, at least for a certain number of years

Tapeworm Infestations in Southern United States—Sunkes and Sellers base their report on 927,625 fecal examinations performed in thirteen Southern states There were 8,085 positive observations, making a mean incidence of 0.87 per cent The incidence in the individual states ranged from 0.29 per cent in Florida to 2.97 per cent in Tennessee Of the 7,249 positive examinations that could be classified, 98.6 per cent were the dwarf tapeworm (*Hymenolepis nana*), an average incidence of 1.1 per cent Only 100 other types of tapeworms were found in this survey, of which fifty-eight were beef tapeworm (*Taenia saginata*), thirty-two rat tapeworm (*Hymenolepis diminuta*), eight pork tapeworm (*Taenia solium*) and one each fish tapeworm (*Diphyllobothrium latum*) and dog tapeworm (*Dipylidium caninum*) Histories are given of cases of human infestation with the fish tapeworm, the rat tapeworm and the dog tapeworm Data regarding the prevalence of human infestations with tapeworm are incomplete, owing to the failure of a number of laboratories of the state board of health to classify their observations

Cutaneous Papillomatosis—The patient whose condition Wise and Sachs discuss exhibited an eruption characterized by (1) the morphologic features of individual lesions, (2) the configuration of the eruption, (3) the site of the initial manifestations and the areas of predilection, (4) the distribution of the individual lesions and (5) the concomitant manifestations (involvement of the axillae and groins) The elementary lesion consists of a papillomatous papule from 1 to 2 mm in diameter, it is slightly elevated, round, flat topped and bright red the surface is slightly cornified, and the borders are sharply defined In the course of development a rapid change takes place The red papule becomes gray, and as a result of deposit of pigment soon turns brown, the epidermis is thickened, uneven and somewhat cornified, some of the lesions are almost verrucous resembling plane juvenile warts The papules increase in size attaining a diameter of from 4 to 5 mm Further progress of the eruption results in confluence of the lesions in the form of a massed flat network with well defined borders On the intermammary and epigastric regions the eruption resembles pityriasis versicolor As the papules increase in number they gradually merge and form a centrally situated (intermammary) diffuse, even surface, while those at the periphery spread out and form a network, which diminishes and fades as it approaches the surrounding unaffected skin The earliest manifestations appear on the intermammary and epigastric regions From these areas the eruption spreads with diminishing intensity the involvement being upward toward the breasts and axillae downward toward the pubes and posteriorly up and down the spine Concomitant manifestations appear on the neck and about the axillae The skin of the neck is thickened and the surface markings are exaggerated, roughened and pigmented but papillomatous formations are lacking The skin of the axillae exhibits a pronounced exaggeration of its parallel folds the glandular orifices are prominent and enlarged and are capped with fine cornified plugs The epidermis is grayish red or grayish brown and feels smooth to the palpating finger The eruption undergoes an insidious and chronic evolution new areas becoming involved at irregular intervals The eruption

It is neither congenital nor hereditary. It seems probable that endocrinologic disturbances, especially thyroid dysfunction, may play a part in the etiology. The American literature contains no reference to this group of dermatoses.

Benign Hepatitis of Early Syphilis—Waugh cites three undoubted cases of benign hepatitis of early syphilis and one probable one. Such cases are rare. Three of the patients had secondary syphilitic lesions of the skin or mucous membranes, and one had a primary lesion. Two of them showed a Herxheimer reaction when treatment was begun with neoarsphenamine. The jaundice in all four disappeared promptly under antisyphilitic treatment. These four instances occurred among 820 cases of recent syphilis (syphilis of one year's duration or less). The chief symptom of early acute benign hepatitis in syphilis is stated by Stokes to be jaundice and the chief sign enlargement of the liver. It is distinguished with difficulty from intercurrent catarrhal jaundice of nonsyphilitic origin and from hepatorecurrence. Differentiation must rest entirely on (1) the presence of a chancre or secondary eruption (usually roseola), (2) a Herxheimer reaction if treatment is begun with an arsphenamine preparation and (3) prompt cure, if treatment is continued. From two to five weeks should be sufficient for complete recovery of the patient with early hepatitis except when there is residual enlargement of the liver. Two patients, who were treated with neoarsphenamine and a bismuth compound, had Herxheimer reactions. The patient treated with bismuth alone and the patient who received preliminary intramuscular injections of mercuric benzoate before treatment with arsphenamine showed no clinically recognizable Herxheimer reactions. It is believed that there is no danger of trouble from a severe Herxheimer reaction if an arsphenamine preparation is used from the outset in the treatment of patients with benign hepatitis of early syphilis, provided treatment is instituted with small doses of the arsphenamine preparation and the patient is watched carefully.

Clinical Course and Treatment of Sprue—Miller and Barker studied a series of thirty-three patients with sprue. Twenty-nine of these patients have been followed in the clinic after discharge from the hospital. Ten patients presented the classic picture of severe sprue with diarrhea and anemia, nine patients had diarrhea but no anemia, while fourteen complained only of abdominal discomfort and flatulence. The symptomatology, the hematology and the results of gastric analyses for these patients have been presented in detail, together with illustrative cases. X-ray study of the small intestine was made for twenty-nine of these patients and morphologic alterations of the small intestine were observed in all, these changes varying directly with the severity of the disease. The most significant

abnormalities were a distortion of the mucosal pattern and a variation in the caliber of the intestinal loops. The great majority of the patients experienced complete symptomatic relief once adequate therapy had been instituted. Moreover, these patients have been maintained in excellent health over long periods by means of a relatively simple therapeutic regimen. Five patients have returned to tropical countries without recurrence of symptoms. No patient has discontinued specific therapy entirely without suffering a relapse. The maintenance of a diet for sprue in addition to liver extract therapy gives a patient more complete relief from gastro-intestinal symptoms than does liver extract alone. The frequency of injections of liver extract must be individualized; the prevention of intestinal dysfunction serving as a guide to the amount of therapy to be given.

Traction Diverticulum of Esophagus—Wallace points out that among the ten patients reported in 1932 and in sixteen additional patients in whom traction diverticulum of the esophagus was discovered roentgenographically symptoms recurred with such frequency as to cast doubt on the theory that symptoms are absent with this lesion. Symptoms were attributed to the diverticulum by ten patients; in eight they were the patient's chief complaint while in the remaining two cases esophageal symptoms were of secondary importance. Pain behind the sternum was felt by six patients. A sensation of weight or heaviness was complained of by four and burning by three, while sudden, sharp, short, sticking dull, constant, choking and constricting were the terms used once each to describe the discomfort. Occasionally food would increase the pain. The intensity of the pain varied from mild to severe and bore no relationship to the position of the body, respiration or the time of day. Usually the pain was referred to the midsternum. Dysphagia distinct from substernal pain, was experienced by six patients. Swallowing was not only difficult but painful. Hematemesis occurred in three cases and in two it was the only complaint. Other symptoms of minor importance and infrequent occurrence were eructations, simple vomiting, hiccups, pain high in the epigastrium and weakness.

Value of Convalescent Serum in Scarlet Fever—Fox and Hardgrove in comparing the results obtained in 139 patients with scarlet fever treated with commercial antitoxin 589 treated with pooled human serum of patients convalescent from scarlet fever and 300 receiving neither but who were given the same general symptomatic treatment find that the most satisfactory results were obtained after the use of convalescent serum. When serum was given early in adequate doses, there was an apparent decrease in the mortality rate as well as a reduction in the complications. As a rule, all the symptoms improved, and there was a marked reduction in the length of time until the temperature reached normal. Serious untoward reactions following the use of human convalescent serum given either intramuscularly or intravenously, were not observed.

Amaurosis Following Appendectomy—Gjessing reports the occurrence of a case of cerebral apoplexy following an appendectomy in a man 54 years of age. The appendectomy was performed under narcosis induced with the customary

quantities of scopolamine hydrobromide, morphine and ether. During the operation the patient collapsed and became very cyanotic. After some moments, recovery occurred and the operation was continued, with the patient under the influence of an anesthetic administered by use of the open mask. When the patient awoke he was totally blind. The attending surgeon also noted paralysis of the right arm and leg. The patient was a heavy plethoric person and was restless and somewhat disoriented, so that examination was difficult. The grip of the right hand was weaker than that of the left. The other reflexes could not be examined satisfactorily. Ocular examination revealed complete ptosis of the left upper lid, the right being normal. Each eye was immobile, deviating a little toward the right but not drawn entirely to the canthus. Each pupil was round and moderately dilated and did not react to light. The media and fundi were normal. Total amaurosis was present. The patient became increasingly irrational and died during the second day following the operation. Permission for postmortem examination was not secured.

Danger to Children of Lead in Colored Chalks—Jephcott analyzed the colored chalks of five manufacturers. It was noticed that chalks of certain colors, yellow, orange and green, contained in some cases relative large amounts of lead chromate. No lead was present in white, red, blue, brown and black chalk. Cleaning blackboards and brushes in school often performed by children, will be accompanied by the inhalation of lead dust when such chalks are used. It is likely that crayons should be viewed with the same suspicion. When it is realized that not more than 0.6 Gm of metallic lead has caused a fatal case of lead poisoning, it is evident that these chalks, if continuously nibbled by children, contain sufficient lead to cause plumbism.

Acute Hemorrhagic Nephritis in Children—Yampolsky treated twenty-one patients with acute hemorrhagic or glomerular nephritis in young children at the Grady Hospital in the Negro children's ward. If the patients excreted urine without difficulty, a full diet was given. Edema was treated as follows: For a few days fluids were limited to from 500 to 600 cc daily. Magnesium sulfate was administered in doses of one-half ounce (15 Gm) every four hours until the stools became watery. Hypertonic liquids by mouth and enemas of hypertonic solution are useful. Magnesium sulfate may be given intramuscularly, from 1 to 2 cc of a 25 per cent solution for each 10 pounds (4.5 Kg) of body weight. Concentrated dextrose, 50 per cent solution, may be given intravenously. While dextrose may not have a diuretic effect, it aids materially in keeping up the patient's nutrition and also helps the blood volume. Dextrose probably aids in clearing the blood in the urine. Hypertension can best be improved by rest in bed, sedatives by mouth or intramuscularly, dextrose intravenously, and especially by the

administration of magnesium sulfate intramuscularly. If a patient has convulsions, treatment includes a tepid sponging, saline enema, magnesium sulfate, spinal puncture with intramuscularly, one-half grain (0.032 Gm.) of sodium phenobarbital or sodium amytal and 8 cc of ether in 2 ounces (60 cc) of olive oil by rectum. Occasionally transfusions are of aid. Diuretics apparently are of no great value. Focal infection should be removed. Of the twenty-one patients nine were discharged as well and nine as improved. Three died in the hospital. The author concurs with Boyle and Aldrich that the children who have recovered clinically from acute infectious hemorrhagic nephritis do not have subacute or latent nephritis.

Quinine as an Adjuvant to Prostigmin in Diagnosis of Myasthenia Gravis—In the course of some observations in relation to the antagonistic action of quinine to prostigmin, Harvey and Whitehill used the drug in establishing the diagnosis of myasthenia gravis in a case showing few objective signs. The increase in symptoms after the administration of quinine was promptly relieved by the injection of prostigmin, which had caused little noticeable change before the quinine was made prominent by the use of the antagonistic drug. That caution is necessary in giving quinine to patients with myasthenia gravis is indicated by the results in a second case, in which alarming symptoms appeared after the administration of 12 Gm of the drug, although 90 mg of prostigmin was given orally during the same period.

 Dermatitis Medicamentosa R L Sutton Jr Kansas City Mo.—p 385

Food Allergy—Rinkel discusses three aspects of food sensitization the frequency of food as an etiologic agent in the atopic syndromes and in clinical entities not yet classified as allergic diseases, the means by which one makes a diagnosis of food as a factor in these diseases and the nature of food sensitization as it affects clinical procedures He states that food is practically always a factor in pollinosis it is the most common etiologic agent in perennial nasal allergy it is almost a universal factor in asthma and in this instance it is a more common cause of symptoms in the adult than in the child Food allergy is variable in incidence and degree, it being very limited in certain patients while in others it is multiple and severe It is the multiplicity of food sensitizations that determines chronicity, it is the degree of sensitivity that determines the severity of symptoms The diagnosis of food allergy is a systematic study which neither assumes that allergy does not exist for a given food nor that food is not a factor in any clinical entity It accepts as conclusive only those symptoms which can be reproduced at will by specific foods on purposeful ingestion With this premise as a guide, the exact effect of every food in the diet is determined

Treatment of Bladder Tumors—Donohue maintains that good results in the treatment of tumors of the bladder, more than anything else depend on seeing patients early in the course of the disease Hematuria and persistent irritation of the bladder call for immediate cystoscopic examination The destruction or removal of superficial tumors by appropriate methods is rarely difficult and is followed by good results The tendency toward recurrence of these tumors should be kept in

mind, and cystoscopic examinations should be performed periodically Cases of multiple papillomatosis are often resistant to the treatment ordinarily effective in tumors of the superficial type and complete removal of the bladder should be considered Poor results in the treatment of infiltrating tumors are unavoidable when the growth is extensive There is no excuse when poor results follow the use of improper methods such as the attempt at destruction of any infiltrating growth by electrofulguration alone, whether applied transurethrally or suprapubically Treatment of infiltrating tumors depends on the location of the growth and the invasion of the wall of the bladder Segmental resection is advisable for tumors that are localized Complete cystectomy is indicated in selected cases, when there is extensive invasion of the base or vesical neck The ureters are disposed of by implantation into the skin or intestine according to conditions in the individual case Radical surgery is often contraindicated The purpose of treatment then is to alleviate suffering and to prolong life Such results may be obtained by combining suprapubic diathermy and radium implantation with postoperative high voltage roentgen treatment

Asymptomatic Scurvy, Wound Healing and Peptic Ulcer—Ingalls and Warren present twenty cases of peptic ulcer with studies of the vitamin C level in the blood plasma of these patients, point out the relation of the low values found to the deficient vitamin C intake and discuss the possible effects of asymptomatic scurvy on healing of the ulcer, on gastrointestinal hemorrhage and on wound healing following surgical operation on such patients Determinations of the amount of vitamin C in the blood plasma were made eighteen, or 90 per cent of the patients had less than the normal amount (from about 0.65 to 2 mg per hundred cubic centimeters) of vitamin C in the blood This ranged from zero to 0.6 mg, with an average of 0.19 mg per hundred cubic centimeters Only two patients showed a normal content 1.15 mg in each instance At least one reason for the low values was an inadequate intake of vitamin C Two patients have since been given massive doses of ascorbic acid with a rapid rise to normal This would seem to suggest that these patients are capable of absorbing vitamin C in a normal way and that alkaline therapy will not prevent a normal absorption if a sufficient amount of the vitamin is ingested None of these patients showed evidence of

clinical scurvy, and experience with the Sippy diet by a large number of observers has shown that the incidence of scurvy occurring in these individuals is slight. On the other hand eight of the authors' twenty patients had had gastro-intestinal hemorrhages in the past. The blood value of these patients ranged from 0.2 to 0.6 mg per hundred cubic centimeters. However, the specimens of blood were not taken at or shortly after the time of the hemorrhage, so that the exact level at the time the bleeding occurred is not known. Further studies on this aspect of the problem are being pursued. Surgical implications are accentuated when it is considered that such patients are not only often operated on many weeks after the inauguration of a dietary regimen but are subsequently maintained on intravenous fluid or milk long enough to exhaust the small tissue reserve of the vitamin that remains. Although there is no indication that a lack of vitamin C is an etiologic factor in the genesis of duodenal ulcer, it is worth while to consider the role of the vitamin in the healing of the lesion when once it is formed.

Potential Dangers of Viosterol During Pregnancy—

Brehm agrees that calcium is essentially necessary in pregnancy, but there seems to be some factor or factors when viosterol is used with it which render it either more assimilable, its retention and deposition more pronounced, or which produce an irregular mobilization, regardless of whether the calcium is given as inorganic adjuncts or by its ingestion in foods. During the last ten years he has given to his obstetric patients, except when contraindicated, 5 drops of viosterol (0.3 cc.) three times a day for two weeks and then 5 grains (0.3 Gm.) of calcium three times a day for two weeks, alternating thus every

two weeks throughout the pregnancy. Soon he began to note calcified areas in the placentas and a decrease in the size of the fontanels with fusion of the cranial sutures, which could be shown by the roentgenogram before delivery. This was easily demonstrated after delivery with a consequent lessened molding of the fetal head and an increase in the length of labors. Marked calcification was found in the kidneys of three stillborn infants without any other apparent etiology. The author then began the study of 540 obstetric cases divided equally as follows: (1) those receiving calcium and viosterol, (2) those receiving calcium alone, (3) those receiving viosterol alone, (4) those receiving calcium and cod liver oil, (5) those receiving cod liver oil alone and (6) those receiving none of the foregoing except as furnished by a normal diet. He found that viosterol causes definite calcification in the placenta, which is greatly increased by the ingestion of calcium. Cod liver oil seems preferable to viosterol. Natural vitamins when indicated seem preferable to synthetic ones. It is just as important in treating a patient not to produce by overtreatment a more serious condition than the condition originally treated. Considerable more research work is advisable before the promiscuous use of viosterol is continued.

Virus of Influenza and Neurologic Manifestations—

During the last several months, Neal and Wilcox saw a number of cases in which an acute infection of the respiratory tract diagnosed as grip or influenza has been followed within a short time by the development of various neurologic conditions. In sixteen such instances the serum of the patients has been obtained within one to three or four months after the infection in the upper part of the respiratory tract. In fourteen instances no protective antibodies were demonstrated in the serums tested for influenzal antibodies by means of the method of Francis and Magill. In one instance the serum virus mixtures indicated slight protection and in one instance a partial protection. In no instance was there complete protection. It therefore seems reasonable to assume that the original diagnosis of influenza or grip had been incorrect in at least fifteen of the cases. Further indications that the virus of influenza is not an etiologic factor in cases of encephalitis or encephalomyelitis is afforded by two facts. In a personal communication Francis has stated that in experimental animals the virus of influenza does not invade the central nervous system and Snegireff, reporting from several New Jersey state institutions in which epidemics of influenza have occurred, states that there has been no instance in which encephalitis has developed during or following influenza outbreaks of influenza. It is obvious that further work must be done to confirm or refute this opinion.

Adhesive Pericarditis—Martin submitted three patients to section of the left phrenic nerve for adhesive pericarditis. He believes that too little weight has been given to the damaging effect on the heart of diaphragmatic adhesions. Since the contractions of the heart and the diaphragm are rarely synchronous, there usually exists an opposite pull at the time of each contraction of the heart. This would certainly place a greater strain on the cardiac muscle than a pull against a rigid structure. There has also been a tendency to a rather rigid classification of adhesive pericarditis. There is no doubt a wide variation in the number, density and point of attachment of adhesions. Clinically, the important consideration is the treatment of those cases in which the heart is definitely overloaded. The characteristic picture described by Pick is not difficult to recognize and it is this condition that demands relief. These patients are suffering from chronic decompensation with massive enlargement of the liver, ascites moderate, dependent edema and a tendency to the accumulation of pleural transudate, especially on the right side. Adhesive pericarditis may or may not be associated with hypertension, rheumatic heart disease, myocardial degeneration or coronary disease. Considering only those cases with enlarged hearts, it would seem probable that the diaphragmatic pull plays a more important part in producing decompensation than mediastinal adhesions or adhesions to the anterior wall of the chest. The great strain placed on the cardiac muscle by the counterpull of the diaphragm has not been emphasized. When the pericardium is thickened or when it is greatly distended, thereby losing a certain amount of elasticity, there would be a tendency to compression of the heart with each downward pull of the diaphragm. This constriction would interfere with the normal inflow of the blood just as in the constricting type of pericarditis. There are certain cases of massive hypertrophy that are indistinguishable clinically from adhesive pericarditis. If this reasoning is correct, section of the left phrenic nerve should give a certain measure of relief in cases of this type. Since phrenicotomy presents no particular technical difficulties, it would seem to be the operation of choice in selected cases of adhesive pericarditis. In certain cases no further operative procedure may be necessary. If however, cardiomyolysis also is indicated, the preliminary phrenicotomy would not in any way interfere with its subsequent performance.

Pathogenicity to Animals of Viruses of Human Influenza—McIntosh and Selbie performed experiments from which it is evident that viruses capable of causing infection in laboratory animals can be obtained from filtered extracts from the lungs of cases of human influenza. It also appears that these viruses are partially neutralized by convalescent influenzal sera, and some degree of protection was afforded by an immune serum (IH) prepared against the influenzal virus of Smith, Andrewes and Laidlaw. Much more work has to be done on the relationship of these various viruses before their correct relationship is known. The evolution of a typical disease seems much slower with the authors' strains than with those of Smith, Andrewes and Laidlaw. In the ferret there is the usual initial rise of temperature in the first few days after the inoculation, but the secondary rise is delayed till the tenth to the fourteenth day or even longer. It is at this period that the characteristic changes of the lungs are most definite. But as Smith and his colleagues have made a point of carrying on the passages at short intervals, their virus may have adapted itself to such a procedure. In their case a local and superficial proliferation of the virus occurs, while the authors, on the other hand have allowed time for a more general invasion of the tissues, and particularly those of the lungs.

Epidemic of Paratyphoid B Fever in Liverpool—Frazer and his associates discuss an outbreak of paratyphoid B fever that occurred in Liverpool and Bootle at the end of 1936 and beginning of 1937, with 123 cases and eleven deaths. An additional nine cases in rural districts were also considered to be connected with this outbreak. The circumstances of the rise and decline of the epidemic were compatible with the belief that it was due to the infection of loaves of bread by a carrier of Bacterium paratyphosum B who handled the bread consumed by 62 per cent of the patients. The isolation of the causal organism from the stools of patients proved to be a great aid to diagnosis so early in the illness as the first week. Positive stools were presented by 50 per cent of the patients in the seventh week of illness and 20 per cent were still excreting the organism in the ninth week. Ninety-five strains of Bacterium paratyphosum B isolated from forty-eight patients fell within Kristensen and Boylen's group R₁. The survival of Bacterium paratyphosum B on bread crusts was established. With few exceptions patients made uneventful recoveries. In

children the onset was abrupt with abdominal symptoms simulating an acute condition of the abdomen. Three patients, adult women, persisted as carriers for five months or more.

Diffuse White Matter Gliosis in Mental Defectives—Meyer and Cool studied histologically seven low grade defective subjects showing gross neurologic lesions, six microcephalic persons with spastic diplegia and severe mental defect, two able-bodied microcephalic patients without gross neurologic signs, one simple able-bodied idiot and six mongols. The gliosis of the white matter was observed in cases in which there was a demyelinated condition of the globus pallidus, marbled condition of the striate body, and in related progressive conditions, commencing at birth or in infancy. In all the cases the gliosis showed no difference from that seen in conditions of adult life, and there were none of the developmental errors of the immature or blastomatous characteristic of the glia cells, such as are to be seen in tuberous sclerosis, von Recklinghausen's disease, and the like. In the microgyric brains, the appearance of the white matter gliosis in regions in which cortical disturbances were negligible, e g, in the cerebellum, suggests that the gliosis was not secondary to the malformation of the cortex. More often than is realized developmental arrest is only the indicator of the time of the damage and not the expression of an intrinsic, abiotrophic or faulty tendency of the tissue. In many of the cases there is some evidence suggesting that a vascular factor or some other type of defective tissue oxygenation might be the immediate cause of the pathogenic change. In one of the mongols the Sommer sector of the horn of Ammon showed a well marked sclerosis, and, in addition, there were in the mongols and other cases perivascular changes as well as diffuse lesions. Defective tissue oxygenation is often merely a final common pathway of etiologically different disease processes. The observations in these cases give a forcible warning against indiscriminate use of such brains for comparative purposes, e g, measurements of the cortex, which are liable to grave error unless a systematic investigation of the whole brain is made. This restraint should not obscure the fact that the extremely high incidence of lesions within the white matter adds a new feature to the pathology of mental deficiency. Any research into the pathogenesis of mental deficiency requires impartial examination of all parts of the brain.

Excretion of Vitamin C in Osteomyelitis—Abbasy and his collaborators have shown that in 193 patients suffering from juvenile rheumatism, eighty-eight cases of surgical tuberculosis and cases of colds and influenza a marked deficit was present in the amount of vitamin C excreted in their urine as compared with sixty-four control subjects receiving the same dietary intake of the vitamin. The infected subjects likewise gave a consistently diminished response to test doses of the vitamin. In seventeen active cases of osteomyelitis, seventeen half-healed cases, sixteen healed cases and ten controls the range of values for the excretions of vitamin C by the active cases was only about one half of that of the control cases—viz, from 9 to

15 mg daily as compared with from 20 to 40 mg daily. Whereas the control cases were all well above the standard level of excretion (average 26 mg daily), 10 per cent of the active cases were below the standard (average 116 mg daily). Healed cases were normal in their excretions and half-healed cases were intermediate. The control and the healed cases reacted well on the first day to doses of 700 mg per 140 pounds (63.5 Kg), while the active cases did not react until the second or third day. The degree of subnormality in the vitamin C titer goes roughly parallel with the severity of the infection, and, correspondingly, the better healed cases show a more adequate output of vitamin C than those in the earlier stages of healing. Osteomyelitis like the other infective conditions examined, causes a marked diminution in the vitamin C reserves or degree of saturation. The patient when healed returns to normal in his usage of vitamin C and there is no evidence of a condition of latent infection seen in acute rheumatism.

Influence of Infection on Vitamin C Content of Tissues—Harris and his associates studied the effect on the excretion of vitamin C in guinea-pigs infected with *Bacterium aertrycke*, *Pasteurella pseudotuberculosis*, *diphtheria toxin* and *Mycobacterium tuberculosis*. Estimations were made of the amount of vitamin C in the adrenals and liver. The titration of the organs for vitamin C were carried out by the microchemical method of Birch, Harris and Ray. A considerable diminution was observed in the amount of vitamin C present in the adrenals as compared with controls which had received the same dietary intake of vitamin C. The vitamin C in the liver was not significantly affected. In the more chronic tuberculous infection in guinea-pigs there was a diminution in the amount of vitamin C in the adrenals and also some fall in the concentration of the vitamin in the liver.

New Diluted Schick Fluid in Diphtheria Immunization—Merrillees has used a new diluted (8.4 Gm of boric acid, 15.9 Gm of sodium chloride, 5.7 Gm of borax, 5 Gm of purified gelatin and 2 liters of distilled water) diphtheritic toxin in the Schick test of 5,000 children. The test is done in the usual way by injecting an intradermal dose of 0.2 cc. into the flexor arm. The result is read on the fifth or sixth day and has a characteristic appearance. There are three stages of reaction: the immediate reaction, the second day reaction and the first day reaction. To avoid ambiguity the day of injection is the first day. The immediate reaction appears suddenly within a few minutes and fades just as quickly. It varies in intensity and appears to have no relation to any specific reactions. Read on the fifth day, a normal Schick reaction with a new product is seen as a striking patch of redness on a normal skin. There is practically no infiltration, there is no areolar paleness and there is no tenderness or pain. The color is best described as that of a moderate sunburn. Although the color varies in intensity, the diameter is always about 2 cm. In reading the test, good diffused white light is necessary and stretching of the skin must be avoided. A normal pseudoreaction cannot be confused with a Moloney reaction. A large proportion of pseudoreactions are observed. They are of two types, according to whether they resemble the Moloney or Schick reaction. The former is merely a mild Moloney reaction and is found only in those who react to the Moloney test. The other is discovered by a control of heated Schick reaction. It is of little practical importance, as it fades before the first day, when the true Schick reaction is easily read.

—p 397
- *Behavior of Blood Sugar in Women During Intermenstrual and Menstrual Period T S Auerbach—p 419
- Experimental Studies on Anemias Provoked by Protein Shock in Rabbits M Millet—p 437

Effect of Colchicine on Coagulation of Blood—Loicq shows that colchicine in a dose of 3 mg per kilogram produces in rabbits a reduction in the number of leukocytes which is secondarily followed by an increase occasionally as considerable as a leukocytosis, which attains its maximum from eight to twelve hours after the administration of the substance. In the course of the phase of colchicine hypoleukocytosis there is always a more or less pronounced acceleration of the time of recalcification of recalcified oxalated plasma. On the other hand, in the course of the hyperleukocytic period there is a retardation of the time of coagulation of the recalcified oxalated plasma. The appearance of the serozyme (first phase of the coagulation) takes place within the normal delay of the primary period of hypoleukocytosis determined by the colchicine and is retarded during the period of hyperleukocytosis. The cytozyme-serozyme reaction, which gives rise to thrombin (second phase), is hardly modified in the course of hypoleukocytosis, while it is considerably retarded and at times even totally prevented in the animals with postcolchicine hyperleukocytosis. The action of thrombin on the fibrinogen (third phase) is produced with the same rapidity before and after the administration of colchicine whether the animal is in the period of hypoleukocytosis or of hyperleukocytosis. The transformation of fibrinogen into fibrin under the influence of thrombin is accomplished normally after the administration of colchicine, whatever may be the number of leukocytes of the circulating blood. The retardation observed in the coagulation of the blood after the administration of colchicine depends purely on an augmentation of the antithrombins acting on the first and second phases of the coagulation of the blood. The number of blood platelets diminishes in the course of the hypoleukocytosis but rises again afterward and during the phase of postcolchicine hyperleukocytosis gives values that are lower than or greatly exceed the normal ones. Sodium nucleate produces a marked hyperleukocytosis, which is always accompanied by a considerable retardation of the formation of the coagulum at the time of the recalcification of the oxalated plasma taken fourteen hours after the administration of this product in a dose of 250 mg per kilogram of body weight.

Blood Sugar During Intermenstrual and Menstrual Period—The observation that in some women a craving for sweets increases shortly before or during menstruation induced Auerbach to investigate whether this subjective manifestation has objective causes the more so since this craving for sweets during the menstrual period was observed also in women who ordinarily were not particularly fond of sweets. Blood sugar tests were made on forty-nine women during the intermenstrual and during the menstrual period and control tests were made on six men. First the blood sugar was determined while the persons were still fasting. Then 50 Gm of dextrose was given in 200 cc of tea and blood sugar tests were made after thirty, forty-five, sixty, ninety, 120, 150 and 180 minutes. It was observed that in the women the blood sugar curve varies during the different phases of the menstrual cycle and that there are two types of curves. In one group of women the blood sugar is lower during the menstrual than during the intermenstrual period. In a second group it is higher during the menstrual period. The curves observed in men differ on the average from those of women. Discussing the results of these tests the author points out that the women who had the first type of blood sugar curve (lower during menstruation) had a greater amount of fatty than of muscular tissue whereas, in the second group the amount of muscular tissue was comparatively greater. In view of the fact that the adrenals influence the development of the musculature as well as the carbohydrate metabolism it is suggested that the adrenal cortex plays a part, in that the greater fluctuation in the blood sugar and the greater craving for sweets is the result of a relative weakness of the adrenal cortex.

- When and How to Employ Vaccination with BCG J Paraf and Boissonet—p 1307
- *Clinical Form of Arterial Hypertension Pseudotumoral Hypertension J Dereux—p 1309

Pseudotumoral Hypertension—Dereux points out that certain patients with arterial hypertension present themselves for examination with a syndrome of intracranial hypertension. These patients have ordinary or malignant hypertension but what dominates in them is the intracranial hypertension. This hypertension governs the clinical aspects and everything else is incidental. This particular development of arterial hypertension makes of this clinical form a distinct entity for which the author suggests the term "pseudotumoral arterial hypertension." After showing why this form of hypertension presents a special entity, the author discusses the symptomatology, the pathogenesis and the etiology. He reaches the conclusion that, whatever may be the pathogenic mechanism or whatever may be the etiology, this form requires a special treatment, namely, one which combats the intracranial hypertension. When the syndrome of intracranial hypertension has been recognized in a patient with arterial hypertension and when the examination of the fundus of the eyes has revealed a papillary stasis, it is necessary to combat the hypertension of the cerebrospinal fluid. During the first period the author recommends lumbar punctures and injections of hypertonic solutions and during the second period decompressive trepanation.

- Who Were the Precursors of Forlanini in Artificial Pneumothorax? O M Mistal—p 802

New Reading of Sedimentation of Erythrocytes—Carez and Wynants describe experimental and clinical studies on the sedimentation speed of the erythrocytes. In the clinical studies they give especial attention to tuberculous patients. They show that two sedimentations of the same value when measured by the hourly average may differ completely if their behavior is studied at fifteen minute intervals. Some become progressively accelerated, in others the rapidity remains uniform and in still others there is a retardation at the end of the reaction. As a general rule in laboratory as well as in clinical experiences, a reaction of the accelerated type indicates that the sedimentation is more rapid in comparison to its real value, a retarded reaction shows that the hourly value of the sedimentation is inferior to that which it should be in reality. The type of the hourly curve thus corrects generally the technical or physiopathologic causes which modify the rapidity of the true sedimentation. The juxtaposition of the two modes of reading the hourly curve and the hourly average give values that are of greater importance from the diagnostic and prognostic point of view than are obtainable by Westergren's method.

- Cutaneous Emphysema After Cesarean Operation H Schlesinger—p 66

Aspects of Arrhenoblastoma—Foderl reports the history of a girl who from her fifteenth year on developed some secondary male sex characters—deep voice hairgrowth and so on. At the age of 17 she asked medical advice on account of a hard tumor below the umbilicus. Laparotomy disclosed a tumor on the left ovary. The adnexa of the left side were removed. Twenty-four days after the operation the first menstruation set in. The male hairgrowth and other male characteristics disappeared. The histologic examination of the surgical specimen disclosed an arrhenoblastoma of type II of R Meyer's classification which is characterized by solid cordlike epithelial

proliferations, which pass into diffuse proliferations and have a sarcomatous structure." In discussing the problem as to how a gonadal cell group can undergo sexual change and assume male characteristics, the author emphasizes that an analogous gonadal tumor in men is unknown, that is, there is no testicular tumor which causes the development of female characteristics in men. In view of the fact that the female cells have two sex chromosomes whereas the male cells have only one, it may be assumed that from the germ cell with female factors male cells may develop if, in the course of the atypical because blastomatous cell division, one sex chromosome will get lost, however, germ cells with male determination can never turn into female cells, because the required chromosome is not present.

*Effect of Calcium on Amount and Acidity of Gastric Secretion C. Cella—p. 381

Effect of Calcium on Gastric Secretion.—Cella made determinations of the gastric secretion of normal persons and of patients suffering from increased or decreased gastric secretion. In resting persons with a fasting stomach fractional withdrawal of the secretion was performed before and for two hours after administration of an intravenous injection of 1 cc, 2.5 cc or 10 cc of a 10 per cent calcium chloride solution or 10 cc of a 10 per cent calcium gluconate solution, respectively. The author concludes that, owing to its sympathicotropic effects, calcium modifies neither the amount nor the acidity of gastric secretion of normal persons. The same dose of calcium which stimulates the gastric sympathetic system of one person may paralyze that of another one according to their individual sympathetic excitability. It may also cause the opposite effects in the same person if the sympathetic excitability of the person changes. The paralyzing action of calcium on the sympathetic of the stomach takes place especially on administration of a large dose (1 Gm. of calcium chloride). However, small doses of calcium (from 0.1 to 0.25 Gm. of calcium chloride or 1 Gm. of calcium gluconate) may also paralyze the gastric sympathetic

Exchanges of Water in Lungs in Decompensated Heart Disease.—Calabresi and Rocchini determined the amount of water eliminated in the expired air in a group of patients having heart disease in decompensation and also in normal persons for control of the results. The patients suffered also from disorders of the water metabolism but the respiratory rhythm was regular. The determinations were made several hours after meals on resting patients who were trained to breathe through a Krogh valve. They expired through a system of flasks which contained sulfuric acid in which the air was dried. The amount of water eliminated in the expired air was determined by the difference of weight of the flasks containing the sulfuric acid before and after expiration. The authors found that the exchange of water in the lungs of the patients is normal. The amount of water eliminated in the expired air is about 85 per cent of the values of saturation in normal persons as well as in patients having heart diseases, provided the respiratory rhythm of the patients is normal. It depends on the humidity of the inspired air and the intensity and rhythm of respiration. The authors conclude that the diminished extrarenal elimination of water that establishes itself in patients with decompensated heart disease depends on defective elimination of water through the skin at the edematous zones. Blood does not retain water

from the air. Stasis of the lung does not prevent elimination of water through respiration. The statement in the literature about extrarenal retention of water in heart diseases being due to modifications of the physical and colloidal properties of the tissues by which the latter retain water from the blood is not supported by the results of the authors' studies. They also determined the amount of water in mixed venous and arterial blood of patients suffering from decompensated heart disease. The existence of stasis of the lung and the lack of absorption of water by the blood in the lung were verified.

Beneficial Effects of Some Pulmonary Perforations G. Giusti—p. 601

Modification of Tubercle Bacilli by Short Waves.—Menotti subjected cultures of living virulent tubercle bacilli to irradiation with short waves (8 meters long) for two, four, six and eight hours. From the different cultures transplants were made on Petraghani's medium. Irradiated cultures, especially those which were irradiated for six or eight hours, developed exuberantly in comparison with nonirradiated cultures of the same type of bacilli. One group of guinea pigs and a group of controls were given intraperitoneal and subcutaneous injections of 1 cc of a 1:10,000 or a 1:2,000 suspension of irradiated and nonirradiated tubercle bacilli, respectively. The controls were killed ninety-four days after inoculation and showed common experimental tuberculosis. The animals which were inoculated with irradiated cultures, both those which spontaneously died and those which were killed ninety-two or ninety-five days after inoculation, showed at necropsy intense tuberculosis, which was proportional to the duration of the irradiation of the cultures. Four groups of guinea pigs and a group of controls were hypodermically inoculated with suspensions prepared from irradiated and nonirradiated cultures of tubercle bacilli. The animals were given a total number of ten injections of 1 cc each of a 1:1,000,000 tubercle bacillus suspension at intervals of five days. Suspensions prepared from irradiated cultures were given to the animals in four groups, whereas those in the control groups were given the suspension of nonirradiated cultures of the same type of tubercle bacilli. The animals in each group were left at rest for twenty days and then subcutaneously inoculated with 0.25 mg. of living tubercle bacilli. The animals which were inoculated with suspensions from irradiated cultures had an infiltration reaction at the point of inoculation which did not develop in those treated by a suspension from nonirradiated cultures. They lost more weight, died sooner and developed more intense and extensive tuberculosis than the controls. At necropsy it was found that frequently there were intraperitoneal and intrapleural effusions, great hypertrophy of the liver and the spleen, complete involvement of the lung by tuberculosis, processes of caseation at the internal aspect of the peritoneum and the presence of abundant subcutaneous gelatinous exudates. The author concludes that irradiations of short waves have neither an abiotic nor an immunizing action on tubercle bacilli. They have a stimulative action which is proportional to the duration of irradiation of the cultures used in inoculating the animals.

*Epidemic Encephalitis in Patients Who Previously Have Had Poliomyelitis W. Klimke—p. 1413

Epidemic Encephalitis and Poliomyelitis.—Klimke says that the development of epidemic encephalitis in patients fifteen or twenty years before have had acute anterior poliomyelitis from which paresis and atrophies still remained raised

the question whether a person who has passed through acute anterior poliomyelitis is more likely to develop epidemic encephalitis in later life than a person who has not had poliomyelitis. Investigations have shown that from the anatomic point of view relations exist between epidemic encephalitis and acute anterior poliomyelitis in that they represent nonsuppurating encephalitides or encephalomyelitides, and since the gray substance is most severely involved they should be referred to as polioencephalitides and polioencephalomyelitides. However, the author shows that from the etiologic, epidemiologic and clinical point of view poliomyelitis and epidemic encephalitis present distinct disease entities, in spite of the similarities in the anatomic aspects. The question of the relationship between poliomyelitis and encephalitis was first raised by Neustaedter, Hala and others, who observed positive complement reactions between the cerebrospinal fluid of encephalitis and the virus of poliomyelitis as antigen and who successfully treated encephalitis with antipoliomyelitic horse serum. From these observations they concluded that poliomyelitis and encephalitis are caused by varieties of the same etiologic agent. The author, however, states that the effectiveness of serotherapy cannot be regarded as a proof of relationship, since in poliomyelitis as well as in encephalitis therapeutic results can be produced also with non-specific serums. Moreover, an antipoliomyelitic horse serum is nonspecific, because poliomyelitis cannot be transmitted to horses and consequently no specific serum can be obtained from horses. The author reaches the conclusion that a person who has had poliomyelitis is not more susceptible to encephalitis than are other persons and that the two diseases are distinct entities.

Changes in Blood Vessels of Tissues Irradiated with Roentgen Rays F Windholz—p 662

Radioactive Substances in Treatment of Hemangiomas—Müller reports observations on thirty-nine cases of hemangioma in which irradiation was used. Twenty-eight of the patients were less than 1 year old. The most frequent localization of the hemangioma was the region of the eyelids, the root of the nose and the lips. In other cases the hemangioma was on the forehead, cheek, head, neck, shoulder, chest or foot. Functional disturbances existed in the cases in which the hemangioma was on the eyelids (impairment of vision) and on the lips (difficulties during intake of food). The irradiation always established normal function. In all cases except those of naevus flammeus the coloration could be changed so that either the normal skin color was approached or a whitish scar resulted. Pure hemangiomas have a great sensitivity to rays and can be made to disappear with doses that exclude the possibility of impairment of the child. In angiofibromas the ray sensitivity decreases in proportion to the amount of fibrous tissue. It is inadvisable to precede the irradiation by other treatments (diathermic impuncture, coagulation or carbon dioxide snow) which are likely to cause fibrous transformation in the tissue. In all but two of the cases the cosmetic results of the irradiation were satisfactory. The author generally employed radium contact or distance irradiation, depending on the extension of the hemangiomas. Moulages produce a uniform effect and smooth scars in case of extensive superficial hemangiomas. In a few cases, larding with thorium X or with radon capillaries had to be added. The latter methods are avoided as much as possible, particularly if the hemangioma has a smooth surface. The larding was never repeated. The contact irradiation was applied by means of tubes containing 10 mg of radium element. The completion of the treatment generally required a year

The aim was to use as small a dosage as possible. The first irradiation might effect only arrest of the process or a slight paling. After from six to eight weeks the treatment was repeated and the third and fourth irradiations, which usually effected the desired results, were given after intervals of several months.

Changes in Blood Vessels Following Roentgen Irradiation—Windholz says that the fact that the terms productive endarteritis or panarteritis have been applied to the vascular changes resulting from roentgen irradiation implies that they are localized exclusively or chiefly in the arteries. To learn more about the condition of the veins, he made microscopic studies on the tissues surrounding an x-ray ulcer on the abdomen of a man who had died as the result of gastric carcinoma with hepatic metastases. It was found that in the superficial layers near the ulcer the capillary vessels, the precapillaries, the small arterioles and the venous blood vessels showed the same changes, whereas in the deeper layers (from 1.5 to 2 cm from the surface) the venous blood vessels showed more frequent and severe changes than did the arterial vessels. There were small arteries without microscopically demonstrable changes, but the accompanying veins were completely or partly obliterated and the venous walls were greatly changed. In the still deeper (subserous) tissues (3.5 cm from the surface) the arteries were entirely free from changes, whereas the walls of the accompanying veins showed in some parts a honeycombed structure. Since the studies in this case the author has investigated the behavior of the arterial and venous vessels in numerous irradiated tissues and in many, although not all of them, he has found extensive processes of obliteration in the veins, when the arteries were entirely free from changes ascribable to irradiation. Further studies are necessary to demonstrate what role the greater ray sensitivity of the veins has in the complex of the general reaction of the tissues to irradiation.

*Dystostosis Multiplex Leonore Liebenam—p 91

Roentgenologic Changes in Rachitic Children—Kilian shows that pathologic changes are demonstrable in the scapula in a rather high percentage of cases of rickets. However, the roentgenologic demonstration of these changes is not possible in all x-ray exposures. A good survey is possible if the exposure is made while the arms of the patient are held forward and upward at an angle of approximately 135 degrees to the axis of the body. The changes are nearly always bilateral. They consist of inward bending of the scapula, of zones of transformation, of cuplike fringing, as on the end of the shafts, and so on. The changes are caused by the disproportion between the resistance of the bone and the mechanical exertion by the musculature. The muscles which cause the inward bending are the lower part of the anterior serratus and the rhomboid muscle. The subscapular muscle is less important in the bending of the scapula. If the process of decalcification is far advanced, bending of the scapula is produced not only by the aforementioned muscles but also by the rhomboides minor, the levator scapulae and the upper portion of the subscapularis. These two groups of muscles may produce bending over of the margo vertebralis. At the sites of greatest traction, zones of transformation may develop in the bone, that is, the lamellar bone, which is extremely sensitive to chronic traction, is absorbed and replaced by reticulated bone. The roentgenogram gives the impression of a division in continuity, which however, has smooth outlines and also lacks other typical symptoms of fracture. If the rachitic process is followed by cure, calcium is deposited in the zones of transformation. Since these calcium deposits enter into an unusually dense osteoid tissue, a later

roentgenogram reveals a surprisingly strong calcium shadow. As the rickets is cured, the deformities of the scapula largely disappear.

Multiple Dysostosis—Hurler reported in 1919 two cases with multiple defects, chiefly in the skeletal system, to which he gave the name dysostosis multiplex. Liebenam describes a case of her own. The patient was one of a pair of binovular female twins, and at the time when the first examination was made she was 13 years old. Whereas the second one of the twins showed normal development, the first one gave the impression of a child 6 or 7 years old, except that the head was unusually large. Retardation in the growth of the first twin was noticed between the second and the third year of life. Complete cessation in the growth in height allegedly took place between the sixth and seventh years of life. The mental development was unimpaired. The school work of the twin sisters was about the same and was above the average of the class. The twin with the retarded physical development complained often of backache and of impaired movement in most joints. The disturbances were especially noticeable during bending, climbing stairs and on attempting to lift the arms above the horizontal line. The child tired easily and frequently complained of dizziness and headaches, particularly above the eyes. Vision and hearing became impaired. Examination of the twins disclosed many defects in the child with retarded development. Examination of the eyes revealed turbidities in the cornea and hypermetropia. The hearing capacity was slightly impaired. There was a considerable curvature of the vertebral column. The deformities in the extremities were symmetrical and involved chiefly the *jointa-articular* portions. The examination of the nervous system disclosed nothing abnormal. In the course of the following eighteen months the differences between the twins increased. There was little change in the one with the retarded development. Temporary treatment with a thyroid preparation was followed by dizziness, headache, diarrhea and loss of weight and was discontinued. Improvement in the movements and in the physical activity of the child is ascribed to intensive active and passive exercises. Twenty cases of Hurler's multiple dysostosis have appeared in the literature. This number includes seven cases which were recorded in the English literature under the term gargoylism. Children with multiple dysostosis usually come from healthy families. Disproportionate dwarfism is the usual physical habitus. Other characteristic aspects are enlargement or malformation of the head, veil-like turbidities of the cornea, thoracic deformities and articular changes. Disturbances that are frequently observed in these patients are hernias, enlargement of the liver and spleen, hypertrichosis and hardness of hearing. The author further shows that dysostosis is a sharply defined disease entity which belongs to the large group of degenerative dysostoses.

 Clinical Aspects and Therapy of Gonorrheal Arthritis E Wanderer—p 1300
 Temporary Interruption of Diabetes During Pregnancy A Forro—p 1303
 Clinical Aspects and Therapy of Uremia R Bauer—p 1305

Modification of Micro-Organisms by Irradiation—Wertheim points out that the objection has been raised that the effects he produced on micro organisms with short waves or ultrashort waves can be explained by the action of heat. He replies that careful measures were taken to exclude the effect of heat. Then he reviews the behavior of a number of bacteria and fungi in the short wave field. It was found that the same micro-organism is influenced differently by various wavelengths. Some wavelengths cause inhibition of growth, others promote growth and still others do not produce any change. Organisms of the dysentery, coli and Salmonella group have a considerable degree of resistance to short waves, but staphylococci and streptococci are rather sensitive. The latter are readily injured by irradiation with wavelengths of 15 meters. This observation has been therapeutically utilized in suppurating and septic proc-

esses. Further the author describes how the life process of yeast are influenced by short rays. He concludes that the reported results prove once more the specificity of certain wavelengths.

 Causes of Pseudarthrosis and Retarded Callus Formation Nasty E. Cases G Ya Epshteyn—p 550

Procaine Hydrochloride Block—Vishnevskiy regards the effect of procaine hydrochloride block on the disease process in the nature of chemical neurotomy. One advantage of the block is that the interruption of the pathways between the central nervous system and the periphery is more complete than with surgical neurotomy. In the latter there remain a number of pathways after the nerve has been severed. The disadvantage of the method is the brevity of its action. The clinical results obtained by procaine hydrochloride block in various dystrophic processes were not inferior to those obtained by section of the nerve trunks. The author later extended his clinical trials to processes localized in various regions of the body by attempting to influence the nervous system by the application of the block at a distance from the diseased focus. The method was successful in erysipelas, edema of the larynx, dysentery, acute epididymitis, furuncle and carbuncle, as well as in dystrophic processes of neurogenic character. Because the favorable influence was most marked in the inflammatory processes, the author assumed the existence in it of a neurotrophic component. According to his hypothesis it is this component that is influenced in a favorable direction, the procaine hydrochloride block acting as a mild stimulant of the central nervous system. Conservative treatment by a brief procaine hydrochloride block of the nerves of localized superficial inflammatory processes of the skin, such as adenitis, furuncle and carbuncle, were invariably successful. Early puerperal mastitis was aborted in every instance in twenty-four hours. Paralytic ileus responded readily to lumbar procaine hydrochloride block, particularly when that disturbance of the vegetative nervous system was due to an inflammatory focus.

- *Occurrence of Myelocytes in Normal Human Spleen A Bertelsen—p 929
 *Sedimentation Reaction of Blood E Worsaae—p 944
 Pulmonary Air Cyst Case T V Hysge—p 950

Myelocytes in Normal Human Spleen—Of the thirty four spleens examined by Bertelsen, neither history nor post mortem suggested anomaly in blood formation or spleen. He says that eosinophil myelocytes were confirmed in all cases, neutrophil myelocytes in ten cases and basophil myelocytes in seven. In six cases there were basophil leukocytes and in all cases eosinophil leukocytes, in fifteen cases in far greater number than simple apportionment of these cells between blood and splenic pulp can apparently explain. Since the literature contains no report of eosinophil or basophil myelocytes found in the normal blood, while myelocytes are a constant constituent among the cells of the pulp of the spleen, the author believes that the myelocytes are formed locally, either by myeloid separation from the large lymphocytes (unitarism) or from reticulum cells in ungranulated preliminary stages (polyunitarism).

Sedimentation Reaction of Blood—Worsaae studies the relation between the sedimentation reaction and the plasma content of proteins shows that increased fibrinogen content always caused increased sedimentation reaction. With increase in fibrinogen, increased sedimentation reaction can result from increase in the globulin content, but this does not always follow. There is no certain correlation between the hemoglobin percentage and the sedimentation speed.

ANTRAL GASTRITIS AND SPASM

CHAIRMAN'S ADDRESS

ROSS GOLDEN M.D.

NEW YORK

During the past decade an increasing volume of information concerning inflammatory conditions in the stomach has been provided by histologic studies of freshly resected material and by increasing use of the Wolf-Schindler flexible gastroscope. Henning¹ stated that gastritis is the commonest disease of the stomach. Because it is the daily task of the radiologist to search for causes of digestive disturbances, it seems desirable to examine, from his standpoint, the evidence concerning this disease and to correlate the pathologic changes with those demonstrable by roentgen methods.

A review of the histology of gastritis as presented by experienced workers in the field (Faber,² Konjetzny,³ Henning¹ and others) and of other phases such as etiology, classification and treatment, cannot be attempted here. Only the aspects will be discussed which bear directly on the problem of x-ray examination of the stomach.

Gastritis is an inflammation of the gastric wall of as yet unknown etiology, which begins in and may be limited to the mucosa but which frequently extends to the deeper layers even to the serosa. The disease may be generalized throughout the entire stomach but is often limited to only its maximum effect in the antrum (Faber²). As far as motility is concerned the antrum, or "canalis egestorius" (Forssell⁴) is the most important part of the stomach, therefore inflammatory changes in that region may produce serious disturbances in gastric function. This has naturally led to the use by many writers of the term "antral gastritis" or some similar expression such as "pyloritis" or "pyloric gastritis." Gastritis may produce any or all of the symptoms of peptic ulcer including hemorrhage (case 1 fig 1), which may be slight, severe or even fatal (Konjetzny³ Benedict⁵) pain vomiting and loss of weight may suggest malignant disease.

From the Department of Radiology of the Presbyterian Hospital and of the College of Physicians and Surgeons of Columbia University.

Read before the Section on Radiology at the Eighty Eighth Annual Session of the American Medical Association Atlantic City N. J. June 9 1937.

DIAGNOSIS

The diagnosis of gastritis depends mainly on the gastroscopic and the x-ray examination. The experienced gastroscopists (Schindler,⁶ Henning¹, Schloss Ettinger and Pratt⁷ and others) agree that in many instances no change takes place in the mucous membrane which can be demonstrated by x-ray methods and that in such cases the disease can be detected only by gastroscopy. Henning warned particularly against the interpretation of wide exaggerated mucosal folds as "hypertrophic" gastritis.

There is ample evidence however that in many cases gastritis produces changes in gastric form and function, demonstrable by the barium sulfate meal which the radiologist must be prepared to recognize. A brief review of the normal movements of the lower end of the stomach is a necessary preliminary to a discussion of these changes.

THE MUCOUS MEMBRANE AND THE ANTRAL SISTOLE

As the narrow peristaltic wave enters the antral region, its relaxing edge decreases and its contracting edge increases in speed closing off a portion of the lower end of the stomach and under normal conditions resulting usually in the expulsion of gastric contents. Then the wall relaxes promptly and the lumen returns to its normal width and contour. This is known as the antral systole. Observations on a dog's stomach made in this department⁸ after the placing of opaque markers beneath the serosa suggest that the antral systole is associated with a contraction of the longitudinal muscle toward the pylorus. Schindler,⁶ from gastroscopic observations, described shortening of the antrum with antral peristalsis.

The normal mucous membrane of the stomach is freely movable over the muscle. This is easily demonstrated by palpation of a fresh specimen by the separation of mucosa from muscle wall when the stomach is opened at necropsy and by the projection of the mucous membrane over the edge of the muscle when the living stomach is cut at operation. Forssell⁴ has shown that the formation of mucosal folds is the result of independent contraction of the muscularis mucosae. Obviously this independent movement is contingent on the mobility of the mucous membrane and an intact muscularis mucosae. In some cases the mucosal folds in the antrum run irregularly transverse

to the long axis of the stomach, and when the antral systole takes place they appear to change direction (fig 2) and run neatly parallel with the long axis. I have observed this phenomenon in the dog's stomach as well as in the human stomach. (It is more easily seen in the small intestine.) For this change to occur, a movement of the mucous membrane in a cephalad direction must take place, thereby stretching it tightly beneath the muscular contractions. Otherwise, as the antrum closes off, the crisscross folds will be exaggerated, pushed down in a caudal direction and jammed toward the pylorus.

The failure of this stretching mechanism may account for the herniation of prepyloric mucosal folds through the pylorus. On a number of occasions I have observed under the fluoroscope a small polypoid elevation on the mucous membrane slide in a cephalad direction as the antrum closed off under a contraction. The change in the direction of the antral folds does not occur when there are moderately deep contractions but only when a deep constriction takes place by which gastric contents are expelled. Schindler⁶ observed through the gastroscope the formation of radial folds with antral peristalsis.

Whatever may be the mechanism, this movement of the mucous membrane seems to be part of the normal antral physiology. These clinical observations are to be checked by animal experiments.

GASTRITIS AND DISTURBANCES IN MOTILITY

Involvement of the deeper layers of the stomach by inflammation occurs frequently according to all the writers reporting histologic studies of gastritis. The movement of the mucous membrane may be hampered or prevented by infiltration or fibrosis of the muscularis

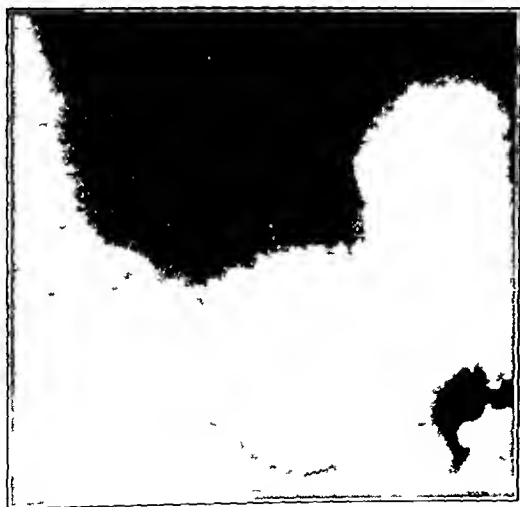

Fig 1 (case 1)—Antral gastritis with hypertrophied mucosal folds and hemorrhage. A doctor aged 49 had digestive symptoms for many years. A severe gastric hemorrhage reduced his hemoglobin content to 50 per cent. The x-ray examination disclosed an asymmetrical defect in the proximal end of the duodenal bulb suggesting a polyp with a heavy fold running through the pylorus and exaggerated folds along the margins of the bulb. At operation no polyp was found. The prepyloric mucosal folds were greatly exaggerated and could be easily pushed through the pylorus. On the edge of one of them was an erosion the size of a pin head, the only demonstrable site from which hemorrhage might have occurred. No duodenal ulcer was present.

mucosae and of the submucosa with adhesion of mucosa to muscle wall. This is apparently the explanation for the failure of the antral folds to flatten under pressure of the hand or of the constricting antral systole and for their herniation through the pylorus instead of retrac-

tion cephalad as gastric contents are expelled. Dwyer¹⁰ noted the failure of the mucous membrane to protrude over the cut edge of the stomach wall in two cases, in which resection was done for hypertrophy of the pyloric muscle.

Edema of the mucosa is frequently noted by the gastroscopists and is often mentioned by the histo-

Fig 2—Change in direction of the mucosal folds with antral systole. A With the antrum relaxed the folds run transversely across the stomach. B With the antral systole the folds become much more slender and run parallel with the long axis of the stomach. Fluoroscopic observations suggest that the mucous membrane moves cephalad under the constriction.

gists. In one instance (case 2, fig 3) edema fluid was observed at operation to run from the cut edge of the stomach, in the microscopic section from the specimen large tissue spaces distended with amorphous pink-staining material were present in the submucosa. The edema and the inflammatory reaction in the submucosa and in the muscularis propria apparently affect the nerve plexuses. Holsti¹⁰ made the only serious attempt at a special study of the nerve elements in the gastric wall which is to be found in the literature. In specimens from patients with severe digestive symptoms but without peptic ulcer, he was able to demonstrate acute inflammatory changes around and within the ganglions, more marked in the myenteric than in Meissner's plexus. According to Alvarez¹¹ there is some evidence that the myenteric plexus is concerned with relaxation, damage to or removal of the plexuses causes a rise in tone sometimes so marked that rhythmic contraction becomes impossible. Thomas, Creder and Mogan¹² found evidence that an inhibitory reflex from the duodenum was routed through the vagus, presumably, therefore, damage to the vagus endings in the gastric wall by inflammation might interfere with the operation of this relaxing reflex.

Whatever may be the exact mechanism, in cases of well marked gastritis in which there can be no doubt about the diagnosis there are three major disturbances in motility. 1 Peristalsis may be very irregular in depth and in timing or may be absent for long periods; the waves seem stiff and fail to develop into antral systoles. 2 Prepyloric narrowing may be present, sometimes relatively slight and amounting merely to a

failure of the region to expand flexibly to the normal width after a contraction, but sometimes so marked that the antrum appears as a narrow channel (case 3, figs 4 and 5). In the narrowed prepyloric region the mucous membrane may be smooth and atrophic, increasing the similarity to annular infiltrating carcinoma or the folds may be exaggerated and even polypoid in appearance. Barium sulfate may be prevented by spasm from approaching the pylorus for some time. Pylorospasm may be present.

As a result of these disturbances the emptying of the stomach may be greatly delayed. A delay may occur in spite of a wide open pylorus. It is often difficult to expel barium sulfate by manual pressure at fluoroscopy.

The prepyloric narrowing is sometimes associated with mucosal erosions demonstrable only by the gastroscope or by the pathologist and sometimes with real penetrating peptic ulcer, usually located in the upper part of the narrowed area or definitely above it. It has been the custom to attribute the antral spasm to the ulcer. As the narrowing may be just as marked

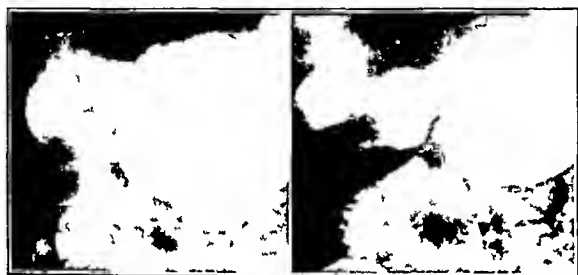

Fig. 3 (case 2)—Antral gastritis with prepyloric spasm. The lower end of the stomach was resected because the pylorus and prepyloric walls were thickened making carcinoma difficult to rule out. Edema fluid was observed to run from the cut edge of the stomach and the wall then became less thick and stiff. The pathologic examination disclosed hypertrophy of the pyloric muscle, a mucosal erosion not visible on the films and histologic evidence of gastritis including marked edema of the submucosa. (Dr. E. P. Pendergrass, University Hospital, Philadelphia, gave permission to use this case.)

without as with an ulcer, it seems more logical to assume that the spasm is the result of the inflammation of the gastric wall, which is present in either case.

GASTRITIS AND HYPERTROPHY OF THE PYLORIC MUSCLE

Cruveilhier¹³ is credited with the first description of hypertrophy of the pyloric muscle. Figure 6 is a reproduction of his beautiful illustration of this condition, which shows the narrowing of the prepyloric region. His description of two cases of benign pyloric obstruction indicates that he was probably dealing with the condition under discussion.

Boas¹⁴ reported two cases in which his positive clinical diagnosis was confirmed at operation. He expressed the opinion that the hypertrophy of the pyloric muscle was the direct result of inflammation and used the term "stenosing gastritis." Serck-Hanussen¹⁵ found gastritis invariably present with hypertrophy of the pyloric muscle and concluded that the demonstration of the latter may be taken as positive evidence of gastritis. In

all of nine specimens of hypertrophied pyloric muscle in the Department of Surgical Pathology of the Presbyterian Hospital, histologic evidence of gastritis was observed (Stout¹⁶). After an analysis of the material from the Institute of Pathology of Berlin University, Rossle¹⁷ concluded that this condition is secondary to inflammation in the pyloric region and is an "activity

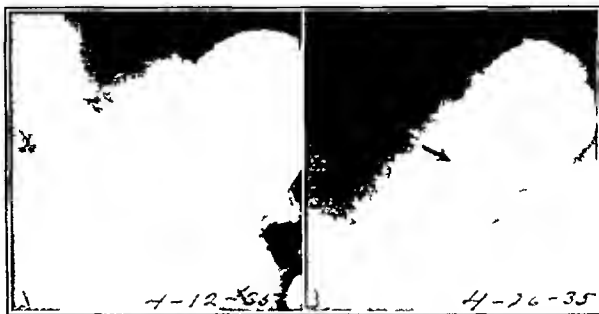

Fig. 4 (case 3)—Antral gastritis with marked spasm and hypertrophy of the pyloric muscle. A man aged 63 with a long history of infections of the respiratory tract and shortness of breath complained of abdominal distention, gas, epigastric pressure and loss of weight for six weeks. A examination elsewhere before admission to the Presbyterian Hospital disclosed persistent narrowing of the antrum which was interpreted as annular carcinoma. B, reexamination after admission disclosed the same narrowing of the antrum. Because small mucosal folds persisted in the narrowed region and because on prolonged observation an occasional moderate expansion was seen, the narrowing was interpreted as due to spasm and not to carcinoma. The arrow points to a shallow ulcer crater not to be seen on the films taken at the previous examination. The patient died of pulmonary insufficiency due to severe bullous emphysema. At autopsy benign hypertrophy of the pyloric muscle was observed (fig. 5). A small shallow mucosal ulcer which did not extend into the submucosa was demonstrated on the lesser curvature.

hypertrophy." He discarded the theory of congenital origin so frequently repeated in the literature, because the condition is observed too frequently in adults (3 per cent in 5,000 necropsies in Berlin and Basel) and practically never in older children.

In a study of 100 specimens of resected stomachs, Ramond and Jacquelin¹⁸ observed thickening of the

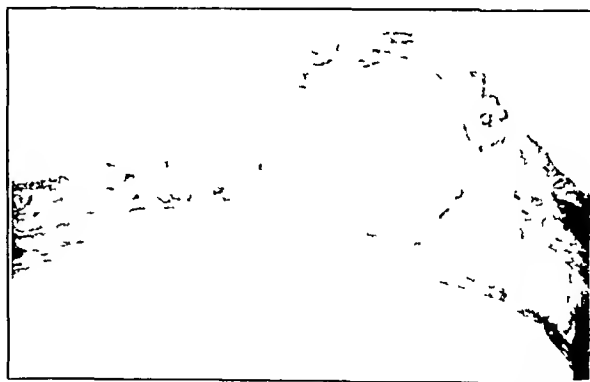

Fig. 5 (case 3)—Section of hypertrophied pyloric muscle under low power. Sections of the anterior wall of the stomach showed evidence of atrophy of the mucosa with fibrosis and marked infiltration of the deeper layers with lymphocytes. The muscularis mucosae was fibrotic and in places almost destroyed. The superficial part showed postmortem autolysis.

muscularis almost always associated with what they called "pyloro-antritis." Konjetzny¹⁹ (1936) stated that hypertrophy of the pyloric muscle results from "gastroduodentitis." According to the reports of many

others (Dwight,⁹ Fitzgerald,¹⁰ Kaufmann,¹¹ Wanke,¹² McNamee²² and Johnston²⁴) this condition, usually with thickening of the prepyloric muscle, seems invariably associated with inflammation. At the present time, therefore, the evidence strongly favors the opinion that gastritis is an important factor in the cause of hypertrophy of the pyloric muscle. In this connection, however, a question might be raised as to the significance of unilateral hypertrophy of the pylorus, which is not infrequently encountered.

The most important x-ray sign of hypertrophy of the pyloric muscle is elongation of the pyloric channel with preservation of the mucosal folds. When prepyloric spasm is also present, as it frequently is, the proximal limits of the channel may not be identified (case 3, fig 4), and the diagnosis may be only suspected.

DIFFERENTIAL DIAGNOSIS

The difficulty encountered by both radiologists and surgeons in differentiating antral gastritis and its complications from carcinoma is attested by numerous writers (Haudek,²⁴ Seick-Hannsen¹⁰ and others).

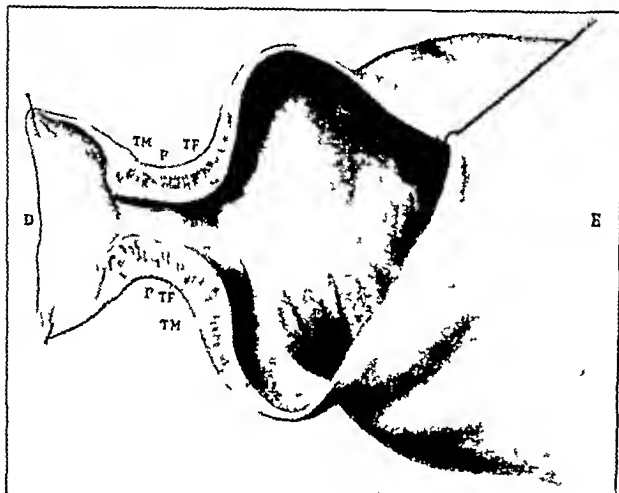

Fig. 6—Cruveilhier's illustration of benign narrowing of the pylorus.

Many gastric resections have been correctly done because the surgeon could not be sure that the palpable thickening of the antral wall was not due to early malignant disease. The difficulty is enhanced for the radiologist by the fact that infiltrating carcinoma does not necessarily obliterate completely contractions of the muscle. Furthermore carcinoma sometimes causes hypertrophy of the muscle.

The most important differential point is the demonstration by pressure methods (Berg¹⁵) or otherwise of mucosal folds in the narrowed area which should be obliterated by infiltrating carcinoma, sometimes these folds run through the pylorus into the duodenum.

However, carcinoma may infiltrate one wall leaving the mucosal folds intact on the other. If atrophic gastritis has caused a thinning of the mucous membrane and an absence of folds, the diagnosis becomes very difficult. Although the antrum or its prepyloric segment may remain persistently narrow, it may occasionally expand sufficiently to make it seem unlikely that an infiltrating lesion is present. A definite palpable mass corresponding under the fluoroscope to the antrum should be considered as evidence in favor of malignant disease.

Some writers advise repetition of the examination after the administration of atropine to physiologic effect, but I have never been much impressed by its efficacy. The importance of gastric lavage in the treatment of gastritis is emphasized by many observers. Boas¹⁴ recommended it in 1898. Repetition of the examination after several days of lavage, particularly if definite stasis is present, has been more helpful according to my experience.

Konjetzny³ (1936) expressed the opinion that demonstration of enlargement of the pyloric muscle should be considered an indication for operation because of the difficulty, even with biopsy of differentiating a benign from a malignant lesion.

SUMMARY

Antral gastritis is associated with a "prepyloric syndrome," as Kaufmann called it. This syndrome consists of (1) prepyloric narrowing of varying degrees due to spasm, (2) abnormal, stiff, irregular peristalsis, (3) sometimes exaggeration and sometimes diminution or absence of mucosal folds, (4) hypertrophy of the pyloric muscle, (5) shallow mucosal erosions which are not demonstrable by x-ray methods, or penetrating ulcer of the lesser curvature, (6) delay in emptying sometimes resulting in a twenty-four hour gastric residue. These signs may not all be present in any one case.

The available evidence suggests that the inflammatory reaction in the gastric wall is directly responsible for these physiologic disturbances and anatomic changes, with the possible exception of the penetrating ulcer. The mural nerve plexuses are apparently concerned in relaxing reflexes. It seems possible that the mechanism of the antral spasm is an effect of edema and inflammation on the ganglions.

The differential diagnosis from carcinoma may be difficult but depends largely on the persistence of mucosal folds in the involved region and, in doubtful cases, on repeated examination after treatment with relaxation of the prepyloric spasm. If doubt persists operation is advisable.

Protection Demanded Against Noise—There has gradually developed in Great Britain a public consciousness of the insidious growth of the social evil of needless noise—a pernicious by-product attributable in great part to an increasing mechanized civilization. With this growing realization the nation is beginning to demand and to receive protection against the nuisance of outrageous noise whether generated by private or public bodies. It is looking for ways and means of mitigating excessive transport noises, particularly on the road and in the air and it is seeking to know why in modern houses and flats it should not be accorded adequate privacy against the natural, though sometimes unreasonable, noises of neighbors. Kave, G. W. C. *Noise and the Nation*. *Nature*, Sept. 11, 1937, p. 446.

SIMPLIFIED TECHNIC OF ONLAY GRAFTS

FOR ALL UNUNITED FRACTURES IN
ACCEPTABLE POSITION

HENRY N HARKINS MD
AND
DALLAS B PHEMISTER MD
CHICAGO

Autogenous bone grafts have come to be generally employed in the treatment of ununited fractures with the exception of those of the neck of the femur and carpal navicular, where other methods are not infrequently used. In case of an ununited fracture of the shaft the grafted material may be made to serve as internal fixation apparatus, supplementary bone, osteogenic substance and stimulant to osteogenesis in those parts of the bone fragments which come in contact with it. Analysis of cases reveals that there is considerable variation in the necessity for any one of these functions according to the case at hand. Thus if the fragments are little atrophied and no bone has been lost there will be less necessity for supplementary bone than if atrophy is marked and if portions of cortex have been lost. Also if the cause of the nonunion is wide separation of fragments there will be less necessity for osteogenesis from the transplant than if there is nonunion with the fragments in good apposition because of failure of osteogenesis. And by the same criterion if the fragments are in good apposition and alignment there will be less necessity for the graft as an internal fixation apparatus than as an osteogenic agent and possibly as supplementary bone.

Hence the technic of bone grafting for ununited fracture cannot well be standardized to one procedure and should be varied somewhat according to the anatomic and physiologic conditions that are present. It should always be made as simple as is compatible with the necessities of the case.

If there is displacement and overriding or if there is loss of substance reduction may necessitate freeing the fragments completely of soft parts for a variable distance back from the fracture line and resection of one or both ends may be necessary to obtain adequate contact. In such cases a graft should be used to fix the fragments in the corrected position. As a rule a relatively strong whole thickness onlay graft best serves the purpose. It may be anchored to the fragments by encircling ties of aluminum bronze or silver wire¹ by heavy catgut or kangaroo tendon or by screws made of beef bone or autogenous grafts according to the technic so well worked out by Henderson-Campbell and others.⁴ In addition, cancellous or osteoperiosteal grafts are placed along the fractured line or in defects of the cortex to assist in osteogenesis and in some cases to serve as supplementary bone.

On the whole the results of this type of operation have been very satisfactory. It is however a relatively extensive procedure and consequently carries some risk of infection and in case of large bones especially the femur, of hemorrhage and shock. The lengthy denudation of fragment ends undoubtedly devitalizes some of the bone at times but this seldom interferes with union. Dead sterile bone has been encountered a few times at operation for nonunion where at a previous operation the ends were extensively denuded as in case 6 of this series. In one case of fractured femur 1½ inches of the end of the upper fragment was gray and bloodless five months after denudation and microscopic examination of the resected portion showed it to have undergone aseptic necrosis. This was no doubt a factor in the causation of nonunion. Resection of fragment ends sometimes shortens the bone to an objectionable extent. The introduction of foreign substances such as beet bone, kangaroo tendon and wire for anchorage of the graft increases slightly the risk of infection. Also in

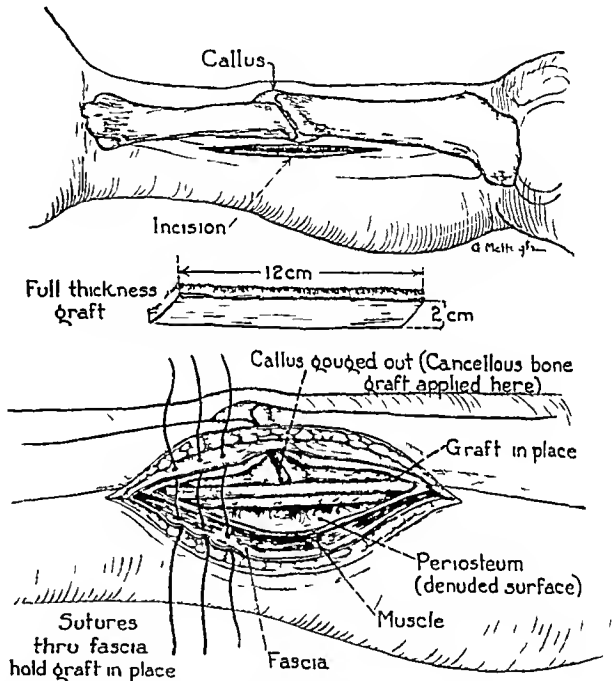

Fig 1—Technic for simplified onlay bone graft procedure. Above is shown an ununited fracture of the tibia as in case 1. Beneath this is an enlarged view of the bone graft and below its insertion.

the case of small bones and of extremely atrophic large bones in children the technical difficulty makes it inadvisable to attempt fixation with screws.

To lessen these risks a simpler operation has been used in cases of nonunion in which displacement is not marked and the position of fragments is such that if union were present the result would be acceptable. The bone of the fracture site is laid bare only on one side leaving the attachments on the other side to help maintain position. Cancellous and whole thickness onlay grafts are applied and held in place by suturing the soft parts about them. The grafts set up osteogenesis and serve as supplementary bone but do not immediately fix the fragments to any appreciable extent. The use of the method in a small number of cases has previously been reported. The success of the procedure

36

is based largely on the fact that if a large onlay graft is applied across the fracture line in good contact union takes place between it and the fragment ends and then the intermediary callus ossifies, whether it is old or new.

The technic of the procedure is as follows:

1 The fracture is exposed through a 12 to 16 cm incision and the periosteum incised and reflected from about one half of the circumference of either fragment for an average length of from 5 to 7 cm.

2 An even surface is created for the reception of grafts by chiseling away any protruding callus or displaced cortex.

3 The intermediary callus is usually gouged or curetted out of the fracture line in most of its extent. While union occurred in all of the fourteen cases when this callus was left in, still it is considered best to remove it when feasible, as a newly formed callus should ossify more readily than an old one. The fragments are angulated somewhat to assist in the process, care being taken not to detach the bridge of callus and soft parts on the opposite side, which might permit of displacement. The bony callus closing the ends of the marrow cavity is not removed, as this has been found unnecessary. Any preexisting angulation can usually then be corrected.

4 One or sometimes two appropriately dimensioned whole thickness and several cancellous bone grafts are applied to the prepared surface and along the fracture line as indicated in figure 1. The grafts are taken usually from the healthy tibia, but in some instances from the longer end of the fractured bone or rarely from other bones. Endosteal surface is nearly always placed next to cortex of fragments and may be trimmed to fit. In case the graft is turned over in order to obtain a more accurate fit, its periosteum is stripped off

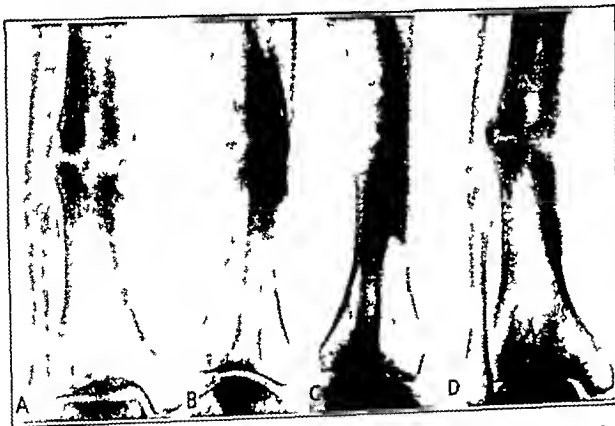

Fig 2 (case 1)—Preoperative view and results at intervals after insertion of onlay graft in ununited fracture of tibia. A before operation. B six weeks after operation. C and D five months after operation.

5 The grafts are held snugly in place in contact with the fragments by suturing the soft parts over them with interrupted sutures of 0 chromic catgut passing through the deep fascia. The subcutaneous tissues and skin are also closed with interrupted sutures.

6 A plaster-of-paris cast is applied and left on for from two to three months depending on the case.

If there is infection with osteomyelitis as a result of compounding or of previous operation, it is first neces-

sary to remove any dead bone and obtain wound healing. In most cases it is then advisable to wait from three to six months, depending on the severity and duration of the old infection, before operation for the nonunion. But, in case of infected fractures of the tibia when the wound is anterior and of long standing and the posterior part of the fracture either has

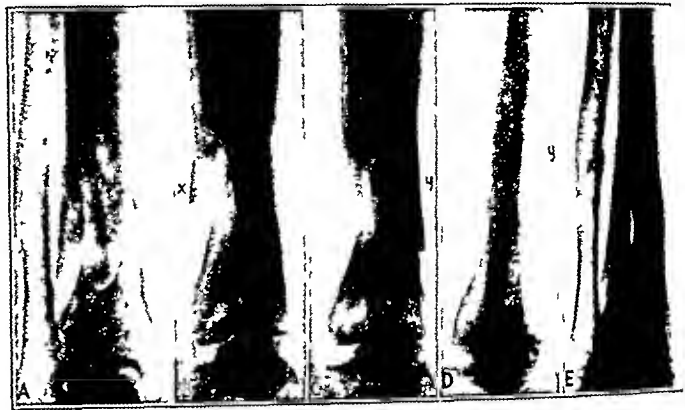

Fig 3 (case 2)—Preoperative view and results at intervals after insertion of onlay graft in ununited fracture of tibia. A and B before operation. C twelve weeks after operation. D and E twenty-two months after operation. X shows dead bone. Y shows transplanted bone.

been infected or has been free from infection for some time, a modified operation may be performed soon after closure of the anterior wound. It consists in exposure of the posterior surface of the tibia at the fracture level through a posteromesial incision as nearly opposite the old wound as possible and insertion of a heavy whole thickness bone graft about 10 cm in length, leaving the intermediary callus intact except where an elevation must be leveled off for contacting the graft. If the recent field of infection is avoided, it is possible to insert a bone graft without infection and secure bony union weeks or months before it would be safe to open the whole fracture field, freshen the fragment ends and tie or screw on a whole thickness graft. But the incidence of infection among the cases to be reported was greater in this small group than in the large group that was either never infected or had been healed for months, so that care must be exercised in the selection of cases and in restricting the operative procedure.

ANALYSIS OF CASES

Among the ninety-three cases of ununited fracture of the shaft of bone operated on in the University of Chicago Clinics during the past eight years, this procedure was employed in thirty-nine, or 42 per cent. Twenty-six of the thirty-nine patients were males and thirteen were females. Thirty-six were adults and three were children, two of whom had congenital pseudarthrosis of the tibia. The age of the patients ranged from 2 to 62 years, the average being 35 years. Eleven cases were due to automobile accidents, a similar number to falls, three to gunshot wounds and the rest to other causes. Most patients received immediate treatment elsewhere. In twelve cases there is a record of the fracture being compound and in ten cases infection was noted. Previous operation for nonunion had been performed in three cases. Of the thirty-nine cases of operation for a total of forty-two fractures, bony union followed in thirty-eight. The one failure was the result of a technical error, and a second onlay operation resulted in bony union. In six recently healed cases of infection of fractures of the tibia operation was

done by early insertion of the graft on the side opposite the old wound, with mild recurrence of the infection in two but with union of the fracture in all instances.

The distribution of the fractures in the skeleton is shown in the accompanying table.

USE OF THE OPERATION FOR FRACTURES OF VARIOUS BONES

Tibia—Ununited fracture of this bone was the one for which the operation was most frequently performed (fifteen times). It was also the fracture that before operation had been most frequently infected (eight times), that after operation in three cases became infected and that was the seat of the one nonunion. In one case of infection the whole thickness graft that became attached, although there was partial necrosis, was removed after the fracture united. In one instance both tibias were ununited and were united after grafting. In another case there was refracture three years later with nonunion, which again healed after grafting.

CASE 1—L. P., a man, aged 25 illustrates the successful use of the method in a case in which a compound fracture of one year standing had been treated early with a steel plate resulting in slight infection and nonunion. The plate was removed six months before and some dead bone five months before. The wound had been healed for four months. A whole thickness graft from the other tibia was applied postero-medially and an osteoperiosteal graft on either side of it at the fracture line after some of the adjacent intermediary callus had been removed. There was primary healing of the wound. Figure 2 *A* and *B* shows the roentgenographic appearance before and six weeks after operation and *C* and *D* the healing five months after operation. Note the ossification of the old intermediary callus anteriorly in *C*, which was not disturbed at operation.

Case 2 illustrates the successful use of the method following infection and sequestrectomy when the graft

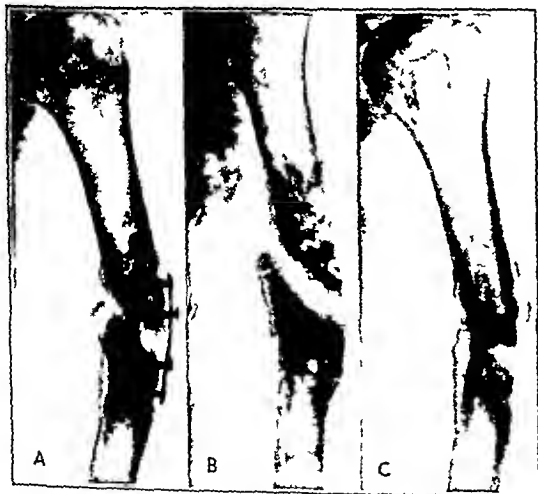

Fig 4 (case 3)—Preoperative view and results at intervals after insertion of onlay graft in ununited fracture of humerus. *A* before operation. *B* one week after operation. *C* ten months after operation.

was inserted posteriorly before the anterior sinus was healed.

CASE 2—H. C., a man aged 45, was admitted July 31, 1932 with an infected and ununited compound fracture of the lower third of the tibia of four months standing (fig 3 *A* and *B*). Two cm. of the anterior cortex of the upper fragment was dead and partly sequestered and one month later it was removed through the anterior wound. Five weeks later when the wound had become very small but was not yet healed the

posterior surface of the tibia was laid bare through a postero-medial incision and an onlay graft was applied and held in place by suturing the soft parts. Intermediary callus was not disturbed. Three months later the fracture was healed. A small sinus persisted anteriorly for some time but walking was resumed gradually and the patient returned to work. Figure 3 shows the result (*C*) twelve weeks and (*D* and *E*) twenty-two months after operation.

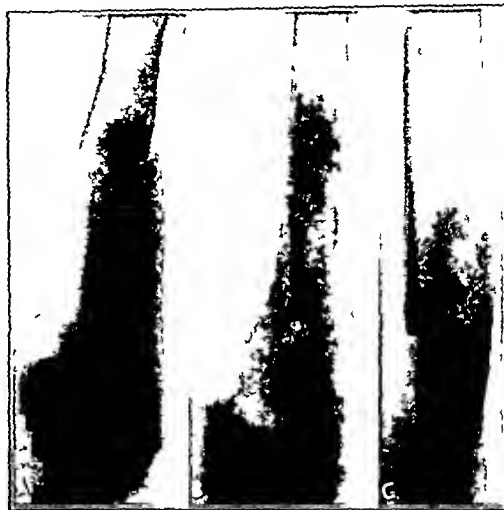

Fig 5 (case 4)—*A*, preoperative view and *B* and *C* result six months after insertion of onlay graft in ununited fracture of humerus.

One fracture of the upper end of the tibia failed to unite as a result of the use of two short grafts that were applied without adequate leveling of surfaces, so that they were not in contact with the lower fragment.

Humerus—The ends of the fragments are usually in contact, and angulation if present can usually be corrected after removal of intermediary callus, so that this procedure is relatively often applicable to the

Distribution of Thirty-Nine Cases of Ununited Fracture Treated by Simplified Onlay Graft

Bone Involved	Number of Cases	Union After First Operation	Union After Second Operation
1 Tibia	15	14	1
2 Humerus	8	8	
3 Forearm	8	8	
Radius	(2)	(2)	
Ulna	(3)	(3)	
Radius and ulna	(3)	(3)	
4 Mandible	3	3	
5 Shaft of femur	2	2	
6 Clavicle	2	2	
7 Ilium	1	1

humerus. All eight cases remained clean and union occurred promptly after one operation. In the lower half the incision should be along the course of the radial nerve and the graft should usually be inserted anterior and mesial to it. Near the elbow the graft should not be too thick, as it may interfere with motion. Cases 3 and 4 are illustrative.

CASE 3—B. C., a man aged 35, fractured the left humerus fourteen months before admission. Nonunion persisted after a clean metal plating operation four months after the injury. The fracture site was exposed, the screws and plates were removed, the intermediary callus was gouged out and two tibial whole thickness and several cancellous grafts were inserted and the soft parts sutured. The body and arm were

in a cast for ten weeks, resulting in bony union. Figure 4 shows the condition (A) before, (B) one week and (C) ten months after operation.

CASE 4—J. R., a man, aged 59, fractured the left humerus ten months before admission. Open reduction and metal plating one week after injury was followed by nonunion. The plate was removed after four months. The arm had been immobilized since and there was marked stiffness and bone

Fig. 6 (case 5)—A, preoperative view and B and C, result twelve weeks after insertion of onlay graft in ununited fracture of ulna.

atrophy. Through an anterolateral incision the fracture was exposed, the callus gouged out anteriorly and a whole thickness tibial graft applied in front with cancellous grafts at the fracture line. Union occurred during ten weeks of immobilization in a body and arm cast. Figure 5 shows the condition (A) before and (B and C) six months after operation.

This was an ideal case for use of the procedure, since the apposition and alignment were excellent and there was no surface irregularity to be chiseled off.

Bones of the Forearm—The method is well suited to nonunion of the shaft of the radius or ulna separately, as the fragments are often in good position but not so for nonunion of the two bones at the same level. In the latter group the fragments are likely to be displaced and angulated and the two bones approximated. Bony union followed operation promptly in the three cases in which both bones were ununited, but two cases were wrongly selected with bones too nearly approximated and an interosseous bony bridge formed which later had to be excised. Complete freeing of fragments with alignment and fixation by grafts tied or screwed to fragments is indicated in such cases as in that way the bones are kept apart.

Case 5 shows the simplicity of the procedure when applied to the ulna.

CASE 5—S. M., a man, aged 29, fractured both bones of the forearm ten months before admission. The ulna was cut down on a week later and the fracture ends were tied with catgut, but nonunion followed although the displaced radial fragments which were not exposed united. At operation ten months after injury the posterior surface of fragments was bared, intermediary callus was gouged out, cancellous and whole thickness onlay grafts were applied and soft parts were closed over them. Bony union took place during eight weeks of immobilization in a cast. Figure 6 shows the lesion (A) ten months after injury and (B and C) twelve weeks after operation.

That the operation is suitable for more complicated situations is illustrated by the following case.

CASE 6—C. Z., aged 37 years, fractured the ulna and located the head of the radius two and a half years before admission. Three months after injury the radial head was removed and the ulnar fragments were fixed by means of an ivory peg. Nonunion persisted, and nine months later a tibial bone graft was applied and fixed with ivory screws. This failing, seven months later the fragments were anchored together with wires, but nonunion persisted. At operation the back of the ulna was exposed and the wires were removed. An area of dead bone was found at the end of the proximal fragment. Intermediary callus was curetted out, a heavy whole thickness tibial graft was applied, the wound was closed and the arm and forearm were immobilized in a cast. Bony union resulted after eleven weeks. Figure 7 shows the conditions present (A) on admission and (B) six months after operation.

Grafts for use in the radius and ulna should not be too bulky and should be cut from the upper end of the tibia where the cortex is thin.

Mandible—The operation is better suited to the mandible than any other procedure, since anchorage of a graft with ties or screws is much more complicated. Through an incision along its lower border, the medial surface of the mandible is bared and the graft applied. In two cases intermediary callus was removed and in one it was not disturbed. The graft from the thin upper cortex of the tibia is held snugly in place by the sutured soft parts. The upper and lower teeth are wired together for from six to eight weeks. Defects of the mandible have also been repaired by applying two whole thickness grafts in a similar way.

Femur—Ununited fractures of the femur rarely lend themselves to this procedure since displacement, overriding and angulation usually call for reduction and utilization of graft as an internal fixation apparatus. In the two suitable cases it worked out well, one being a transverse fracture, previously reported, in which none of the intermediary callus was removed.

Clavicle—The whole thickness graft should again be thin and the surfaces flattened to give good contact in order not to create a permanent bony enlargement.

Fractures of the ischium or other parts of the innominate bone very rarely fail to unite. The one case in this series was a part of the picture of multiple fractures of the pelvis four months previously and the fragments were widely separated. Three tibial grafts were onlaid and bony union resulted.

Fig. 7 (case 6)—A, preoperative view and B, result six months after insertion of onlay graft in ununited fracture of ulna.

SUMMARY AND CONCLUSIONS

Ununited fracture with the fragments in acceptable position has been caused to unite in thirty-eight of thirty-nine patients at the first attempt, and in the one case of failure at the second attempt, by exposure of fragments on one side and the application of whole thickness and cancellous bone grafts, which were held in place by the overlying soft parts sutured about them. The intermediary callus may or may not be gouged out according to the case but union occurred in all fourteen cases in which it was left in. The attached soft parts on the opposite side serve to return the position of fragments and displacement did not occur subsequently within the plaster cast. The operation is shorter and simpler than that in which fragment ends are freed, aligned and fixed by a graft tied or screwed to them. The results demonstrate that it is unnecessary to remove the new bone closing the medullary cavity of the ends of the fragments. In selected cases of infected fractures of the tibia with nonunion, operation has been successfully done soon after healing by incising and implanting the graft in contact with the fragments through a clean field on the side opposite the scar, thereby saving much time. But infection did recur in two cases, so that they should be selected with care.

950 East Fifty-Ninth Street

ABSTRACT OF DISCUSSION

DR WILLIS C CAMPBELL, Memphis, Tenn. The merits of any treatment must be estimated by the percentage of end results obtained. I have no doubt that by many operative procedures as the employment of chip grafts, union can be secured in a certain proportion of cases but the procedure that will secure union in the highest percentage is the one that warrants attention. I believe in the onlay graft and have been an exponent of that graft. There are two factors that are essential to obtaining union: first absolute fixation, second promotion of osteogenesis by the use of autogenous bone. This is best accomplished by a full thickness cortical graft pegged in place by autogenous nails supplemented by spongy bone packed around the ends of the fragments. Firm fixation is thus secured plus the introduction of autogenous material capable of osteogenesis. It is necessary to distinguish in all cases between delayed union and nonunion. In delayed union one can often secure good results by conservative measures even by drilling holes in fragments but in nonunion of long standing the problem is more difficult. When a Lane plate is applied simple removal of the plate is frequently quite sufficient to induce union as the plate itself may be causing the nonunion. I prefer to delay operative procedures for some time after removal of the plate to see what will happen before I employ any type of bone graft. This simple graft may be an excellent measure to use in this type of case. The question also arises as to the length of time in which union is to be secured. I find that after absolute fixation which is secured at the time of the operation union is obtained more rapidly and that apparatus can be dispensed with at a much earlier date than by less efficient methods. In fact in one case of fracture of the bones of the forearm the patient left the hospital within twenty-four hours and took off his cast at the end of three or four weeks but he obtained an excellent union with a perfect result. That of course was unusual. However I feel from my own experience in using all types of grafts that to produce osteogenesis alone is not sufficient. I did not have the same percentage of good results in a large number of cases that I am now able to secure by conforming to the two principles of absolute fixation and the promotion of osteogenesis by autogenous grafts and the use of spongy bone.

DR W. K. WEST, Oklahoma City. While I have had no experience with the authors' method as described in this paper

it seems to me that it would be better to obtain stability as well as osteogenesis at the time the operative technic is carried out. However, it must be borne in mind that the pegging technic is not easy and is impossible unless adequate equipment and assistance is available. Therefore I can see that there would be circumstances in which the technic described would be the one of choice. For reasons of comparison, I wish to illustrate a few cases of nonunion in which the Campbell method of onlay graft was used when there was no callus formation or when there was marked defect in the bone continuity also to illustrate a second method in cases in which there was an attempt at union but for some reason, the fracture did not unite solidly. The Campbell technic consists in using autogenous bone pegs in connection with massive onlay grafts. The advantage of this method over any bone graft procedure in which osteogenesis is paramount is that one not only obtains fresh bone for healing of the fracture but at the same time maintains a very rigid stability. The second method is far simpler than the Campbell method or the method described by Drs Harkins and Phemister. A simple sliding onlay graft is used maintained by two small stainless steel wires which are easily removed with the use of a local anesthetic after union takes place. The sliding graft is especially indicated in cases in which apposition of the bone fragments is satisfactory or callus formation has begun. Good results can be expected by using this method thereby avoiding the necessity of going into the tibia for the graft. From a medico-legal standpoint it is important to know that additional compensation is applied for in many industrial cases owing to the fact that there is a permanent scar on the leg resulting from removal of the bone graft.

DR MELVIN S. HENDERSON, Rochester, Minn. The technic of bone grafting is not standardized and properly never should be completely standardized. The particular method that is to be used must fit the case and not the case fit the method. No doubt certain types of ununited fracture can be quite conveniently treated by the method advanced by Drs Harkins and Phemister. However, I think that if it were used in a routine manner in a large series of cases it would be found that there would be a fair proportion of failures. The authors have told us that it is not to be used in a routine manner. There are certain essential points about bone grafting that are definitely pertinent to this discussion. The technic displayed in the exhibit by my associates and myself in the orthopedic section is based on an experience over a long term of years in dealing with 591 patients with ununited fractures in whom over 600 bone grafting operations were performed. We have evolved a certain technic which we are using today and which is giving us better results than we have obtained in the past. The points we might call essential are (1) that the graft must be 'massive' using the term massive to emphasize that the graft must be large. Willis Campbell has coined the word onlay. I think the two might be combined and that it might be called the massive onlay graft. Secondly, the very important factor in obtaining union in these obstinate cases is the use of small pieces of cancellous bone packing them about the fracture line and the line of contact of the graft with the fragments. I learned this from Willis Campbell's bone block operation wherein he showed that a pile of small cancellous bone chips placed on the os calcis just in front of the insertion of the Achilles tendon would lead to the formation of a column of bone that would furnish the block and prevent foot drop in paralytic flail feet. Thirdly, the fracture itself should be exposed, the eburnated bone ends removed and the medullary cavities in each fragment opened up. Fourthly, the graft should be held firmly to the fragments by some form of internal fixation either autogenous pegs or beef-bone screws or in certain difficult cases by metal bands or metal screws. Fifthly, external fixation must be provided also. If one does not use external fixation in the way of properly applied plaster-of-paris casts one courts disaster. The reason for this is that there comes a weak period in the growing and healing period of a fracture and graft usually at about the end of the sixth or seventh week. The graft is weakened by some absorption and

enough new bone has not as yet formed to give strength. If external fixation is inadequate at that time, the graft will in all probability break.

DR ELVEN J BERKHEISER, Chicago. In the June issue of *Surgery, Gynecology and Obstetrics* I reported several cases of nonunion of the clavicle in which I employed the same technic and obtained bony union not only in the cases in which the position of the fragments was acceptable but also in the cases in which the position was not acceptable in that the inner end of the outer fragment had to be freed and elevated because of its pressure on the brachial plexus, and in a third group in which there was loss of substance of the bone with a gap of more than 2 inches between the ends of the fragments. In fractures of the tibia with nonunion I prefer and have used a more simple technic than that demonstrated by Dr Jepson at the Academy of Orthopedic Surgery. It has been used and bony union has been obtained in about twenty cases. This procedure has failed in a case of congenital pseudarthrosis in which operation was performed when the patient was too young. The simplified procedure consists of exposure of the tibia over the medial aspect, cutting the reversible graft longer in one fragment than the other with a single circular saw so inclined that the graft shall be wedged or in keystone shape in cross section. This graft consists of all layers—endosteum, medullary, cortex, cambium and periosteal layers. I am prejudiced in favor of the use of the attached periosteum, although there is some difference of opinion about this point. Then the graft is reversed and driven in or countersunk. In doing this the receiving fragments are sprung outward and grasp the graft, holding it securely in position.

DR EDWIN W RYERSON, Chicago. The difference between this operation and most of the other operations for ununited fractures is that it does not attempt to fix firmly the graft, and it is perfectly evident, from the thirty-nine cases that were shown, that one does not have to secure absolute immobilization. Therefore the Harkins-Phemister method resolves itself into one of stimulation of osteogenesis. I don't say osteogenesis, because in the Bible we say Genesis, Exodus, Leviticus and so on. There are certain fractures which need only some new bone as an osteogenic stimulus. There are other fractures which need more than that, and I think it is a pretty good principle when one is operating on an ununited fracture to secure just as much immobilization by the transplant as one can. On the other hand, to use the bone screws whether beef bone or autogenous bone screws, is a much more difficult operation to perform and involves a little more risk to the patient from shock, so if one thinks one has a case in which simply some osteogenic bone needs to be applied one should use this simple method. If there is no way of deciding, possibly, which way one ought to think the fixation method should be used.

DR DALLAS B PHEMISTER, Chicago. The procedure was used in only 42 per cent of the cases of ununited fracture of the shaft so that no attempt has been made to apply it to unsuitable cases. In the ordinary case of ununited fracture, the intermediary callus is unossified and the ends of the marrow canal of the fragments are closed by a layer of new bone. It is usually considered necessary to get rid of the intermediary callus and the bone closing the fragment ends before the application of the bone graft. Our experience with these thirty-nine cases has shown that if a long heavy whole thickness graft is placed to bridge the fracture line and spongy grafts are applied at the fracture site, union of the fracture will follow whether or not the intermediary callus and bone closing the ends of the medullary canal are removed. It also shows that it is not necessary to fasten the heavy graft to the fragment ends if they are held together by soft parts on the side opposite the graft. The sutured soft parts hold it in place. Osteogenesis takes place from the ends of the fragments and from the graft where they come in contact as well as from the cancellous grafts, and bony union follows between graft and fragments. Accompanying this there is ossification of the intermediary callus. If this procedure is followed advisedly, nearly one half of the patients with ununited fracture of the shaft will be spared a more extensive operation.

EXOPHTHALMOS COMPLICATING IRRADIATION

LEROY A SCHALL, MD
BOSTON

In the discussion of Dr Frederick T Hill's paper "The Management of Malignant Disease in a Small Hospital," read before the Eastern Section of the American Laryngological, Rhinological and Otolaryngological Society last January, Dr Perry G Goldsmith reported a case of malignant nasal sinus disease in which exophthalmos developed after irradiation. In this discussion, Dr Goldsmith emphasized our lack of knowledge concerning the pathology, the course and the prognosis of exophthalmos occurring as a result of irradiation.

The literature is indeed scanty. Although Newman in 1926 reported the loss of eleven eyes in ninety-seven cases of malignant disease of the nasal sinuses, he did not specifically say that they were lost as the result of destructive changes secondary to irradiation. Ohngren

Fig 1—Three vessels are present in the midportion of this section. The artery centrally shows almost complete obliteration of its lumen with marked hyaline thickening of the fibrous tissue of its wall. There is slight lymphocytic infiltration. Note the degeneration of the elastica. On each side are venae comites that to the left showing a change similar to the change in the artery that to the right showing an irregular outline of its wall and its lumen only slightly narrowed still containing red cells. Note the hyalinization of the collagen the diffuse staining property giving a rather fuzzy appearance. Hyaline fibroblasts and lymphocytes are scattered through the tissue. Just beneath the artery is a moderate-sized telangiectatic vessel filled with red cells.

discussed injuries to the eye following his combined electrosurgical operation, both with and without irradiation, and he attempted to classify these injuries into two groups: first, those which were due to excessive heat generated at the time of the operation, and second, changes in the eye that appear late, as the result of infection.

This paper is based on five cases in which exophthalmos developed as a result of the treatment of malignant disease of the nasal sinuses. In three of these cases the condition occurred after operation and irradiation. In two it followed irradiation without operation.

Read before the Section on Laryngology, Otolaryngology and Rhinology at the Eighty-Eighth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1937.
1. New, Gordon B. Malignant Tumors of the Antrum of the Maxillary Sinus. *Arch. Otolaryng.* 4: 201 (Sept.) 1926.
2. Ohngren, I. George. Malignant Tumors of the Maxillary Sinus. *Region Acta oto-laryng. supp.* 19, 1933.

In the treatment of malignant tumors of the nasal sinuses I have followed the reasoning of Barnes,³ and his words are worthy of repetition. He wrote:

It is obvious that the first principles of the operative treatment of malignant disease are violated when a tumor is removed, not only without a fair margin of normal tissue but also by a crushing operation which amounts to a curettage. No better method could possibly be imagined for producing local implan-

Fig 2—Radiation reaction in the orbit. In the center of the section is an arteriole completely obliterated by a hyaline thickening of the connective tissue elements of its wall. There is slight proliferation of the endothelium. Much of the connective tissue is hyalinized. Some of the fibroblasts are swollen and distorted. There is a rather diffuse lymphocytic infiltration.

tations and setting up distant metastases. Yet, on account of the bony surroundings of the tumors, which separate them from the brain and from the eye, no other course is open, except in case of antral involvement only. It is for this reason that immediate postoperative radiation is used.

IRRADIATION

Postoperative irradiation has consisted of platinum tubes of radon of a strength of approximately 100 mg placed in the center of the gauze packing at the close

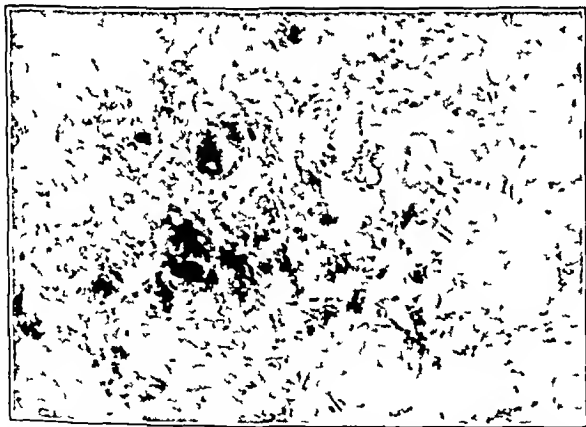

Fig 3—The right hand portion of the section shows marked hyalinization of the connective tissue, relatively acellular, and one or two small telangiectatic vessels. The left hand portion shows similar hyalinization of the collagen and a heavier lymphocytic infiltration, the cells being somewhat thickened. The vessels are dilated containing red cells.

of the operation. This packing gives an additional screening of at least 15 cm of gauze. The radium is left in place for a total dose of from 2,000 to 4,000 mg hours. This is the method advocated by Barnes. Recently I have increased the screening by the addi-

tion of 1 mm of lead. In two patients exophthalmos developed even with this additional protection.

For patients with inoperable disease of the sinuses I have, at times, tried interstitial irradiation. By patients with inoperable disease I mean those whose physical condition will not stand operation and whose malignant growth has broken beyond the confines of the sinuses. The interstitial irradiation is given by means of radon in platinum needles of a wall thickness of 0.5 mm and totaling about 100 mg. The needles are inserted into the tumor through a stab incision of the buccal mucosa of the canine fossae and are left in place for a total dose of from 2,000 to 3,000 mg hours. In two patients exophthalmos developed after this method of treatment.

SYMPTOMS AND COURSE

Following irradiation, exophthalmos may occur early, even within the first twenty-four hours, or it may be delayed, coming on weeks after treatment. As the protrusion of the eyes develops there is conjunctival chemosis at first, excessive lacrimation, then exposure

Fig 4—Transitional cell carcinoma involving the left ethmoid and antrum. A modified Moore incision was made and exenteration of the tumor done with electrocoagulation. Radiation consisted of 4 platinum needles totaling 75 mg of radium. Protection consisted of 1 mm of lead and 1 cm of gauze. Exophthalmos developed within twelve hours so that their irradiation was terminated at 2,000 mg hours. Vision and the cornea remained good and the exophthalmos gradually subsided in five months.

and drying of the cornea. Orbital pain is constant and severe. The vision may remain good. With each case the problem of orbital extension of malignant disease must be weighed. As long as the cornea remains healthy, as long as there are normal vision and no limitation of ocular movements, conservative treatment should be employed. When degenerative changes have taken place, such as corneal ulceration and infection, loss of vision or limitation of ocular movements, orbital exenteration is necessary. It is necessary not only to relieve the pain but to eliminate the possibility of orbital extension of the malignant disease.

PATHOLOGY

The effects of irradiation on tissues have been studied by many pathologists, but the work of Wollbach⁴ on the skin remains classic. I have been unable to find

³ Barnes, Harry A. Malignant Tumors of the Nasal Sinuses. Arch Otolaryng 6: 123 (Aug) 1927.

⁴ Wollbach, S. B. Pathological Histology of Chronic N. Rav. Derm. 21: 415 1909.

a previous study of the pathologic changes in exophthalmos following irradiation. I expected them to be the changes of edema and hypertrophy of connective tissue.

From study of the sections removed at four exenterations the pathologic changes due to irradiation on these structures may be described as those due to (1) the effect on the cells, (2) that on the intercellular substance and (3) that on the blood vessels.

In the resting cell the early effect of irradiation is swelling of the cell due to intercellular edema. Vacuoles then appear in the cell protoplasm. If the reaction is prolonged there is degeneration of the mitochondria and of the resting nucleus. If the cell is a secretory cell, degeneration of the Golgi apparatus may take place. In the actively dividing cell, irradiation may arrest mitosis during the early prophase stage. If the division has progressed beyond prophase the mitosis usually goes on to completion. The chromosomes may show varying degrees of degeneration.

Irradiation affects the intercellular substances by causing degeneration of the elastic fibers and by swelling or necrosis of the collagen. The late or delayed reaction may be hyalinization of the collagen or delayed necrosis of the collagen.

The effects on the vessels are both immediate and late. The endothelium of the vessel walls becomes

due to (1) degeneration of the cement substance, (2) degeneration of the Rouget cells or (3) occlusion changes in the deeper veins due to back pressure.

CONCLUSIONS

1 Exophthalmos may result from irradiation by accepted methods. It may come on within twenty-four hours or its appearance may be delayed.

Fig 6—Epidermoid carcinoma, grade 3 of the left antrum and ethmoid breaking through the front face of the antrum. The patient is in poor physical condition. Interstitial irradiation 2,000 mg. hours was given. Exophthalmos developed four weeks after treatment, requiring orbital exenteration due to limitation of motion and pus in the anterior chamber.

Fig 5—Lymphoblastoma of the antrum and ethmoid which had broken through the front face of the antrum. Interstitial irradiation of 4,000 mg. hours was done. Three months later edema of the eyelid began and in two weeks it had progressed to definite exophthalmos with limitation of ocular movements in all directions. There was no tumor involvement of the orbit.

degenerated and produces varying degrees of thrombosis. The late effects are fibrosis of the vessel wall with proliferation of the injured endothelium, which may lead to gradual occlusion of the vessel. Telangiectasis may occur in varying degrees and may be

- 2 Pain is constant and severe.
- 3 As long as degenerative changes in the eyes do not take place conservative measures may be adopted.
- 4 Operative measures to protect the eye have been of little value.
- 5 With degenerative changes in the eyes orbital exenteration is necessary not only to relieve the pain but to eliminate the possibility of orbital extension of the malignant disease.
- 6 The pathologic process is essentially that of degeneration and vessel thrombosis.

270 Commonwealth Avenue

ABSTRACT OF DISCUSSION

DR. ALGERNON B. REFSE, New York. Dr. Schall states that some of his cases of exophthalmos appeared within twenty-four hours after irradiation while others appeared within five to six weeks. Although I have not observed this immediate exophthalmos following irradiation a possible explanation seems to be that the irradiation caused necrosis of the tumor and the toxic effect of this produced an inflammatory reaction in the adjacent loose vascular tissue of the orbit. The cause of exophthalmos that Dr. Schall observed from my case

weeks after irradiation must represent an extension of the new growth into the orbit or, possibly in rare instances, an infection, particularly in cases in which the antrum is the seat of the lesion. In the Head and Neck Clinic of the Memorial Hospital in the past five years I have observed eleven cases of exophthalmos complicating cancer of the nasal sinuses and thirteen cases complicating cancer of the nasopharynx. All of these patients had received radiation. In two cases which involved the antrum, the exophthalmos seemed to be secondary to an infection. In all the other cases it was thought that it was due to an extension of the new growth into the orbit. This was based on the fact that in some instances a mass was palpable in the orbit, in some there were signs of peripheral involvement of the nerves traversing the orbit, in some a papilledema and in some an indentation of the scleral wall. I have observed no instances in which I felt that the radiation per se was a significant factor in the exophthalmos. If radiation in moderate doses, as given in Dr Schall's cases were a cause of exophthalmos, exophthalmos would frequently be seen in patients in whom fractionated doses of 6000 and 7000 roentgens are given to portals which include the orbit and which produce a blistering dermatitis of the eyelids and adnexa and in some instances a necrosis of a portion of the cornea. It is significant that exophthalmos is not seen as a feature in such instances.

DR JOSEPH C BECK, Chicago. One must always differentiate in these cases between whether the complication is due to the action of the x-rays and radium on the tissues or whether other factors may have contributed such as trauma following operation. Medicaments, such as caustics, may have been applied locally. Nevertheless, if one can show, in these otherwise fatal cases, that the x-rays and radium cured the condition, one can ignore the complication of exophthalmos. My contribution to the discussion of this paper lies in recording my observation in malignant disease about the head and neck treated by x-rays and radium alone or combined with surgical procedures: the cold knife, the endothermic knife, the actual cautery, and caustics such as zinc chloride being used. I have yet to observe one case of any degree of exophthalmos following irradiation with either x-rays or radium. On the other hand, I have seen exophthalmos develop when irradiation was done postoperatively. In these cases I have always been satisfied that the exophthalmos was due to the extensive and severe reaction from surgical intervention with its subsequent venous and lymphatic block. Having been present at many radical operations for malignant disease of the sinuses, especially by the thermic method (G B New, Rochester, Minn. and G E Ohngren, Stockholm, Sweden), as well as having used similar methods myself, I can visualize how the extensive heat could radiate far beyond the point of application and thus block the return circulation. Reference was made in the paper to a small tumor of the sinuses reported by Goldsmith. This was treated with radiation, and exophthalmos followed. It is necessary to know by exact measurements with an exophthalmometer the degree of exophthalmos before and after treatment. One should also know the technic employed. Permit me to suggest that experimental work be done on animals by means of excessive irradiation. It will be granted that the anatomy is comparative and that the pathologic changes will not be comparable to that of the cases here recorded. I am connected with a large public institution where several hundred cases of malignant growths are treated including those of the sinuses. Much irradiation from x-rays and radium is used by all types of application. From the report of the chief of the tumor clinic, as well as from my own observation, exophthalmos has not been present very often as the result of irradiation.

DR. LEROY A SCHALL, Boston. I do not have much more to say except to thank those who discussed the paper. In reply to Dr Reese I would say that there was no tumor involvement of any of the orbits which required exenteration. Exenteration was done in four cases. One patient recovered without the necessity of exenteration. It may be that I chose a minute subject for presentation but as a surgeon I am convinced that the condition causes considerable worry and that little help will be obtained from any one else when this type of case is handled.

RENAL LESIONS DUE TO DIETHYLENE GLYCOL

A PRELIMINARY REPORT

H D KESTEN, MD, M G MULINOS, MD
AND
LEO POMERANTZ, BS
NEW YORK

A report¹ of several fatalities following the use of an "elixir" of sulfanilamide made with diethylene glycol prompts this preliminary abstract of a portion of the work in progress on the pharmacology and pathology of the glycols and related chemicals. Only two studies of the toxicity of diethylene glycol appear in the literature. Von Oettingen and Jirouch² found, using four mice that the minimum lethal dose was approximately 5 cc per kilogram of body weight when given

Fig. 1.—Kidney of rat receiving 5 per cent diethylene glycol in drinking water for seventy-two hours. Vacuolization and swelling of epithelium of convoluted tubules. Distention of glomerular spaces. $\times 110$

subcutaneously. Haag and Ambrose³ reported that the ingestion of the glycol in concentrations of 3 per cent and 10 per cent in drinking water was rapidly fatal to rats and that the minimum fatal dose for rabbits is 2 cc intravenously. The vital organs of these animals were found to be essentially normal.

EXPERIMENTAL WORK

Diethylene glycol was administered to 107 young adult white rats and to twenty-six rabbits in the following manner. All the animals studied were kept on a

The expenses of this research were partially defrayed by the Philip Morris Fund.

standard laboratory diet except that the only source of fluid for the rats was that containing diethylene glycol. The diethylene glycol was of commercial grade, manufactured by the Carbide and Carbon Chemicals Corporation.⁴

Rat group B, seventeen animals, 0.5 per cent in drinking water for from thirty-three to 124 days. No deaths occurred as a result of the procedure.

Rat group C, thirty animals, 1 per cent in drinking water for from thirty-three to 174 days. No deaths occurred from the procedure.

Rat group K, twenty-five animals, 3 per cent in drinking water for from fifteen to ninety-five days. Fourteen died in from five to fifty-six days with extensive degeneration of the renal cortex. The remaining eleven, killed after from fifty-one to ninety-five days, were normal.

Rat group F, thirty-five animals, 5 per cent in drinking water for from one to six days. Nine died in from one to six days as

comatose and often anuric. The blood nonprotein nitrogen rose progressively in both sets of animals from eight to ten times normal.

Fig. 2—Kidney of rat receiving 5 per cent diethylene glycol in drinking water for seventy-two hours. Vacuolization and necrosis of convoluted tubule epithelium. Distention of glomerular space. $\times 315$.

as a result of similar renal insufficiency. The remaining twenty-six were killed after from one to six days. The kidneys of twenty-two were also involved, in some cases as early as twenty-four hours after the onset of the experiment. The average daily intake of glycol water in the several experiments was approximately 30 cc per rat.

Rabbits, twenty-six adults, received 1 or 2 cc per kilogram of body weight of pure diethylene glycol or 2 or 4 cc per kilogram of 50 per cent glycol in a single intravenous injection. Eight died in from one and one-half to eight days following a period of anuria with nitrogen retention. The remaining eighteen rabbits were killed after from one to forty-four days. Half were found to be normal. Half exhibited kidney lesions similar to those in the animals which died spontaneously, in one instance only twenty hours after receiving 2 cc of diethylene glycol per kilogram of body weight. Control animals on the same stock diet remained normal.

PATHOLOGY

Most of the rabbits passed smoky urine giving a positive benzidine reaction for several hours after the injection. Terminally both rats and rabbits were

⁴ Identical lesions have since been obtained in a few animals by the use of redistilled diethylene glycol.

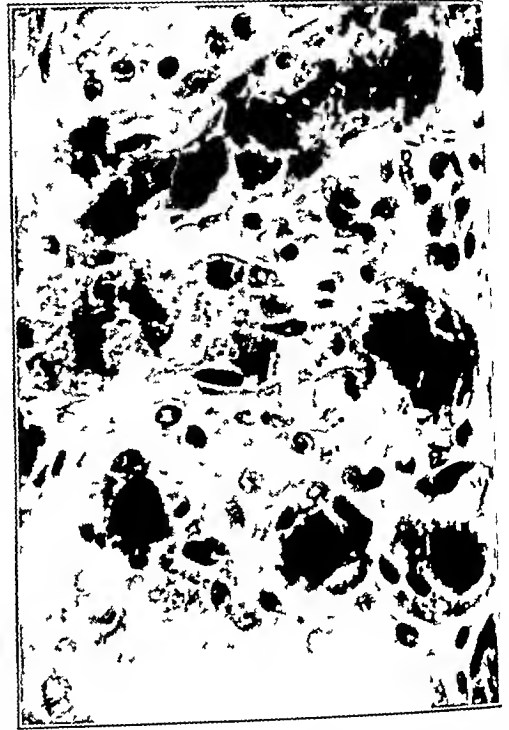

Fig. 3—Kidney of rabbit receiving 1 cc of diethylene glycol intravenously, killed on ninth day. Calcification and regeneration of convoluted tubules. $\times 460$.

Fig. 4—Liver of rabbit dying thirty-six hours after intravenous injection of 4 cc of 50 per cent diethylene glycol. Swelling and vacuolization of liver cells. $\times 75$.

The significant lesions in the affected animals are uniformly in the kidneys, with somewhat less frequent involvement of the liver, and occasionally of the adrenals.

The kidneys are commonly swollen to twice the normal size. The pale yellowish tan cortex is smooth externally and has lost its striations. The medulla often appears congested and moist. Microscopically the process is characterized by widespread, sometimes total, destruction of the epithelial cells of the convoluted tubules. The cells swell and acquire large clear vacuoles which are free of fat and glycogen. This appears to be a form of hydropic degeneration (figs 1 and 2). Occasionally, however, a little finely divided fat is present in the epithelium of both the convoluted tubules and the glomeruli. Necrotic cells are numerous in the severe lesions. Calcification of necrotic cytoplasm may set in as early as the fifth day in rabbits and attempts at regeneration may be present (fig 3). The swollen, vacuolated or necrotic cells completely occlude the lumen of the tubules, resulting in dilatation of the glomerular spaces. The glomeruli are often bloodless and compressed but are otherwise essentially uninvolved. Changes in the medulla are confined to congestion and the occurrence of many hyaline and granular casts in the collecting tubules, with occasional fatty changes.

The liver, though less frequently involved may be enlarged and pale. The cytoplasm of many of the liver cells becomes distended with both large and small vacuoles, which again are free of fat and glycogen (fig 4). Necrosis is not present.

A similar fat-free vacuolization is sometimes found in the epithelial cells of the outer fourth of the adrenal cortex.

Analogous experiments with ethylene and propylene glycols have not produced comparable lesions. Insufficient work has been done to date with dipropylene glycol and with the mono-ethyl ether of ethylene glycol to warrant a definite statement. The observations suggest that the ether linkage of the di-glycols may be the portion of the molecule responsible for the degeneration of epithelial cells of parenchymatous organs, especially of the kidney.

SUMMARY

Diethylene glycol, administered to rats by mouth and to rabbits intravenously, caused extensive injury to the epithelium of the renal convoluted tubules, leading to urinary obstruction and uremia. The liver and adrenals were less regularly involved.

A dose of from 1 to 2 cc per kilogram of body weight intravenously to rabbits was required. The ingestion by rats of 0.5 and 1 per cent solutions in their drinking water in quantities of approximately 30 cc daily per rat for from one to four or five months caused no renal or other symptoms. Three per cent (0.9 cc per rat daily) in the drinking water killed about 50 per cent of the rats within two months. Five per cent diethylene glycol (1.5 cc per rat daily) killed 25 per cent within a week.

Noise Problems in England—The National Physical Laboratory has made measurements and analyses of many noises of very varied origin. Among the noise problems on which the Laboratory has been consulted in recent years are the mitigation of the noises associated with aeroplane cabins and engine testing factories, trains, ships, tube railways, busses, motor horns, pneumatic drills, printing works, transformer substations, cathedrals, assembly halls, business offices, flat miniature rifle ranges, building operations and so on. Assistance is also being given in connection with the Home Office experiments on air-raid warnings.—Kave G W C. *Noise and the Nation Nature* Sept 11 1937 p 446

TORCH OIL DERMATITIS

ITS RELATION TO EPIDERMOMYCOSIS ("RINGWORM")

ADOLPH G KAMMER, M D
Chief of Examining Clinic Inland Steel Company

AND

RICHARD H CALLAHAN, B S

EAST CHICAGO IND

The constantly increasing list of materials which are causative agents in the production of disabling industrial dermatoses has in recent years caused justifiable concern to industrial management. Plant physicians and dermatologic consultants are more and more put to the test of solving the difficult questions of etiology, pathogenesis and effective treatment.

The now widely used patch test, as emphasized by the excellent work of Sulzberger,¹ has proved to be especially useful in determining the specific causes of these dermatoses. As a rule, even the well trained observer gets little help in the discovery of cause from the physical appearance of the lesions. The stages of erythema, vesiculation, varying degrees of induration, fissuring, oozing, scaling and pigmentation at one phase or another are common to most industrial dermatoses. The factors of configuration and distribution are not of much help. The removal of the victim from contact with substances to which he shows a positive reaction by patch test may at once clinch the diagnosis and effect a cure. When cure does not follow such a step one invokes the usual explanations, e g, altered sensitivity to other materials or secondary scratch dermatitis.

The problem here considered is a dermatitis among machinists in a steel mill, for some years past referred to by plant physicians and workers as oil dermatitis. A total of thirty machinists, all of the white race, have been studied to date. Twenty-two complained of an eruption on the hands. These machinists take rolling mill equipment apart, grease it and reassemble it. One step of the operation is to clean machine pieces with torch oil, a crude kerosene.

After working at this job for from six months to a year, the men notice that their hands begin to have a burning sensation and to feel "dried out" after contact with torch oil. These first symptoms are relieved by scrubbing off the oil and greasing the hands with a cold cream or a "palm" oil which is furnished them. After varying periods of time the skin along the lateral margins of the fingers and the dorsa of the fingers and hands begins to have fine, deep seated vesicles which are intensely pruritic. The combination of scratching and further contact with torch oil makes the lesions worse, and the skin soon cracks and oozes. The lesions increase in number and extent until the hands and forearms are involved. The men all reported that the condition becomes aggravated during hot weather and frequently disappears entirely in winter. One man stated that his exacerbations followed attacks of head cold, of which he had many throughout the year. Another man had learned to control his lesions by applying tincture of iodine to new vesicles as soon as they made their appearance.

Read before the Section on Dermatology and Syphilology at the Eighty Eighth Annual Session of the American Medical Association, Atlantic City, N J, June 9 1937.
¹ Sulzberger M B and Wile I red. The Contact or Patch Test in Dermatology. *Arch Dermat & Syph* 23 519 (March) 1931.

Examination of these workers revealed a uniform process. The earliest lesions were fine tense, intra-dermal vesicles, occurring usually in clusters. They were located anywhere on the hands or fingers, but the most common sites were the lateral surfaces of the fingers and the interdigital webs. The older lesions were slightly larger vesicles, in some instances with loose walls. In places with chronic lesions one saw fissuring, oozing, scaling, and "empty vesicles." A

Fig. 1—Torch oil dermatitis (case 9). The medial surface of the left ring finger shows a small cluster of new vesicles in a chronic patch. Fungi were recovered from lesions of the hands in this case.

common site for chronic lesions was an interdigital web. One worker had superimposed pyoderma. During the period of study a man was observed who had many new vesicles on the hands and a generous crop of identical lesions on the skin of the feet and ankles up to the level of his shoe tops. These lesions had appeared immediately after a very hot week-end during which he had been away from work.

Complete examination of these machinists revealed no other condition common than interdigital erosions and vesiculation thus indicating clinical epidermomycosis of the toes in varying degrees of activity. Only one was found to be free from such interdigital conditions, and he was one of those who had never had oil dermatitis. On patch test he was found to be very sensitive to torch oil.

The appearance of the oil dermatitis in these cases, its clinical course, the seasonal variation of its activity and its association with epidermomycosis made it seem worth while to investigate the possibility of a compound etiology, especially with respect to primary or secondary manifestation of epidermomycosis superimposed on a chronically irritated skin.

EPIDERMOMYCOSIS AND MYTIDS

Of the wide variety of lesions now known to be caused by fungi one need consider here only interdigital epidermomycosis and its possible sequelae. Its occurrence is almost world wide.² One finds nearly all adult industrial workers infected, and it is probable that lesions of the toe are the first manifestations of the disease among this class.

The interdigital lesion changes in appearance according to the stage of its activity. During warm weather and periods of increased foot strain one finds moist malodorous plaques occasionally with erythema, vesiculation, oozing and crusting. With the arrival of cooler weather or with decreased foot strain there is subsidence, the lesion frequently presenting no more to the examiner than a shiny surface with a few fine scales between the fourth and fifth toes. Dissemination of the infection from the toes to the moist creases

and accessible dry surfaces of the body is external in way of the patient's own fingers or contact matter. The new lesions, as well as their predecessors harbor fungi, and both are considered foci of primary involvement.

Organisms entering the blood stream from primary foci are probably distributed to the skin of the entire body. Their advent is followed after some time by an altered tissue reactivity (allergy). Subsequent dissemination through the lymphatics or blood stream from a primary focus produces an acute inflammatory response and secondary lesions, mytids (epidermomytids or dermatophytids).³ Mytids may mimic primary infections to an amazing degree. A common site for their appearance is the hands.

The acute inflammatory reaction which characterizes the development of mytids presumably causes the rapid destruction of any fungi present at the site. Fungi are rarely recovered from these secondary lesions, a fact which must occasionally be relied on to distinguish them from primary foci. The whole process resembles the pathogenesis of tuberculosis of the skin.

Several workers have produced strong evidence in support of this theory. Cleveland White⁴ obtained a positive fungus culture from an inguinal node associated with an active eruption on the foot. Peck and others recovered the organism from the blood of patients. Lesions identical with mytids can be produced in allergic subjects by the injection of trichophyton,⁵ and injection of trichophyton may cause exacerbation of existing lesions. People who have or have had epidermomycosis react with a local inflammation to intradermal injections of trichophyton, overdoses produce severe systemic reactions.

The possible interrelationship of fungous infection and other known causes of cutaneous disturbances has engaged the attention of other workers. Beerman, in his study of leather dermatitis, concluded that an infection of a fungous nature can produce a polyvalent

Fig. 2 (case 1)—Typical involvement of the backs of the distal portion of the hand.

allergy of the skin which is responsible for reaction not only to the specific toxin, trichophyton, but to a wide group of substances, among them leather. White and

Taub⁸ had previously reported eighteen cases of a similar type and were the first to report this phenomenon. They expressed the belief that a fungous infection can cause sensitization of the skin to materials which otherwise are innocuous. Wise and Sulzberger⁹ also have contributed to this conception of a polyvalent sensitization by their work on eruptions due to drugs. They said that fungous infections cause the broadening of a sensitization to include other materials and also cause a dermal injury which results in the more effective penetration and action of other materials on the tissues.

The conception of Stokes and Kulchar¹⁰ with regard to this problem seems to be more applicable than the foregoing as an explanation of the pathogenesis in the cases here presented. They described an "infectious allergic complex" involving fungous infections which manifested themselves after the administration of arsphenamine. They cited four patients who had previously exhibited no active epidermomycosis but who, after receiving arsphenamine, had acute epidermomycosis of the hands and feet. Their cases included several flare-ups of epidermomycosis following arsphenamine therapy, in which the arsphenamine was considered a contributing allergic factor.

The thought that dermatosis supposedly caused by a contact irritant might in reality be a fungous disease is not new. Indeed, the appearance of the two conditions is so frequently similar that dermatologists have at times felt called on to warn industrial physicians against the pitfall of passing off a bona fide contact lesion as just another superficial fungous infection. Foerster¹¹ recently made a strong plea for more careful differentiation, and Wise and Wolf¹² expressed the belief that a diagnosis of typical fungous dermatosis should not be made unless the patient presents an undoubted focus. It is probable, however, that the criterion of a primary focus is at present too easily met, and it seems that a greater consideration of other factors should be made an additional requirement.

EVALUATION OF CAUSATIVE FACTORS

1 *Torch Oil*—As previously stated, the men take down rolling mill machinery, clean the parts with torch oil and regrease and reassemble them. It was possible to perform patch tests with the oils and greases on twenty-eight of the thirty men studied. The patch test materials were clean grease, old grease, new torch oil and used torch oil (torch oil plus old grease). The two greases were found to be innocuous in all instances.

All the men tested showed some degree of susceptibility to irritation by torch oil. The positive reaction varies from faint erythema to marked inflammation with vesiculation and resembles the type of irritation of the skin one sees with the local therapeutic use of such things as mustard and turpentine. The degree of sensitivity to torch oil seems to vary with the complexion. Light and red-haired persons are readily irritated and dark-skinned men are not.

Men who show considerable sensitivity to torch oil by patch test do not necessarily acquire chronic dermatitis. In this group of thirty machinists there were twenty-one men whose reactions were read 3 plus or 4 plus. Of these, four had severe cases, five had moderate cases, eight had mild cases and four had no oil dermatitis. The last group presented strong evidence that at least one factor other than susceptibility to irritation enters into the etiology of torch oil dermatitis.

It was found that seven men were only slightly (2 plus or less) sensitive to torch oil. In one instance the irritation was almost insignificant and the reaction was read a questionable positive. This man had no dermatitis. Of the remaining six, three had mild cases and three others had clear hands.

It was concluded from these facts that a worker who shows little or no irritation by patch test will not have more than a small amount of torch oil dermatitis if he acquires it at all. Further, a man who shows considerable sensitivity probably, but not necessarily, will acquire that condition.

2 *Epidermomycosis*—It was found that twenty-four men had undoubted interdigital epidermomycosis ("athlete's foot") in varying stages of activity. In five other instances that diagnosis could be made only with reservation, and in one the skin between the toes appeared normal. In none of the last six cases was it possible to examine the skin scrapings. In the five instances in which the diagnosis of interdigital epidermomycosis was questionable, four of the men had no oil dermatitis and one had only a mild case. Patch tests with torch oil in these cases showed considerable irritation in four and moderate irritation in one. Only one man was considered to be free from superficial fungous lesions, and he had no dermatitis of the hands in spite of the fact that he was a blond who was found by patch tests to be very susceptible to irritation by torch oil. The exposure of these six men to that substance at work was equal to or greater than the average for the entire group.

The twenty-four men who had undoubted fungous lesions on the feet showed great variation in the appearance of their hands. Twelve men were considered to have small but definite involvement between the toes (1 plus). Of these, seven had mild cases of chronic dermatitis on the hands, two had moderate and three had severe attacks. Nine men had a moderate degree of superficial mycotic infection (2 plus). Three of these, whose reactions to patch tests with torch oil were only weakly positive, never had dermatitis. Three others had mild attacks only and three had from moderate to severe cases. Three workers had considerable interdigital epidermomycosis (3 plus and 4 plus), among whom there were one case of mild and two cases of moderate dermatitis on the hands.

It appears, then, that a man who has torch oil dermatitis must, in the first place, be susceptible to irritation by that substance. This factor is of both qualitative and quantitative importance. In the second place, such a man must have a definite primary focus of superficial fungous infection. The extent and activity of that primary focus do not predict the seriousness of the oil dermatitis nearly as accurately as does the factor of sensitivity to torch oil. From the data here presented one may assume that the disease does not occur in the absence of either factor (tables 1 and 2).

The amount of exposure to torch oil was too uniform throughout the series to warrant its separate evaluation.

The usual laboratory procedures gave negative results in all of the cases except one, in which the Kahn reaction of the blood was positive

DIAGNOSIS OF SUPERFICIAL FUNGUS DERMATOSIS

It seems that the procedures in investigating the possible implication of fungous disease in cases of torch oil dermatitis should be as follows

- 1 Establishment of the diagnosis of interdigital epidermomycosis by laboratory methods (direct smear and culture)
- 2 Examination of material from the lesions on the hands for the presence of fungi
- 3 Biologic tests, such as inoculation with trichophyton
- 4 Blood cultures, in an attempt to recover circulating fungi
- 5 Consideration of case histories
- 6 Proper evaluation of therapeutic tests

Discovery of a Primary Focus—There was undoubted physical evidence of interdigital lesions in twenty-four of thirty men studied. It was possible to study material from the toes of sixteen, all of which showed the presence of fungi. It was found that active lesions yield organisms abundantly and that with the exercise of painstaking search fungi are demonstrable in quiescent patches. For good results it is necessary to obtain material from beneath the superficial scales and to clear the preparations with potassium hydroxide for long periods. Both of these steps have been described in detail by Cleveland White.¹³

When speed of diagnosis is not essential, the use of cultures is worth considering. Material obtained from beneath the scales is soaked for about five minutes in 90 per cent alcohol and planted on Sabouraud's medium. There is a characteristic growth of fungi in from ten days to two weeks, which is recognized at a glance by

the trained worker and which can be further identified by microscopic examination. The whole procedure is carried out with a much smaller total expenditure of time than one spends in the direct search of fungi in skin material, especially in lesions of low grade activity. The practical value of cultures is materially diminished by the fact that growth does not occur in all cases showing fungi by direct examination. We were able to culture organisms in only three of sixteen cases in which there were demonstrable fungi in material taken from lesions of the toes.

Examination of Material from Lesions of the Hands—Fungi were searched for in the lesions of the hands in fifteen cases. Vesicles were clipped off at their base and prepared with potassium hydroxide in the same manner in which material from the toes was treated. Some of the vesicles in each instance were immersed in 90 per cent alcohol and subsequently planted on Sabouraud's medium. In two instances, fungi were found by direct examination, and in one of these the organism could be cultured. The lesions in these two cases were, by definition, primary foci of fungous disease. Because in appearance they were indistinguishable from similar lesions on the hand of other patients, it was considered that the latter might be mytids.

Blood Cultures—Blood cultures were made for six of the sixteen patients who had demonstrable fungi in the lesions on their toes. The routine followed was to add 2 cc of the patient's blood to 5 cc of sterile broth. A second portion of 1 cc was layered on a slant of Sabouraud's medium. No fungi grew by either method. The procedure was carried out with forty other workmen, not machinists, selected because they had acutely active epidermomycosis of the toes and one or more other places (e.g., groin, axilla, gluteal fold). No fungi grew in any case, indicating what is already well known, namely that it is extremely difficult to obtain positive blood cultures in infections of this type.

The Use of Trichophyton¹⁴—Little use was made of this substance. Unquestionably it should have diagnostic value if, when used in small injections or patch tests, new lesions develop or existing ones become worse. That is not, however, to be expected in any appreciable number of instances of proved fungous infections. The usual positive reaction is a papule or a wheal which indicates simply that the patient has had epidermomycosis. Tolmach and Traub¹⁵ reported eight cases in which fungi were demonstrable in lesions on the feet and responses to trichophyton were negative. Seven of their patients presented accompanying vesicular or squamous lesions on the hands.

The facility with which existing primary superficial fungous disease was demonstrated obviated the diagnostic use of trichophyton in the present study. Besides it was necessary to consider the possibility of severe constitutional reactions, which are said occasionally to occur and which in this study might have had serious medicolegal aspects. Intradermal injections were made on four of the men who never had torch oil dermatitis and all showed definitely positive reactions.¹⁶ One of these men had no detectable fungous lesion anywhere.

16 Dr Harry P Jacobson of Los Angeles provided a mixed polyvalent fungus vaccine (so called metaphyton)

and in the other three cases the diagnosis of interdigital epidermomycosis was questionable. No studies of toe scrapings were made in any of these four cases.

Consideration of Case Histories—Machinists with torch oil dermatitis uniformly have exacerbations in summer and improve rapidly with the onset of cool weather. Plant physicians do not see any cases during the winter. During and immediately after peaks of very high summer temperatures there are flare-ups in patients who were doing fairly well under one form of therapy or another.

As was previously noted, one patient had a marked exacerbation of new vesicles in groups following a hot week-end during which he was away from work. At the same time numerous vesicles developed on the feet which were suggestive of a phytid reaction on another part of the body identical in appearance with the torch oil dermatitis on the hands.

A second man had an exacerbation after a day's work during which he had worn rubber gloves to protect his skin from torch oil. In this instance the fungous infection was primary on the hands, the organism having been recovered from one of the vesicles.

The effect of withdrawal from exposure to torch oil could be observed when it became necessary for two machinists to leave work for other reasons. In the first instance the man sustained a Colles fracture which caused his absence from the plant for five weeks. During that time he applied phenolated petrolatum to his hands as was necessary to relieve itching. At the end of five weeks during which the weather was continuously hot his dermatitis had improved only an estimated 30 per cent. In the second instance a worker was advised to leave work because of moderately advanced tuberculosis. He was seen at intervals throughout the spring and summer for a period of four months. He improved to an estimated extent of 80 per cent in that time, but at the last interview it was found that a cluster of new vesicles had recently developed along a finger margin. No attempt had been made to treat the oil dermatitis in this case.

Therapeutic Tests—Previous attempts at the treatment of this condition were uniformly failures. A grand array of standard and proprietary ointments had been used with discouraging results. At the time of this study all the afflicted men were instructed to apply Whitfield's ointment to the hands and to daub the toes with a solution of 10 per cent salicylic acid, 5 per cent benzoic acid and 1 per cent phenol in alcohol. There was rapid and definite improvement in the entire group for a short time, after which the majority ceased reporting for observation and treatment.

A group of eight men continued to be cooperative and were seen daily. Four of these were kept on treatment. Their toes were painted on three successive days with the alcohol solution and for eleven days afterward with tincture of merthiolate (Lilly), and at the end of the two weeks the painting with the alcohol solution was reinstituted. The men took soap and hot water foot baths daily, rubbing off all removable scales with towels. Their hands were kept covered with applications of 10 per cent sulfur and 5 per cent salicylic acid in petrolatum. New crops of vesicles were painted daily with the alcohol solution until they began to dry, usually after three or four days.

The remaining four men were used as controls. They were supplied with good surgical hand brushes and tincture of green soap with which to scrub off all torch

oil at the end of a shift. After this cleansing they greased their hands thoroughly with phenolated petrolatum. No treatment was given the feet.

For about two weeks the control group improved more rapidly than did the four treated patients. Soon after the onset of a severe July heat wave however, the entire control group had exacerbations and asked to be placed on the "ringworm treatment." The two men considered most likely to cooperate were added to the treatment list, and we carried on through the rest of the summer with six men all of whom continued to do their regular work.

The progress of these six men was considered satisfactory. Complete cures were not obtained in any of their cases, but the men were able to work comfortably all summer and fared much better than any of their fellow workers. At no time during the summer was the dermatitis in any treated patient as severe as it had been in the late spring, when this study was started. The cases in which there was the most extensive epidermomycosis of the toes were those in which therapeutic

TABLE 2—Summary of Studies on Men Without Dermatitis

Case	Torch Oil Patch Test	Mycosis of Toes	Fungi in Toe Lesions	Comment
1	4+	0	Not examined	Positive reaction to trichophyton
2	1+	2+	Not examined	
3	4+	?	Not examined	Positive reaction to trichophyton

6	?	2+	Not examined	
7	4+	?	Not examined	Positive reaction to trichophyton
8	2+	2+	Not examined	Positive Kahn reaction of blood

progress was slowest. In none of the six cases could one be satisfied that the lesions on the toes had entirely cleared.

BACTERIOLOGIC STUDIES WITH TORCH OIL

Previously to this work it was assumed by the plant personnel that oil dermatitis was a contagious disease. The causative organism was believed to be transmitted through the oil from worker to worker, gaining entrance by way of the small abrasions in the skin which machinists constantly sustain.

A careful inquiry into case histories yielded information which strongly contradicted that theory. One of the first workers to be examined had pyoderma superimposed on his oil dermatitis. Though he had worked in the same torch oil as his fellow workmen for weeks, none of the other men had pus-forming lesions. More conclusive than this evidence was the discovery by some of the machinists that torch oil made a good antiseptic application to scratches and abrasions. Wounds anywhere on the body so treated never became infected and healed rapidly. The use of torch oil in this way is of course confined to men who are not readily irritated by that substance.

Experimental work done with the torch oil showed that it was always sterile regardless of how long it had been in use. Small amounts (2 cc) placed in plain broth in blood broth or on agar slants never showed growth of any organism.

A culture made in the case of oil dermatitis complicated by pyoderma showed pure *Staphylococcus*

albus A loop of this culture spread on a plain nutrient agar slant and immediately covered with a film of torch oil failed to grow. With the substitution of 2 per cent blood agar for plain agar there was a scant growth in twenty-four hours. When a plate of growing colonies on plain agar was covered with torch oil no further growth occurred, but on transplanting those colonies after twenty-four hours under torch oil there was apparently normal growth.

All the colonies of *Staphylococcus albus* which could be recovered from an agar slant of virulent organisms were transferred to a small vaccine bottle containing about 20 cc of torch oil and a few sterile glass beads. The vial was shaken vigorously for one minute, after which 1 cc portions were withdrawn through the rubber stopper by means of a hypodermic syringe and needle and layered on agar slants. There was growth of *Staphylococcus albus* after five and after ten minutes, but after fifteen minutes the suspension of bacteria in oil was sterile. The experiment was controlled by the substitution of sterile distilled water for torch oil in the vaccine bottle. After one and one-half hours of continuous shaking in a motor-driven shaker there still was growth of *Staphylococcus albus*.

TORCH OIL BURNING

Very susceptible persons naturally may be irritated more readily by contact with torch oil than were any of the machinists reported on in this study. Such an instance came to our attention when a machinist's helper had an acute vesicular eruption on the hands and fingers after working for only one day with torch oil. The skin of his hands was generally erythematous, the vesicles were uniformly distributed and not in clusters, and they were superficial and variable in size. The man was removed from contact with torch oil, and in nine days his skin was entirely clear. This acute burning is essentially different from chronic torch oil dermatitis. The latter condition develops only after months of exposure, and the original vesicles are small, uniform in size and deep seated. Further, the vesicles are grouped in clusters, batches appear from time to time and cure does not follow shortly after removal from contact.

COMMENT

Torch oil dermatitis is probably incipient during the first months of a worker's contact with torch oil. At this stage the condition manifests itself subjectively only, with a sense of dryness, tingling and some itching. A few men report that the skin "looks dried out" at that time. The symptoms at this stage are relieved by washing off the torch oil and greasing the skin with any nonirritating oil or grease.

It is probable that the damage to the skin caused by torch oil rests mainly on its solvent qualities and that its chief deleterious action consists of removing the normal skin oils. There is in addition a mild irritation caused by torch oil that is produced by all oils of its approximate volatility and hydrogen unsaturation.¹⁷ This irritation is seen in patch tests on persons of varying susceptibility, and one encounters a rare person in whom acute vesicular eruptions occur from ordinary contact at work. The physical irritation which torch oil causes to the skin varies noticeably with one factor only, the person's complexion.

In the usual case the incipient stage lasts from three months to a year, and then crops of small vesicles make

their appearance. It is probable that in most cases the vesicles are epidermomytids. They appear with the coming of the first hot weather, and they usher in the sequence of eczematoid dermatitis: vesicular, fissuring, oozing, crusting, scaling and discoloration. Workers with no primary foci of fungous infection do not acquire lesions on the hands. The dermatitis becomes aggravated by further exposure to torch oil which now causes erythema and intense smarting. New crops of vesicles develop from time to time, usually during or just after hot weather. Their appearance is often independent of recent exposure to torch oil.

The conception that a focus of fungous disease might make a worker more susceptible to a contact irritation does not hold here. In the case of one machinist there was no fungous lesion, yet the man was shown by patch test to be very susceptible to irritation with torch oil. Another worker had definite interdigital epidermomycosis, and the reaction to his patch test with torch oil was at most only questionably positive. In neither of these men was there ever any evidence of oil dermatitis. It is probably true that the chronic irritation associated with contact with torch oil alters the skin of the hands in such a manner as to favor the subsequent development of epidermomycosis and mytids. When no focus of primary fungous disease exists there can be no mytids, and when torch oil does not cause appreciable cutaneous irritation mytids fail to appear on the hands in spite of active fungous lesions elsewhere.

SUMMARY AND CONCLUSIONS

1 In the industrial dermatitis of the hands described there probably is an interrelationship between contact with torch oil and the existence of a focus of superficial fungous disease. This conclusion is arrived at through the following observations: (a) No case of dermatitis was seen in workers who did not also have interdigital epidermomycosis of the feet, (b) fungi were recovered from lesions of the hands in two out of twenty-two cases, (c) the clinical course of the affliction closely simulates that of fungous disease, and (d) therapeutic measures ordinarily employed in the treatment of epidermomycosis are of unusual value in torch oil dermatitis.

2 The demonstration of a focus of fungous disease is not enough to warrant the incrimination of that infection in the development of an industrial dermatitis. Such foci probably exist almost universally among laborers at the present time.

ABSTRACT OF DISCUSSION

DR. HARRY R. FOERSTER, Milwaukee. The authors have called attention to a series of cases that represented what in their industry had been considered an occupational dermatosis, so-called torch oil dermatitis, and they have shown that with one or two exceptions these are not cases of torch oil dermatitis but cases of epidermophytid reaction occurring in persons previously sensitized by contacts with torch oil. It is significant that the patients who were examined who had epidermophytosis on the feet and negative patch tests with torch oil failed to develop dermatitis or phytid reactions on the hands. There is apparently an interrelationship between fungous infection on the feet, the contact and sensitization to torch oil, and the development of phytid lesions. Most dermatologists are familiar with the process by which a fungous infection on the feet or groins, and subsequent phytid reactions on the hands, predispose to the development of contact dermatitis. In the cases presented by Drs. Kammer and Callahan the reverse exists, chemical contact sensitization appearing to favor the development of an epidermophytid reaction. The question may properly be put whether a condition like this

actually occurs or whether these patients may not have previously had mild phytid reactions on the hands that were not recognized by them and did not provoke active dermatitis necessitating medical care but which in turn favored the development of a contact dermatitis subsequently, on continued exposure to torch oil, leading to the development of clinical dermatitis only on the sites of preexisting phytid lesions. This would not produce a picture of diffuse contact dermatitis but of discrete vesicular and squamous lesions at sites of allergic epidermis. The authors have also demonstrated in their investigation the value of patch tests in the study of contact dermatitis and that they are not infallible. They have obtained positive tests when one would expect negative, and they have failed to obtain positive tests when they should logically have appeared. The authors have also demonstrated in their investigation the value of patch tests in the study of contact dermatitis and that they are not infallible. They have obtained positive tests when one would expect negative, and they have failed to obtain positive tests when they should logically have appeared. The authors have also demonstrated the practical value of examination for the fungus in fresh specimens of skin and also, from the point of view of routine office and factory work, the impracticability of Trichophyton tests, blood cultures and cultural growths of skin specimens. The question that arises, if these are accepted as having been phytid reactions in patients sensitized by previous exposure to torch oil, is whether such cases are compensable. I believe that a condition of this type, even though it is not a contact dermatitis, should be accepted as an occupational disease and therefore a compensable disease when it produces disability because its development apparently requires a combination of circumstances one of which is occupational.

DR CLEVELAND J WHITE, Chicago. The belief of the speakers that the prolonged low grade chemical torch oil contact predisposes the skin of the hands to secondary fungous infection is well received and will be confirmed by other investigators. At Dr Kammer's invitation I had the opportunity of studying every case history that was outlined here, and I see no flaws in the interpretations given by the authors. The possibility of finding fungi in lesions of the hand is extremely difficult, as we have all found out. If there is anything I might add it is that these cases in which the fungi were not found may well be actual fungous infections rather than phytid on account of the response to therapy. Furthermore, I should say that some conclusions can be accepted from some of our work at Northwestern University Medical School a few years ago in which we took fungi from between the feet and planted them on the back of a rabbit's skin. The fungi quickly changed their morphology, the lesion persisted and in time the fungi disappeared altogether. This phenomenon could account for some of these lesions here. The nouse of the biologic extracts is to be commended because of the legal angles. They are a double edged sword and may produce a great deal of trouble, and I feel that the diagnosis was well established without using them. Furthermore, I believe all experience has shown that the use of biologic extracts has not made an exact diagnosis of superficial fungous infection. Like Dr Foerster, I extend my congratulation to men who are busy in a routine clinic and are not stimulated by the walls of a great research and teaching institution, in the solution of the phase of these eczematous eruptions of the hands.

DR ADOLPH G KAMMER, East Chicago, Ind. In answer to Dr Foerster's question as to the possibility of the existence of small phytids in these men before they were exposed to torch oil, I cannot give a definite answer. The only thing I can give is the histories of the men, namely, that they had good hands before they began to work. Shortly after the appearance of small vesicles on the hands the torch oil has a different effect on the men, it then begins to burn intensely and to cause considerable discomfort, and inflammation is evident. There was one man who had lesions, who had been a truck driver in a CCC camp, and he stated that this was simply an exacerbation or a recurrence of the disease which he had as a truck driver. That man had fungi on his hands, he had purely an epidermomycosis.

GLYCERIN, ETHYLENE GLYCOL, PROPYLENE GLYCOL AND DIETHYLENE GLYCOL

REPORT ON FEEDING EXPERIMENTS WITH RATS

HARALD G O HOLCK, PH D
CHICAGO

The substitution of diethylene glycol for glycerin as a hygroscopic agent in industry makes it desirable to compare the toxicity of these two chemicals. Both have high boiling points, 245 and 290 C, respectively. Hence, small amounts may possibly pass unchanged with smoke from a cigaret into the body in addition to anything absorbed from the moist end of the cigaret in the mouth.

In view of the rather high toxicity of the related ethylene glycol and because of the use of propylene glycol as a solvent for iodobismutol, it was thought desirable also to include a rough comparison between commercial samples of diethylene glycol and these two related chemicals.¹

Recent exhaustive studies² have shown that glycerin may constitute a large proportion of the food of rats over long periods and that smaller amounts may be added to adequate diets of growing dogs and of man without apparent harm. In fact, the rats showed normal growth and reproduction on such a diet and glycerin could be substituted for part of the food. Only with very large quantities was there diuretic action in dogs and rats. In spite of this favorable report my associates and I decided to include glycerin in our feeding experiments so as to make certain that the rats had the usual tolerance to this compound.

The recent literature dealing with the properties of the glycols is fairly extensive. A comprehensive paper by von Oettingen and Jirouch³ deals with seven glycols, including ethylene glycol and diethylene glycol. Both caused hyaline shrinking of muscle fiber, ethylene glycol caused a slight and diethylene glycol a questionable hemolysis, methemoglobin formation was absent with ethylene glycol and uncertain with diethylene glycol. The minimal fatal dose in mice was twice as high for diethylene glycol as for ethylene glycol. Both had a slight action on the central nervous system, caused slight hyperemia and muscle rigor and had a slight antiseptic action toward yeast. Diethylene glycol was more depressing to striated muscle than ethylene glycol but had an uncertain depressive action on the intestine as compared to ethylene glycol. Neither caused edema, sensory nerve ending depression or motor nerve fiber depression. The authors concluded:

Local irritation is comparatively small. Their application to the skin seems to be without risk. Given orally in larger doses they may produce severe gastro enteritis and systemic symptoms. For intramuscular injection only small doses should be used, else systemic effects may arise. Subcutaneous injections should be avoided on account of local irritation. The intravenous administration would appear to be dangerous, because of the hemolytic action and of the fall of blood-pressure observed with these compounds.

Ethylene glycol was also studied extensively by Hanzlik, Seidenfeld and Johnson,⁴ who used both intra-

From the Department of Physiology of the University of Chicago. Profs. A. J. Carlson and A. B. Luckhardt gave helpful suggestions regarding this problem.

¹ These two glycols were supplied by the Carbide and Carbon Chemical Corporation, South Charleston, W. Va.

muscular injections and drinking experiments. In chronic feeding experiments on rats, smaller daily doses (0.7 Gm per kilogram) stunted growth but did not injure the kidney, whereas the higher daily dose of 2.2 Gm per kilogram caused variable degrees of ovaluria and renal calculi, verifying previous reports. As a solvent for medicinal products with intramuscular injections it was considered "comparatively innocuous." Hunt⁵ reported kidney injury by oxalic acid formation when ethylene glycol was administered in the drinking water of different species of animals and cautioned against continued administration of small doses to man. In this and a subsequent paper he⁶ also warned strongly against the promiscuous use of ethylene glycol in food products or as a substitute for glycerin. As to propylene glycol he found that, with a 5 per cent solution as the only liquid for drinking, rats showed normal growth and also good tolerance to it when their livers or kidneys had been injured by various poisons. Hunt suggested that propylene glycol may have a "true food value in the sense that ethyl alcohol does, and without the drug action of the latter." Wiley, Hueper and von Oettingen⁷ concluded that low concentrations of ethylene glycol vapor in the air (300 mg per thousand liters) is not toxic when intermittently given to mice or rats as judged by weight curves and histopathologic examinations, although one of ten rats and three of twenty mice died during the tests with 398 mg per thousand liters for eight hours a day, five days a week, sixteen weeks, with no controls to show that similar mortality would occur in untreated rats and mice.

In their extensive study on bismuth excretion in rabbits and patients, Hanzlik, Mehrtens and Spaulding⁸ used ethylene glycol as the solvent for iodobismutol without any untoward effects by this glycol. Seidenfeld and Hanzlik⁹ found propylene glycol to be much less toxic than ethylene glycol in injection and feeding experiments as judged by animal growth and tissue appearance by microscopic examination. No demonstrable accumulation effects were seen with concentrations of from 1 to 10 per cent in the drinking water. However, propylene glycol did cause somewhat greater local irritation than ethylene glycol. Finally, Hanzlik, Mehrtens and Spaulding,¹⁰ in a comparison of propylene glycol and diethylene glycol, concluded that iodobismutol prepared with propylene glycol is less toxic and prepared with diethylene glycol is more toxic systemically than ordinary iodobismutol prepared with ethylene glycol.

Haag and Ambrose¹¹ report that concentrations of 3 and 10 per cent, respectively, of diethylene glycol in the drinking water of rats proved rapidly fatal.

TOXICITY OF DIETHYLENE GLYCOL¹² IN FOOD AND WATER AND THAT OF GLYCERIN IN FOOD, AND ETHYLENE GLYCOL AND PROPYLENE GLYCOL IN WATER

The results of an eleven weeks experiment show that female rats 4½ months old on a control diet of fox-chow (Purina Mills) and water gained in weight about

to the same extent as did those who had eaten fox-chow containing 20 per cent glycerin or 20 per cent water.

However the fox-chow containing 20 per cent diethylene glycol killed five of six rats within four weeks. One kidney (found to be normal) was removed from the sixth sick rat after two weeks, on a normal diet this rat promptly recovered. When the fox chow contained 10 per cent diethylene glycol, three of five rats died within eight weeks, but one showed normal gain in weight. From the fifth rat, which was losing weight, one kidney (found to be normal) was removed after the eighth week. On our control diet this rat recovered promptly. With fox-chow containing 5 per cent diethylene glycol, one out of six rats died after seven weeks and another after ten weeks. Of the remainder, one showed but a slight increase in body weight and the other three had made approximately normal gains.

When the drinking water contained 5 per cent diethylene glycol, the toxicity was markedly greater. All five rats died within eleven days (average duration of life, eight days). However, an equimolecular solution of commercial ethylene glycol (292 per cent) was even more toxic, killing all six rats within six days (average duration of life, four days). On the other hand, an equimolecular solution of commercial propylene glycol (358 per cent) was much less harmful than that containing the diethylene glycol. One of the six rats died after the tenth week and one had lost considerable weight at the end of the eleven weeks. The remaining rats were beginning to lose weight at the end of the experiment. Thus, the commercial propylene glycol appears to be more toxic than the highly purified substance administered to rats by Hanzlik and his associates⁹ or the propylene glycol used by Hunt.¹³

Further analysis of the food and water intake showed that with fox-chow containing 20 per cent glycerin the rats ate 23 per cent less fox-chow per day than the ones fed pure fox-chow, but they ate only 11 per cent less than those who had had fox chow with 20 per cent water as their food. The average daily consumption of glycerin was 2.7 Gm. As to water intake, no conclusion seems warranted because the rats who ate fox-chow containing 20 per cent water drank considerably more water than did the controls, indicating that there may be considerable variation in drinking habits even with animals of nearly the same size.

Considering fox-chow consumption per average hundred grams of gain in body weight during the eleven weeks, 11 per cent less of actual fox-chow was needed when the fox-chow contained 20 per cent of glycerin, indicating that glycerin was used as a food substitute.

The average daily fox-chow consumption was 6 per cent less than in the controls when the fox-chow contained 5 per cent of diethylene glycol. When it contained 10 per cent, the fox-chow consumption was 10 per cent less, or about the same as when the fox chow had 20 per cent of glycerin. Considering again the small number of animals, these differences are not significant. However, the large increase in the average daily water intake (75 per cent) when the fox chow contained 10 per cent of diethylene glycol may indicate an attempt to wash down the ill tasting food with water.

When the diethylene glycol proportion in the fox chow reached 20 per cent, the average daily fox chow consumption declined sharply to 24 per cent of the control value in these quickly dying rats. The even

13 Hunt (footnotes 5 and 6)

sharper reduction in the average daily water intake to 18 per cent of normal indicates that these rats became too sick even to drink.

When the water contained 5 per cent of diethylene glycol, the reduction in average daily eating of fox-chow was even more severe than when the fox-chow had contained 20 per cent of diethylene glycol, the intake went down to 17 per cent of normal. The average daily water intake was also markedly diminished to 31 per cent of normal.

When the water contained an amount of ethylene glycol equimolecular with the 5 per cent diethylene glycol, the average daily consumption of fox-chow was nearly twice and the average daily water intake nearly three times that of the rats that had been drinking 5 per cent diethylene glycol, thus the water intake was nearly normal. Therefore, on an average, the rats took in 27 times more ethylene glycol molecules daily than those of diethylene glycol, which may partly explain why they were dying twice as rapidly.

When an amount of propylene glycol equimolecular with the 5 per cent diethylene glycol was present in the water, the rats ate and drank approximately as much as the control rats, thus, on an average they took in three times as many propylene glycol molecules daily as when diethylene glycol had been added to the water. The latter fact further emphasizes the much greater toxicity of diethylene glycol as compared with propylene glycol.

A COMPARISON OF THE EFFECTS OF GIVING VARYING CONCENTRATIONS OF PURE DIETHYLENE GLYCOL (EASTMAN) IN THE DRINKING WATER OF YOUNG RATS

Because the toxic effects following administration of commercial diethylene glycol may possibly have been due to impurities, we added a nine weeks experiment in which pure diethylene glycol was added in varying amounts to the drinking water of rats which were from 7 to 8 weeks old, concentrations started at a level 20 per cent lower than the one that had killed all rats within eleven days. This new concentration of pure diethylene glycol was thus 4 per cent, it killed three of the five rats within nine days, but the other two survived.

On the lower concentrations of 2, 1, 0.5, 0.25 and 0.125 per cent, respectively, of diethylene glycol, no animals died. However, the average actual and percentage gains in body weight during the nine weeks was less than half of that of the controls. Not until the concentration had become as low as 0.125 per cent were these growth averages exactly up to the control values.

Looking next on the average daily amounts of fox-chow eaten, the values are 24 per cent lower than the control intake when the water contained 2 per cent of diethylene glycol. In case of the two highest concentrations (2 and 1 per cent, respectively), there was also a noticeable diminution in actual water intake to 59 and 67 per cent of normal, respectively.

With the higher concentrations of pure diethylene glycol in the water there were dark discolorations around the genitalia, these were not blood, this indicates that diethylene glycol or some darker decomposition product was being passed in the urine. Thus some diethylene glycol was being absorbed.

In the case of the rats which died acutely from diethylene glycol poisoning, the stomach and intestine showed signs of marked local irritation and in some cases considerable blood and local injury.

Comparing the liver, kidney, lung and myocardium of the rats that had been given commercial ethylene glycol, propylene glycol, diethylene glycol or glycerin in the food or water with those of the control rats, no certain damage was demonstrable to these vital organs as judged by examinations of sections stained with scarlet red or with hematoxylin and eosin. These examinations were done by courtesy of Dr. Paul R. Cannon.

Considering the same four organs of the rats which had been given varying concentrations of the pure diethylene glycol in the drinking water, no certain damage could be seen in the liver, kidney or lung. Dr. Eleanor Humphreys, who carried out these examinations, reported an indication of a possible slight change in the myocardium with the three highest concentrations as judged by the hematoxylin and eosin staining technique, but it was slight and not present in all cases.

COMMENT

The results of these experiments place diethylene glycol between ethylene glycol and propylene glycol in toxicity. A high concentration of glycerin in the solid food (20 per cent) seemed harmless. Diethylene glycol in one fourth of this concentration in the fox-chow and in much smaller concentrations in the drinking water was distinctly harmful as judged by cases of mortality, stunted growth in the young, and impaired reproductive capacity.

Even after prolonged administration of diethylene glycol in the concentration employed, however visible microscopic changes in the liver, kidney, lung, heart and testis were absent. Both the frozen section method and the staining with hematoxylin and eosin were used in the first four of these tissues. Although diarrhea was not observed, I believe that the absence of pathologic changes in these vital organs may indicate that local irritation probably is an important factor in the toxicity.

Because the rat in some cases is much more tolerant to poisons than man, for example, to atropine, and in other cases shows peculiar susceptibilities, for example, delayed death after slightly hypnotic doses of nialal, we do not know with certainty what the relation is with diethylene glycol. However, the report by Hunt⁶ of greater susceptibility of man to ethylene glycol than the rat—comparing the per kilogram dosage—probably means that man is also more susceptible to diethylene glycol.

SUMMARY

1 In an eleven weeks experiment, younger adult female rats gained about the same in body weight as control animals when a high concentration of glycerin (20 per cent) was mixed with their solid food.

2 Similar concentrations of commercial diethylene glycol killed all rats within about two weeks, and even 10 and 5 per cent proved fatal to some of the rats. Diethylene glycol is even more toxic when added to the drinking water. When the rats drank from a 5 per cent solution, the average duration of life was only eight days.

3 With the equimolecular concentration of commercial ethylene glycol (292 per cent) in the drinking water, the rats lived only an average of four days but actually had consumed 27 times as many molecules of ethylene glycol per rat daily.

4 With an equimolecular concentration of commercial propylene glycol in the water (358 per cent), one rat died at the tenth week, one was sick and others were beginning to lose weight at the end. The average daily

intake was three times as many molecules of propylene glycol as of diethylene glycol. This places diethylene glycol between ethylene glycol and propylene glycol in toxicity, but nearer the first one.

5 When pure diethylene glycol was added to the drinking water of 2 months old female rats, some died with the highest concentration of 4 per cent and growth was markedly stunted at this level. Even in the concentration of 0.25 per cent, some indication of impaired growth was detectable.

6 That diethylene glycol was being absorbed with the higher concentrations was indicated by discolorations around the genitalia. With high concentrations, local injury and bleeding of the stomach and intestine were frequently seen in the fatally poisoned rats.

7 In microscopic examinations of the liver, kidney, lung and myocardium the only possible change seemed to be a slight one in the myocardium with 1, 2 and 4 per cent of pure diethylene glycol, respectively, in the drinking water, but even this change was not uniformly present and hence may not be significant. Both the frozen section method and the hematoxylin and eosin staining method were employed.

8 Pregnancy did not occur when males and females were mixed and both received 0.5 per cent of pure diethylene glycol in the drinking water. There was some indication of smaller and fewer litters in females receiving 0.25 and 0.5 per cent in the drinking water when mated with frequently changed fresh stock males.

COMMUNICABLE DISEASE CONTROL IN PRIVATE PRACTICE

CHESTER A. STEWART, M.D.
AND
ERLING S. PLATOU, M.D.
MINNEAPOLIS

Physicians who elect to immunize children against smallpox, diphtheria, scarlet fever, pertussis and typhoid fever are confronted by the practical problem of deciding when to administer each prophylactic procedure. A partial solution of this problem probably can be accomplished through the tendency displayed by young infants to be rather refractory to diphtheria and scarlet fever throughout a considerable period during which they are quite susceptible to smallpox and pertussis. This tendency apparently justifies observance of the general policy of temporarily deferring immunizations against diphtheria, scarlet fever and typhoid fever in order that smallpox vaccinations and pertussis inoculations may be completed in the first six months of life.

Whether smallpox vaccinations should usually precede or follow pertussis inoculations is a debatable question. The customary failure of successful smallpox vaccinations when performed during the first three months of life to cause appreciable systemic reactions is a practical point in favor of the early administration of this preventive measure. Also the greater prevalence of whooping cough and its seriousness during infancy can be advanced as important reasons for giving precedence to pertussis inoculations.

Obviously, many factors deserve consideration when the details of individual programs of immunization are

outlined. We venture, therefore, merely to suggest that smallpox vaccinations and pertussis inoculations be performed under the age of 6 months and that immunizations against diphtheria, scarlet fever and typhoid fever be administered in the following twelve or more months (table 1).

During the past three years we have inoculated 311 children with Sauer's pertussis vaccine (table 2), in most instances between the ages of 3 and 12 months and in the recommended total dose of 8 cc. An average of one and three-tenths years has elapsed since the series was inoculated, and in this interval two members of the group had pertussis, eleven and fourteen months after immunization, respectively. In one instance the disease was of moderate severity, and in the other it was rather mild.

Reactions such as fever and edema, erythema and soreness of the arm have been reported occasionally when full doses of the vaccine were injected. Reports of this character practically disappeared when the plan of giving the vaccine to young infants in six semi-weekly or weekly half doses was tried.

During the past six years we have administered 135,000 or more skin test units of Dick's scarlet fever toxin to each of a series of 526 children (table 2). Owing to some uncertainty on our part relative to the value and significance of the Dick test, this test was not applied as a matter of routine after immunization.

When the toxin was given in five separate doses disturbing reactions, which included vomiting, urticarial and scarlatiniform rashes, joint pains, fever and soreness of the arm were reported with considerable frequency. Although various methods were used to avoid these disturbances, their incidence did not decline appreciably until the plan of giving the toxin in ten semi-weekly or weekly half doses was tried. According to our experience, parents generally feel that the avoidance and the attenuation of the reactions which may attend scarlet fever immunization more than compensate for the inconvenience of five extra visits to the office.

Since we administered Dick's scarlet fever toxin to this series of 526 children, an average postinoculation period of two and seven-tenths years has elapsed, and in this interval four members of the group had a mild form of scarlet fever. The disease appeared two months after the completion of inoculations in one instance, and in the remaining three patients the development of scarlet fever postdated the immunization by six or more months.

Owing to a lack of comparable control groups, the observations made on the two series of children immunized against pertussis and scarlet fever obviously justify no attempts to estimate the degree of specific protection that each of the two procedures produced. Nevertheless, the observations demonstrate that inoculations against pertussis and scarlet fever with currently recommended amounts of each material may occasionally fail to produce adequate protection against the disease the immunization in question is specifically supposed to prevent. Our experience in private practice has failed to disclose comparable failures relative to the effectiveness of smallpox vaccination and diphtheria immunization.

Carefully controlled Schick tests applied in 1936 to 3,205 freshmen at Minnesota University with an average age of 18 years yielded positive reactions in 70.1 per cent of the group (table 3). This series of students consisted largely of native residents of Minn.

nesota who had lived in the state during a period in which the local morbidity rate for diphtheria was falling rapidly to relatively low levels. Whether the high incidence of apparent lack of immunity to diphtheria observed for these young adults is evidence that environmental conditions, which normally operate to pro-

duce a naturally acquired immunity, decline when the local prevalence of diphtheria falls is a highly speculative but nevertheless provocative question. Regardless, however, of what the correct answer to this question may be, it seems quite obvious that the practice of administering protective inoculations against diphtheria should be greatly increased.

Evidence which indicates that the immunity to diphtheria produced by inoculating children during a decade characterized by a low local prevalence of the disease tends to persist at a satisfactory level is provided by the results of a survey of 215 Minneapolis children made at the end of an average interval of six and seven-tenths years after they had been rendered negative to the Schick test by inoculations (table 4).

When the follow-up tests were read on the fourth day after their application, 14.9 per cent of the children presented some degree of erythema (table 4). Since control (Moloney) tests were not used, it was impossible to determine whether these erythematous responses indicated a loss of immunity or the presence of a mild degree of sensitivity produced by previous inoculations.

Of greater significance is the observation that 85.1 per cent of the group of 215 adequately immunized children failed to react to Schick tests applied at the end of an average postinoculation period of six and six-tenths years. This fact is interpreted as evidence that the immunity to diphtheria produced in children by inoculations administered during an era characterized by a low morbidity rate for diphtheria usually persists for several years at a satisfactory level. Apparently the retention of an adequate artificially induced protection against diphtheria seems to be largely independent of how the incidence of the disease is shifting in the local environment. If this speculation is correct, diphtheria immunization doubtlessly will supply present and future needs for the specific protection it confers.

Although tuberculosis is a preventable disease, its control is nevertheless difficult. Since the development of a vaccine capable of producing an effective and sustained immunity to tuberculosis probably will remain an experimental problem for many years, the eradication

of this communicable disease doubtless will long continue to be contingent on the prevention of infection with virulent tubercle bacilli. In view of these probabilities, a brief consideration of what perpetuates tuberculosis in man seems to be appropriate.

The first evidence presented here on this point was provided by a tuberculin-sensitive patient who had extensive bilateral pulmonary infiltrations in 1926. The subsequent spontaneous resolution of these lesions, which led ultimately to their reduction to relatively trivial calcified deposits, serves to identify the antecedent infiltrations as examples of the pneumonic stage of tuberculosis of first infection. During the fifth post-infection year, tuberculosis of the lumbar spine developed. In another instance, x-ray study revealed the presence of well calcified hilus glands and a Ghon tubercle in the left lung of a child who also had tuberculosis of the spine. Similar roentgenographically demonstrable deposits, which were interpreted as visible evidence of antecedent tuberculosis of first infection, were found coexisting with tuberculosis of bones and joints in 70.7 per cent of 123 additional patients. These observations seem to provide an answer to the question: Do antecedent infections with virulent tubercle bacilli prevent the occurrence in man of tuberculosis of bones and joints?

The highly communicable chronic pulmonary tuberculosis of the so-called adult type outranks all other forms of the disease as a cause of death and as a menace to the health of the public. Some of the evidence secured at Lymanhurst relative to the antecedent events that are indispensable for the occurrence in man of this important condition is submitted for consideration.

Follow-up studies in 1933 on one patient who was sensitive to tuberculin in 1928 but had no roentgeno-

Negative	183	85.1	6.6
Grand total	215		6.7

graphically demonstrable primary disease revealed the development of extensive and ultimately fatal pulmonary tuberculosis. Initial study of a second tuberculin-sensitive patient disclosed nothing but well calcified hilus glands on the right side. Ten years later this child had extensive pulmonary tuberculosis throughout the left lung. In a third typical case x-ray study in 1931 dis-

closed a pneumonic appearing infiltration in the mid-lung field of the left lung. This infiltration resolved spontaneously and left a few calcifications in the region of the hilus. During 1935 extensive phthisis was found in the opposite lung.

Mile posts which identify stages in the evolution of pulmonary tuberculosis are occasionally disclosed when extensive disease is present at the time of the first x-ray study. This is illustrated by a patient whose initial roentgenogram of the chest revealed a well calcified Ghon tubercle at the base of the right lung coexisting with far advanced bilateral pulmonary tuberculosis.

The records of these few illustrative cases exemplify the development of chronic pulmonary tuberculosis as it has been observed to occur in many Lymanhurst children who, previous to the appearance of this serious condition, were sensitive to tuberculin but otherwise seemed to be healthy. These observations on children are considered to be on a par with experiments on animals in suggesting the correct answer to the question: Do antecedent primary infections with virulent tubercle bacilli prevent the occurrence in man of the highly contagious chronic pulmonary tuberculosis of the so-called reinfection or adult type?

Instead of attempting to analyze the relationship of primary tuberculosis to various other reinfection forms of the disease, we desire merely to state that sixteen years of follow-up study conducted at Lymanhurst have produced no evidence that an antecedent infection with tubercle bacilli prevents miliary tuberculosis, tuberculous meningitis, chronic pulmonary tuberculosis, osteo-articular tuberculosis or any of the numerous additional important forms of the disease that occur in man. Apparently the primary tuberculous complex fails to prevent these various conditions in almost the same manner that a syphilitic chancre fails to prevent gummas, tabes dorsalis and dementia paralytica.

These observations lead us to believe that the control of tuberculosis is contingent exclusively on taking advantage of the inability of the causative agent of the disease to perpetuate itself and to survive through successive generations of the human race if the transmission of tubercle bacilli from person to person is prevented.

The promotion of comprehensive programs of control designed to identify human disseminators of tubercle bacilli requires the cooperation of physicians engaged in private practice, who obviously are in an excellent position to survey systematically the personnel of numerous household units. As a preliminary step, the physician may employ the tuberculin test for the purpose of quickly and accurately differentiating the infected from the uninfected members of each unit. Subsequently, the search for the open cases of tuberculosis that obviously require segregation can be completed by conducting periodic clinical, laboratory and x-ray examinations of each patient in whom the preliminary step of the survey disclosed infection.

If this preferred method of thoroughly canvassing the household cannot be financed, there is the economical alternative not only of temporarily deferring x-ray studies and other relatively expensive examinations in instances in which the preliminary tuberculin tests have demonstrated a failure of infected parents to contaminate their respective children, but also of continuing this policy as long as periodic retestings show that infections are not spreading to previously uncontaminated members of the household. According to this plan the

results of initial and follow-up surveys with tuberculin tests are relied on as providing dependable evidence that no open case of tuberculosis is present in the unit concerned. This scheme automatically concentrates the more expensive methods of examination where their use is indispensable, namely, on the tuberculin sensitive members of units in which infected children are present or in which contaminations obviously are spreading. It used judiciously in conjunction with the preferred plan of thoroughly canvassing households, the economical method for detecting homes in which previously unrecognized human disseminators of tubercle bacilli are present materially augments the scope of surveys conducted in private practice without the aid of special subsidies.

The effective control of bovine tuberculosis accomplished by the American veterinarians, who started in 1920 with herds thoroughly accredited only in the District of Columbia and succeeded during the next two decades in accrediting the herds of practically all states in the Union, suggests that the promotion of a comprehensive program designed to prevent the spread of tubercle bacilli from person to person should have a similar effect on tuberculosis of human origin. Consequently, physicians engaged in private practice are urged to conduct individual tuberculosis surveys on the household units under their care. These surveys, combined with those being sponsored by different clinics and organizations, doubtless should accelerate the eradication of the human source of infection, which now is almost exclusively responsible for the occurrence of tuberculosis in successive generations of man.

78 South Ninth Street

ABSTRACT OF DISCUSSION

DR. LEE FORREST HILL, Des Moines, Iowa. The plan presented for carrying out immunization procedures is important if one is to apply the protective inoculations at the optimum time for greatest effectiveness. It enables one to supplant haphazard programs with definite ones based on known facts concerning the individual peculiarities of the various disease processes. It was not the purpose of the authors to include whooping cough and scarlet fever immunizations among those of unquestioned reliability but rather to indicate the age period when they should be given. Certainly the present evidence points to the need of considerably more support before one can accept either whooping cough or scarlet fever prevention as procedures that can be recommended by the physician as being on the same level of effectiveness with diphtheria and smallpox. My experience with Sauer's vaccine has not been as favorable as the authors'. Of about 200 children given the vaccine, five have subsequently developed whooping cough. While such results should not condemn the method, they have caused me to be cautious in what I promise parents. In considering the desirable age for administering whooping cough vaccine one has in mind the high mortality of this disease in infancy, but on the other hand one remembers the experience of Madsen, who reported one or two fatalities in very young infants, following the inoculations. The suggested age by the authors of 6 months would seem fairly satisfactory. Present knowledge indicates that the optimum age for diphtheria immunization is in the neighborhood of the ninth month. In those situations in which no immunizations have been carried out before this age period has been reached and the question arises as to which should be given first, my own opinion is that preference should always be given to those of proved value, such as diphtheria and smallpox. The proposal of Drs. Stewart and Platou to give the whooping cough and scarlet fever immunizations in a greater number of small doses seems desirable if uncomfortable reactions are to be avoided. I am glad to see the authors include tuberculosis among the list of acute communicable diseases. The epidemiologic features of tuberculosis have not

received the attention they deserve. The tuberculin test is undoubtedly being used much more extensively, but still not to the limit of its possibilities. The plan proposed of regarding the family in which tuberculosis exists in any form as a unit for continuous study with the thought uppermost in mind of detecting the spreader of bacilli or of instituting treatment to prevent future spreading of bacilli is the plan which at the present offers the greatest promise of future control of tuberculosis.

DR. HENRY T. PRICE, Pittsburgh. There are two obvious ways of lessening the local and systemic reactions of immunization procedures: first, modifying the toxin, as in diphtheria toxoid; second, giving the inoculation during the first year of life when the infant's response to the inoculation is mild. The latter method has been less frequently chosen, and one views with interest Stewart and Platou's experiments with pertussis immunization during the first three months of life. It is not clear whether the refractory state in the young infant to certain infections is due to passive immunity transmitted from the mother, to absence of skin reaction, or to an inherent resistance brought about by a unique chemical organization, of the first growth period of life. My observations, concerned mainly with immunization against scarlet fever with a chemical fraction of *Streptococcus scarlatinae*, confirm the observations of Stewart and Platou regarding the decreased reaction during the first and early years of life. A total of 3,000 children in three public school districts tested for susceptibility to scarlet fever showed an average of 50 per cent positive reactors. These reactors have been immunized, two of these groups have been followed for one year, the third group for two years. Practically no systemic reactions have occurred, about half of the older children and adults developed soreness at the site of the injection. Children under 7 years of age received four injections, older children received five. Immunization developed slowly, 70 per cent tested became negative at the end of one year and the remaining 30 per cent required two years to become negative. The various factors responsible for delaying the development of immunity in certain individuals are not at present known, although allergy seems to be an important one. An interesting observation was the almost complete elimination of scarlet fever from a community where a considerable part, but not all, of the susceptible individuals were immunized. It remains to be seen whether the period of protection induced by the immunization against scarlet fever with modified material will be shortened, as is the case with diphtheria toxoid. Artificially produced immunity is probably never absolute and is modified by many factors, among which are general resistance, allergy and race.

DR. HERMAN SCHWARZ, New York. I should like to say a word about the importance of the tuberculin test. For the last seventeen years I have done a test on my children twice a year. I have always been at a loss to understand why even the pediatricians haven't made use of it. I am delighted that the authors brought that up today. It is so simple. When I tried to introduce it into the private school where my children go, I was unable to do it. My old colleagues in New York and elsewhere have said "What's the use?" Of course, when one has domestic servants it is increasingly important. If one of my children should show a positive tuberculin test, I would look for the sources in my household. If we do anything as children specialists, I believe we should certainly popularize this test. As the authors have so well said, as we have done for the animal we should do for man.

DR. CLIFFORD D. SWEET, Oakland, Calif. I want to commend Drs. Stewart and Platou for emphasizing the importance of using the tuberculin test. Every new patient should have a carefully done tuberculin test. All patients who have an annual health examination in the pediatrician's office should have a tuberculin test. I am not going to wait for a child in my family to develop a positive tuberculin test before I examine the servants. I will not take a servant into my house unless that servant first has a physical examination, including a roentgenogram of the chest, and I so advise the parents of the children whom I take care of. When a child has a positive tuberculin test I agree thoroughly that his environment should be searched carefully, including especially the aging grandparents who per-

haps visited six months earlier. I think that three doses of toxoid for immunizing the child against diphtheria are much better than two doses. My own experience is that 1 year of age is a better time than 6 months or even 9 months. I am quite certain that one should not promise parents anything from immunization against whooping cough with Sauer's vaccine, although I am carrying it out as a matter of routine at 8 months of age, saying to the parent that if it will protect the child, even in part, for one year, it is well worth doing. Performed in divided doses, as Drs. Stewart and Platou have indicated, it did not give unfavorable reactions. One should not attempt to do too many immunizing procedures to the infant during the first year of his life. I think that smallpox, diphtheria and whooping cough are enough. Typhoid immunization doesn't last above two years or is not to be trusted, and in the ordinary community, with its usual safeguards, and with pasteurized milk, I think we may let typhoid go. I don't think we should attempt to immunize all children against scarlet fever. I have not yet immunized my first one. I think the rash is an allergic reaction. We are probably protecting them from the rash, while we still leave them susceptible to the infection and all the complications of scarlet fever.

DR. PERCIVAL NICHOLSON, Ardmore, Pa. I take exception to Dr. Sweet's remarks and believe active immunization against scarlet fever practical and of distinct value. In the Philadelphia Hospital for Contagious Diseases in a ten year period (1926-1936) 615 nurses were subjected to the Dick test and positive reactors were given active immunization, none developed scarlet fever. Immunization was discontinued for fourteen months, and twelve nurses developed scarlet fever. After resumption there were no further cases. In nine years (1927-1936) other Philadelphia hospitals not using active immunization sent to the Hospital for Contagious Diseases 196 nurses with scarlet fever. They spent 6,215 days, or seventeen years, in the wards and cost Philadelphia about \$48,000. In a three year period I have Dick tested and immunized 257 children in private practice. Over twenty-five have had known exposure to active scarlet fever with no evidence of infection. Even the mildest case of scarlet fever is often followed by severe renal, cardiac or auditory complications. In a private school epidemic, fifteen boys had scarlet fever. In one of the mildest cases, diagnosed only by throat culture, a severe heart lesion developed and the boy was out of school 127 days. Severe kidney lesions developed in two other supposedly mild cases. A mastoiditis in one necessitated a mastoidectomy, another patient had cervical and mesentery adenitis and later acute appendicitis with an appendectomy. Whether allergic or not, immunization with Dick toxin will prevent clinical scarlet fever with a rash. Quarantine causes a large economic loss, in this private school a loss of 2,000 school days. By preventing clinical scarlet fever one can treat streptococcal infections and allow children to return to school when throat cultures are negative, without prolonged and unnecessary quarantine. However, active immunization probably not only prevents clinical scarlet fever but also the more serious complications of ear, heart and kidney. In the Vineland (N. J.) school for the feeble-minded, during an epidemic of scarlet fever, convalescent serum was used but in ten days new cases developed and there was a 60 per cent positive throat culture rate. Active immunization with Dick toxin terminated the epidemic after the third dose. This rapid termination of epidemics has occurred in several other institutions. If patients are given large amounts of orange juice with dextrose before injections of Dick toxin, and several hours rest afterward, reactions will be very few and mild.

DR. C. A. STEWART, Minneapolis. I should like to say in conclusion that statements relative to the immunity produced by pertussis vaccine should be very conservative. Need for an effective vaccine that prevents pertussis and scarlet fever exists and I trust that continued progress in research will develop new immunizing materials superior to those we now have. Relative to tuberculosis may I add that when testing children in private practice I also apply the Mantoux test to parents. This policy yields information relative to the entire family. Studies indicate tentatively that about one household unit in five in Minneapolis is certified without a single positive reaction in the entire unit.

OBSERVATIONS ON THE MODE OF ACTION OF SULFANILAMIDE

ELEANOR A. BLISS, ScD

AND

PERRIN H. LONG, MD

Fellow and Associate in Medicine, Respectively the Johns Hopkins School of Medicine

BALTIMORE

Domagk¹ reported in his original communication on the use of the hydrochloride of 4 sulfamido-2', 4' diamino azo-benzene in the treatment of experimental streptococcal infections of mice that phagocytosis of the streptococci by the leukocytes played an important rôle in clearing the tissues of streptococci in the treated mice. Levaditi and Vaisman² soon afterward advanced the hypothesis (without much experimental evidence) that this chemical interfered with capsule formation, thus rendering the streptococci susceptible to phagocytosis. The Trefouels and their associates³ made the important observation in 1935 that para-aminobenzenesulfonamide was active as a therapeutic agent in curing mice of experimental streptococcal infections. Fournneau and his collaborators⁴ first reported that para-aminobenzenesulfonamide had a bacteriostatic effect on the growth of certain molds.

Colebrook and Kenny⁵ stated that the hydrochloride of 4 sulfamido-2', 4' diamino azo-benzene and the disodium salt of 4 sulfamido-phenyl-2'-azo-7'-acetyl-amino-1'-hydroxynaphthalene-3', 6'-disulfonic acid possessed practically no bacteriostatic effects in vitro but that the serums of patients treated with these dyes possessed bacteriostatic qualities against hemolytic streptococci. In our preliminary communications⁶ we noted the bacteriostatic effect of sulfanilamide in vitro on hemolytic streptococci and suggested that the therapeutic dye compounds might be activated in vivo by reduction. This explanation was arrived at independently by Colebrook and his associates⁷ and by Fuller⁸. Colebrook and his associates⁷ further concluded, on the basis of in vitro tests with whole blood and serum, that the blood and serum of patients treated with sulfanilamide showed bactericidal as well as bacteriostatic qualities. Rosenthal⁹ reported that sulfanilamide was bactericidal for pneumococci.

In a subsequent report we¹⁰ discounted, on the basis of our observations up to that time, the role of bac-

teriostatics in vivo, and, while concluding that the sulfanilamide must act on the micro organism and not on the leukocytes, we were unable to explain the onset of the phagocytosis that was evident in the peritoneal exudates of the treated animals.

Recently, Gross and his associates¹¹ have reported that they are not inclined to believe that the phagocytic activity of the polymorphonuclear leukocytes and monocytes is of importance in controlling experimental streptococcal infections in mice treated with sulfanilamide.

In this present report we shall give experimental observations on the mode of action of sulfanilamide in hemolytic streptococcal and other experimental infections and in view of new data, we must reinterpret our former observations concerning the role of phagocytosis in experimental infections that were treated with sulfanilamide.

METHODS

The following methods were employed in the experimental studies. The cultures of beta hemolytic streptococci used for inoculating mice were twelve to fourteen hour old blood broth cultures from the heart's blood of a mouse which had succumbed to the streptococcal infection. The cultures were incubated at 37°C. Dilutions were always made in beef infusion broth, a different pipet being used for each dilution. Peritoneal exudate was obtained by paracentesis of the mouse's abdomen with sterile glass capillaries. Then films were made of the exudate and these films stained with Wayson's stain and Wright's stain. Capsules were demonstrated by mixing a drop of exudate with a drop of a 2 per cent watery solution of congo red and spreading the mixture with a cigaret paper. The colonial type was determined by inoculating the exudate on the moist surface of freshly prepared chocolate blood-agar plates and incubating the plates for sixteen hours at 37°C. The mouse virulence of the exudate was determined by mixing one drop of the peritoneal exudate with 1 cc of sterile broth and inoculating the whole amount into the peritoneum of a normal mouse.

EXPERIMENTAL OBSERVATIONS

As has already been stated, there is little evidence that sulfanilamide is bactericidal (in the sense of being an antiseptic) in vitro. In table 1 are the results of numerous tests in which a known number of beta hemolytic streptococci were exposed to 0.1 per cent sulfanilamide concentrations in broth or serum broth at icebox temperatures ($\pm 4^\circ\text{C}$) for varying periods of time. The cultures from which the dilutions of the beta hemolytic streptococci were prepared were actively growing twelve to fourteen hour cultures. As will be noted in table 1, there was no evidence that sulfanilamide exerted any bactericidal effect on beta hemolytic streptococci under the conditions that have just been outlined.

Further experiments designed to test the bactericidal effect of sulfanilamide in vitro are shown in table 2. In these experiments the centrifuged sediment from 10 cc of a twenty-four hour beef infusion broth culture was suspended in Tyrode's solution and the same solution to which 0.1 per cent sulfanilamide had been added. After the bacterial population of these solutions had been determined by blood agar dilution plate the suspensions were incubated for twenty hours at 37°C.

C and the bacterial population of the suspensions were again determined. No evidence was obtained that the death rate of the bacteria suspended in Tyrode's solution was hastened by the addition of sulfanilamide.

Finally, the bactericidal effect of the serums of human beings before and after treatment with sulfanilamide was tested against certain strains of beta hemolytic streptococci *in vitro*. These tests were performed by inoculating 1 cc of the various serums with a loopful of a 1:5,000 dilution (in beef infusion broth) of 9 to 14 hour old cultures of beta hemolytic streptococci. After twenty-four and forty-eight hours of incubation at 37 C, 0.25 cc of each serum was implanted in a poured blood agar plate and after incubation a colonial count was made. In addition, the sulfanilamide content of each serum was determined by the method of Marshall and his associates¹².

It was noted in the serums taken before treatment that either free growth, partial inhibition of growth or killing took place in certain instances. This was in entire conformity with the recently observed Tillett phenomenon¹³. In the serums containing sulfanilamide, a partial inhibition of growth at the end of twenty-four hours' incubation was the rule, although in certain serums this was not noted. This particular inhibition of growth (bacteriostasis) of hemolytic streptococci in mediums containing sulfanilamide has been previously described by us and was to be expected. After forty-eight hours' incubation at 37 C the sulfanilamide containing serums showed, as a rule, fewer organisms than did the control serums taken before treatment. This may be evidence of a very feeble antiseptic action of the sulfanilamide or may be due to the exhaustion of the medium. Which of these factors operated in this instance cannot be determined. However, the evidence is clear that the serums of patients treated with sulfanilamide exert little, if any, bactericidal effect on beta hemolytic streptococci *in vitro*.

In an earlier report we^{9a} stated that "phagocytosis of the streptococci by the polymorphonuclear leukocytes plays a paramount role in controlling the infection in the early stages of treatment and that later the monocytes join in this phenomenon." All of our subsequent observations have seemed to confirm the belief that in treated mice the streptococci are eradicated by the phagocytes.

We have repeatedly studied this factor, and in tables 4, 5 and 6 examples of the sequence of changes occurring in the peritoneal exudates of treated and untreated mice are portrayed. In the experiments outlined in table 4, treatment was started ten hours after infection had been initiated by the intraperitoneal injection of 1,000 minimum lethal doses of strain C203. Just before therapy was begun, the peritoneal exudates of the infected mice showed little phagocytosis and varying numbers of free hemolytic streptococci. Seven hours later the peritoneal exudates of the treated group showed many streptococci and marked phagocytosis, while the peritoneal exudates of the control mice in three instances showed myriads of streptococci and no phagocytosis. In the other control mice a moderate degree of phagocytosis was present, but in none was it comparable to that in the treated animals. Fourteen hours after treatment had been initiated, five of the six treated mice showed a decrease in the streptococci

present in the exudate and an appreciable amount of phagocytosis. By that time all the control mice were dead.

Table 5 shows examples of the changes that occur when the infecting dose is not overwhelming (as in the previous experiment) and when treatment is commenced at an earlier period. Under these conditions phagocytosis again seems to be definitely more accentuated in the treated mice than in the controls. Finally, in table 6 are observations made at frequent intervals on the peritoneal exudates of untreated mice. In each instance an increase in the number of free streptococci was noted as time went on, and, while varying degrees of phagocytosis were observed, it never approached the degree seen in the peritoneal exudates of treated mice.

It is important to note at this point that, beginning about twelve hours after infection, there is a progressive decrease in the number of potential phagocytes in the exudate of the untreated animals due, apparently, to the toxic effects of the infectious process. Often, for a few hours before death, only shadow forms and badly damaged leukocytes can be seen. Hence, in untreated mice there is an absolute as well as a relative decrease in phagocytosis as compared with treated mice.

We were interested in determining, if possible, just what happened to the hemolytic streptococci in the peritoneal exudates of treated mice. Table 7 is an example of the effect of treatment on the colonial type, the mouse virulence, capsules, phagocytosis and rate of multiplication of hemolytic streptococci in the peritoneal exudate of treated mice that had been infected by the intraperitoneal route with 100 minimum lethal doses of C203 eleven hours before the observations and treatment were commenced. As will be noted, there was no change in colonial type, the mouse killing power of a drop of peritoneal exudate remained unimpaired, and capsules persisted as long as the mouse survived. This was also true of untreated control mice. It is interesting that while no free cocci were demonstrable and the cultures were sterile from the exudate of mouse 4 from the thirty-sixth to the ninety-fifth hour, a drop of exudate regularly killed normal mice when injected into the peritoneal cavity. The effects of treatment on the multiplication of the streptococci *in vivo* and their phagocytosis by the cells in the peritoneal exudate followed the same pattern as has been previously described. No definite conclusions can be drawn from the experiments, but we feel that at least they present evidence that radical changes in certain characteristics of the mouse-virulent streptococcus are not brought about by treatment with sulfanilamide.

Thus, as a result of our observations on the fate of beta hemolytic streptococci in the peritoneal exudates of experimentally infected mice which have been treated with sulfanilamide, we can only state that an increase in phagocytosis and a decrease in the free cocci has been noted. It is impossible to say as yet whether this effect of sulfanilamide is primarily on the hemolytic streptococci or on the phagocytes.

Recently we¹¹ have noted that sulfanilamide has a curative effect in mice infected with *Clostridium welchii*. Studies made on the peritoneal exudates of treated and untreated mice have been of great interest. The strain of *Clostridium welchii* which we used to infect mice killed 90 per cent of untreated mice within a few

¹² Marshall E. K. Jr Emerson Kendall Jr and Cutting W. C. Para Aminobenzenesulfonamide J. A. M. A. 108:953 (March 20) 1937.

about fifty cases, and in every instance the lesion has stopped spreading within sixteen hours after the administration of sulfanilamide. Of course, we feel that if one wants to get marked clinical effects one must give the large doses, which we have been giving in Baltimore. With regard to streptococcal sore throat, all I can say is that it seems to be effective. It is very difficult, of course, to set up statistical studies regarding the effect of any drug on streptococcal sore throat. However, in cases that have gone on to a definite peritonsillar involvement, we have noted that sometimes the swelling and edema disappear with startling rapidity when adequate amounts of sulfanilamide have been given. I want to conclude by begging that care be taken in the use of sulfanilamide. Otherwise the administration of sulfanilamide is going to result in many cases of hemolytic anemia and agranulocytosis with fatalities.

THE VALUE OF NEPHROSTOMY AND DECAPSULATION IN ANURIA

GEORGE R. LIVERMORE, M.D.

MEMPHIS, TENN.

In a paper read before the American Association of Genito-Urinary Surgeons in May 1933 I stressed the value of nephrostomy in anuria and reported four cases in which I was successful both in establishing diuresis and in saving life. I also reported a case of anuria due to poisoning with mercury bichloride from Dr. W. H. McNeill's service at Bellevue Hospital in New York City in which the treatment had the same happy result. I now wish to present another successful result, in a case of anuria due to poisoning with saponated solution of cresol.

In 1914 I¹ reported a surgical treatment for anuria which consisted of decapsulation, nephrotomy and packing the pelvis through the nephrostomy wound with gauze saturated with 10 per cent ichthammol in glycerin. I now feel that the pack adds nothing that cannot be accomplished by the nephrostomy tube and decapsulation. Having recently used the method in a case of anuria resulting from poisoning with saponated solution of cresol, with complete relief and restoration to health, I think it is of sufficient interest to report in detail.

Cabot, Boyd and I, among others, have reported favorable results from nephrostomy, but I feel that it is such a valuable and life-saving procedure that repetition and reports of cases may bring it to the attention of some members of the profession who are unaware of the great good that it may accomplish. Cases in which it is of especial value are those in which a desperate condition prevails, e.g., anuria following poisoning with phenol or mercury, acute obstruction with sepsis that it would be too hazardous, or very difficult, to relieve by operation, and calculous anuria, especially in patients with only one kidney who are not relieved by drainage with a catheter. In order, therefore, to obtain the best results, it is essential that nephrostomy be done as quickly as possible with paravertebral block supplemented by as little cyclopropane anesthesia as possible.

TECHNIC

The kidney is freed as rapidly as is compatible with safety and good surgical procedure, an incision made 1 cm. posterior to the convex border of the kidney and the finger passed through it into the pelvis. A 33 to 35

F catheter is then placed in the pelvis through the nephrotomy wound and sutured to the parenchyma with No. 2 plain catgut. The catheter should have an opening in the tip and one on each side just above the tip. The kidney is then replaced and the tube is anchored to the skin with silkworm gut. In cases in which the kidney cannot be freed the nephrotomy wound may be made near the convex border or on the post surface of the kidney.

Cabot's method of making an opening in the pelvis of the kidney and passing a U-shaped sound into this opening and out through the convex border at a point that drains the lower calyx is excellent. I believe, however, that the location of the tube makes little difference. If the end with two eyes is placed in the pelvis, because it is the relief of tension due to removal of the capsule and the nephrostomy wound that enables the kidney tubules to function. It is a fact too that, when the ureter is patent, at least as much urine will pass down the ureter to the bladder as is carried off by the tube in the kidney. I have not found it necessary to use a winged or Pezzer catheter and rather hesitate to do so on account of the difficulty of removal.

It is remarkable how well patients progress after bilateral nephrostomy, and they seem to suffer no more than when subjected to a single kidney operation.

Chace and Myers² stated that a patient with 5 mg. of creatinine per hundred cubic centimeters of blood never recovers. In the case here reported the patient had a creatinine content of 7 mg. and practically complete anuria, and nephrostomy and decapsulation were not done till the eighth day following poisoning. As he made a complete recovery, I think the case is worthy of report.

M. L., a white man aged 22, was tall, slender, neurotic and an introvert. He was an only child, pampered and spoiled by the mother. The father had no voice in his management. He had the usual diseases of childhood and typhoid fever when he was 15.

March 24, 1936, at 11 p. m., while on a spree, the patient drank 2½ ounces (75 cc.) of saponated solution of cresol in a high-ball. He was taken by ambulance to the hospital where he was seen in the emergency room by his family physician. He was unconscious, cyanotic and in profound shock. Cardiac stimulants were given and his stomach was lavaged with sodium bicarbonate solution, 1 drachm (4 cc.) to the pint, to which about 2 ounces (60 cc.) of alcohol was added. One half ounce of alcohol in 1 ounce of water was left in the stomach after the lavage. When the patient reached his room his temperature was 100.2 F., pulse rate 140 and respiratory rate 14. Epinephrine, atropine, caffeine, sodium benzoate and digifoline were given at intervals during the night. An air way was introduced and carbon dioxide administered frequently for cyanosis and dyspnea. The patient regained consciousness at 5:30 the next morning, and although his mouth and pharynx were severely burned he drank water and orange juice and ate crushed ice during the day. He vomited many times, and at 9:30 a. m. he voided 12 ounces of dark brown urine and at 1 p. m. 10 ounces more. The urine was acid and cloudy, had a specific gravity of 1.013, showed a 1 plus reaction for albumin, a rare pus cell and no blood cells. By 3 p. m. the patient's mouth and pharynx were so sore and swollen that deglutition became very difficult. There was no urinary output during the night and the following day, but at 1 a. m. on May 27 he voided 4 ounces. May 28 he voided 2 ounces of very dark brown urine. May 29, at 9 p. m., 1 ounce of urine was obtained with catheter. May 30 he voided less than 1 ounce, May 31, 1½ ounces, and June 1, three-fourths ounce.

Read before the Section on Urology at the Eighty-Eighth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1937.
1. Livermore, George R. South M. J. 7:332, 1914.

2. Chace, A. F. and Myers, V. C. The Value of Recent Laboratory Tests in the Diagnosis and Treatment of Nephritis. J. A. M. A. 67:929 (Sept. 23) 1916.

I was called to see the patient at 2 30 p m June 1 and ordered 1,000 cc of Fischer's solution to be given intravenously every eight hours, 15 grains (1 Gm) of theobromine with sodium salicylate every three hours and 250 cc of dextrose and soda solution by rectum every six hours. The urine was dark brown had a specific gravity of 1.024, showed a 4 plus reaction for albumin and contained innumerable pus and blood cells and hyaline and both fine and coarse granular casts. The nonprotein nitrogen content of the blood was 200 mg and the creatinine content 6 mg per hundred cubic centimeters. The blood pressure was 170 systolic and 80 diastolic. As there was no improvement after the treatment described I advised nephrostomy and decapsulation, but consent was not obtained till the morning of June 2.

The operation consisted of bilateral decapsulation and nephrostomy. A half inch incision was made through the cortex to the pelvis of each kidney. A 22 F catheter was placed in each pelvis and sutured to the cortex with plain No 1 catgut and to the skin with silkworm gut. The nephrostomy wound was closed to the catheter with No 1 catgut a piece of fat being placed in the kidney wound to control hemorrhage. A cigaret drain was applied to each nephrostomy wound and the incisions closed to the catheters and drains, the muscles and fascia with chromic gut No 2 and the skin with silkworm gut. Both operations were completed in one hour. Five per cent dextrose in saline solution, 1,000 cc,

The Blood Picture After Operation

Date (June)	Day After Operation	Nonprotein Nitrogen Mg per 100 Cc	Creatinine Mg per 100 Cc	Blood Pressure	
				Systolic	Diastolic
2				172	23
3	1st	233.0	7.0		
4	2d	181.0	7.0		
5	3d	170.0	5.0	270	60
6	4th	150.0	4.5	270	60
7	5th	143.0	4.4	176	60
8				166	50
9				176	60
11	9th	90.0	3.7	160	80
14				142	84
15	13th	77.0	2.7	130	70
20	23d	28.0	2.0	134	70

was given intravenously on the operating table and 1,000 cc of Fischer's solution twelve hours later and one of the solutions was given every twelve hours thereafter for four days and then once daily till the tenth day. One cc of U 20 insulin was given daily for 4 days and then 0.5 cc till the administration of dextrose was discontinued. The blood sugar content was never found to be above 125 mg per hundred cubic centimeters. Proctoclysis with 250 cc of dextrose and soda solution was done every six hours during the first day.

In the first twenty-four hours after operation the urinary output was 742 cc, in the second twenty-four hours 2,130 cc in the third twenty-four hours, 2,760 cc and in the fourth twenty-four hours, 4,000 cc.

June 5 a blood count showed red cells 3,390,000 and hemoglobin 70 per cent, therefore 500 cc blood was given by the citrate method and 90 cc of citrate used instead of 60. June 11 the count showed red cells 3,192,000 and hemoglobin 62 per cent, so another transfusion of 500 cc of citrated blood was given.

On the day of operation June 2 the nonprotein nitrogen content of the blood was 200 mg per hundred cubic centimeters and the creatinine content 6 mg. Subsequent values are shown in the accompanying table.

The temperature varied from 102 to 99.4 F from the operation to June 21. It then fell to normal and remained so. The pulse rate was between 140 and 110 until June 16 and then 90 where it remained till July 15 when it was 78.

On the fourth day after operation the patient had a severe convulsion lasting two minutes and two more within the next thirty minutes. Morphine one fourth grain (0.016 Gm) failed to control so chloroform was given with good effect and the administration of morphine repeated. The patient was put in a mustard bath and then wrapped in warm blankets and good diaphoresis was established. No more convulsions occurred.

The patient continued to improve each day, as shown by his general condition, the blood picture and the urinary output. The urine gradually improved until, on July 20, it was free from albumin, casts and blood and contained only a rare pus cell. The nephrostomy tubes were removed on the fourteenth day after operation, and the wounds were completely healed July 20.

The patient has been working daily for nine months as a clerk in a large wholesale hardware store, has not touched any liquor since the night he entered the hospital, and says he never was in better health than he is at the present time.

Medical Arts Building

ABSTRACT OF DISCUSSION

DR NELSE F OCKERBLIN, Kansas City, Mo. The idea of decapsulation came about perhaps fifty years ago, as a result of theoretical considerations. One was to liberate the kidney from the pressure within the capsule, and the other was to try to get new blood supply to the kidney. Edebohls popularized this method and it had a great vogue for a time and there have been waves of revival of decapsulation from time to time. Just how many of those operated on would recover anyway is a problem of which one is not sure. I think Dr Livermore should be commended on the report of this case and the excellent results obtained. If enough of these cases can be reviewed I believe that some valuable conclusions could be drawn on this subject.

DR A I DOBSON, Richmond, Va. I want to say a word in commending this method of treatment. I have had an opportunity to use it in cases of calculous anuria and in acute fulminating conditions of the kidney in which only one kidney was drained. I feel it is important that Dr Livermore's paper be brought to the attention of internists and men in general practice. In my own service I have on a number of occasions advised and requested the opportunity to do nephrostomy and decapsulation in cases of poisoning in different types of anuria, without the consent of either the family or, most frequently, the doctors who are managing the case. It has been my experience that the internists in my section of the country have little faith in it and fear to submit their patients to such procedure.

DR GEORGE R LIVERMORE, Memphis, Tenn. I think it is an operation that is particularly valuable in certain types of cases. One cannot expect to cure all the cases of poisoning by mercury bichloride and saponated solution of cresol, because the kidney is not the only organ that is damaged. Both the gastro-intestinal tract and the liver come in for a large share of damage and though kidney function is established the patient often dies from other complications. Some years ago Sanford of Cleveland reported two cases of mercury bichloride poisoning successfully treated by this method. It is remarkable that when a nephrostomy and decapsulation are done when the patient has been anuric for some time oftentimes the tube will begin to drip urine even before the patient has returned to his room. I could cite numerous cases in which it has been a life saver in my practice. One patient having bilateral kidney stones and complete anuria from a stone in the right ureter drained 2,000 cc of urine in twenty-four hours following this operation and later I removed the stones from the ureter and both kidneys. Another patient with one kidney came back with complete anuria due to a stricture of the ureter. A catheter could not be passed beyond the stricture in the ureter, but drainage was established through nephrostomy and decapsulation. This patient is alive and well today nine years after her operation, and is still wearing her nephrostomy tube. In such cases the condition of the patient is critical, and most of them will die unless operated on, but if one does a nephrostomy one at least gives them a chance to establish drainage which if successful will often bring about happy results.

Healers and Emotional Strain—It is well known by every intelligent person today, layman as well as physician, that many ailments are caused or modified by emotional strain and many forms of treatment by various sorts of healers are successfully practiced on the basis of this knowledge.—Robinson G Canby, The Relation of Emotional Strain to Illness, *Ann Int Med* 11:345 (Aug) 1937.

Clinical Notes, Suggestions and New Instruments

REMOVAL OF POWDER TATTOO BY MINOR SURGERY

H. C. L. LINDSAY, M.D., PASADENA, CALIF.

Methods of removing gun powder are fairly efficient, it is vastly more difficult to free the skin from powder stains or tattoo marks.

The first complete success in the treatment of such a case that I witnessed was carried out on myself by Capt. James M. Taylor, R. A. M. C. I received a black powder blast in the face. The shot was fired at close range and thus the powder penetrated the tissues to considerable depths in various places.

The removal of the powder grains commenced the same day and proceeded, with the exception of rest periods for three days. Antiseptic compresses were applied at night and the following day the work of removal of powder was renewed. Serum accumulated around individual grains of powder. These were difficult to remove the first day, but the serum seemed to facilitate their removal the following days. Inside of three days every grain of powder had been eradicated from the skin and within two weeks no signs of disfigurement were visible.

Dr. Taylor used a Hagedorn needle, firmly held in a small needle holder, for prying out the powder or scraping out any stain. He kept the part moist during the operation with pure alcohol. This antiseptic did not obscure his field and he used hydrogen peroxide or pressure to stop any undue hemorrhage and oozing of serum from minute cuts.

Until recently this technic for removal of powder grains and stains had proved a satisfactory procedure. However, the newer powders are finer grained and have higher explosive coefficients than formerly. They actually penetrate deeper into the skin and leave more tattoo marks. Not infrequently the powder particles, dust or stain are driven right into the underlying muscles. It is necessary to go deeper for these pieces, which show through the skin even though they do go deep.

No very great difficulty is experienced in removing these deeper particles of stain or powder if a Bard-Parker cataract

this portion within the area of the horseshoe like cut by means of the fine splinter forceps to steady it while the cutting is done on the far side of the area and the underneath is completed. Even with a sharp knife, one must allow for some give to the tissue and on this account a slightly wider cut is made. Otherwise minute specks are apt to be missed on this far edge.

It is a good plan to remove all the powder grains at first and the stains at subsequent sittings. Most large areas can be divided up into numerous smaller areas, each bounded by healthy unaffected skin. Removal of areas of tissue or skin

Fig. 2—End result of removal of powder tattoo from the skin.

less than the surface size of an ordinary biopsy punch is attended by but little, if any, disfigurement. Ordinarily no anesthetic is required, but a clear, mild antiseptic is important. Chloral hydrate dissolved in pure ethyl alcohol is suitable for this purpose. The delicate eye knife speedily dulls during use and it is necessary to change blades often in order to do good work and especially to prevent pain.

It is seldom indeed that a suture is required to close a wound. The finest linen is most satisfactory for sewing the skin when necessary but should be removed within three days. Fish-line adhesive strips are of value to hold parts together. Very thin strips of adhesive plaster such as will retain parts in position and still allow exudation to take place between strips may be used.

The after-dressing is simple. The parts are covered with bismuth formic iodide powder and then covered lightly with gauze held in place by adhesive plaster if the lesions are on the body. If only the face is involved I prefer to cover the area with an antiseptic powder and leave it exposed to the air as much as possible. However, exigencies make this impracticable sometimes, more especially in ambulatory cases in which predicament I use the same technic as mentioned for the body.

REPORT OF CASE

M. B., a youth aged 20, single, an American college student, had had excellent general health with the exception that there was a scar on his neck from the removal of tuberculous glands in his early youth. During experiments with an especially finely pulverized high explosive gun powder, the cannon used for the experiments was demolished by an explosion. Powder grains and stains were blown into the patient's face, including nose, lips, tongue, ears and chest but none into the eye. The powder grains were mostly removed by surgeons and the patient was referred to me for removal of the powder stains. This was accomplished by the technic described. The explosion occurred Feb. 14, 1935 and the last of the stain was removed by April 14, 1935.

509 First Trust Building

Fig. 1—Disfiguring powder stains in the skin of the face before their removal by minor surgery.

knife is used for cutting them out. The smallest size splinter forceps is useful in removing loosened specks. Thus having selected a small tattoo spot to be removed the operator renders the area as aseptic as possible and puts tension on the skin with one hand while he cuts carefully around the tattooed powder spot to a depth slightly deeper than the powder stain has penetrated. The blade must be new and keen. When two thirds of the circle has been completed it is advisable to seize

CHEMICAL, PHARMACOLOGIC, PATHOLOGIC AND
NECROPSY REPORTS, PRELIMINARY TOXICITY
REPORTS ON DIETHYLENE GLYCOL AND
SULFANILAMIDE

I

INTRODUCTION

On Monday, October 11, telegrams were received from Dr James Stevenson, president of the Tulsa County Medical Society, and from the Springer Clinic of Tulsa, stating that six deaths had occurred following the administration of Elixir of Sulfanilamide-Massengill, all cases having in common the pathologic condition of complete anuria. The telegrams inquired concerning the composition of the Elixir of Sulfanilamide-Massengill. In response, information was telegraphed that no product of the S E Massengill Company stands accepted by the Council on Pharmacy and Chemistry and that the Council had recognized no solution of sulfanilamide. The reason for the latter statement is that the Council is not in position to accept a solution of sulfanilamide until there is adequate evidence that it is both stable and does not contain toxic material in the doses recommended. The A M A Chemical Laboratory immediately sent for specimens of Elixir of Sulfanilamide-Massengill. Two specimens were received from Tulsa, Okla., of the same solution which, it was stated, had been given to patients. A telegram was sent to the S E Massengill Company asking for the composition of the product. The firm gave the composition with the request that it be accepted confidentially. With this clue the Laboratory immediately tested the first preparation that was received. Information was telegraphed to Dr H A Ruprecht of the Springer Clinic of Tulsa, suggesting the presence of diethylene glycol as the causative factor, the presence of which was confirmed by the Laboratory in the specimens examined. Original specimens were also obtained on the open market in Tulsa and a gallon of the elixir was ordered from the manufacturer. This was shipped promptly. Preliminary animal experiments were also made which indicated diethylene glycol as the toxic agent. A report of deaths in East St Louis Ill., was obtained from Dr O E Hagebusch, pathologist at St Louis. The composition of several specimens of Elixir of Sulfanilamide-Massengill appeared to be the same, the number of deaths in Tulsa had increased and reports from St Louis of additional deaths indicated that the episode was not simply one of local character. The editor of THE JOURNAL then released a general warning to the public through the daily papers and over the radio. This warning was issued Monday, October 18, based on the editorial

which appeared in the October 23 issue of THE JOURNAL, at the earliest possible moment after the facts were established.

Since then the headquarters group of the American Medical Association has had much assistance and cooperation from Dr E M K Geiling and Dr Paul R Cannon of the University of Chicago, and Dr J Howard Brown, Dr Perrin Long and Dr E K Marshall Jr of the Johns Hopkins University, from Mr W G Campbell, chief of the U S Food and Drug Administration, and from Mr J O Clarke, chief of the central division of the U S Food and Drug Administration. By close cooperation between the government and the American Medical Association, reports of deaths were immediately checked by both agencies. Furthermore, the government traced every shipment of Elixir of Sulfanilamide-Massengill

every four hours. Decrease in twenty four
to forty eight hours to 1 or 2 teaspoonfuls
and continue at this dose until recovery

THE S E MASSENGILL COMPANY
Manufacturing Pharmacists
BRISTOL, TENN.-VA.

Label of gallon bottle of Elixir of Sulfanilamide-Massengill. The presence of diethylene glycol was not declared on the label. The dosage recommended should be noted particularly the last statement and continue at this dose until recovery. This phrase is tragically ironical in view of the number of deaths reported.

Wherever any material had been dispensed from a bottle efforts were made to find out to whom it had been administered and to give adequate warning in case the patients were still alive. Acknowledgment is also made to Dr H A Ruprecht and Dr I A Nelson of the Springer Clinic, Tulsa, who furnished the first complete statement of the postmortem examinations, to Dr Darwin B Childs of the Childs Clinic, Tulsa, who forwarded to the A M A Laboratory specimens of the Elixir of Sulfanilamide originally dispensed, and to Dr O E Hagebusch of St Louis for forwarding his results.

II

CHEMICAL EXAMINATION OF ELIXIR OF
SULFANILAMIDE-MASSENGILL

E W SCHOEFFEL, PH D

H R KREIDER, PH D

AND

J B PETERSON, PH D

CHICAGO

A bottle stated to contain Elixir of Sulfanilamide-Massengill, shipped by Dr Darwin B Childs of Tulsa Okla., was submitted to the A M A Chemical Laboratory for examination. The bottle bore the name of the Quaker Drug Company, Rexall Drug Stores of Tulsa.

The bottle contained approximately 50 cc of a reddish somewhat viscous liquid, having an aromatic odor resembling raspberry and anise, a sweet taste and resembling glycerin in general physical character. The specific gravity of the substance was 1.1247 at 23 C. The surface tension was 53.8 dynes per centimeter and the index of refraction was 1.442 at 23 C.¹ A portion of the material was subjected to high vacuum distillation 10⁻⁶ mm (distillation range 70-95 C.) most of the distillate coming over at 75 C. After removal of water the distillate amounted to approximately 72 per cent by volume of a clear, viscous liquid having an index of refraction surface tension and boiling point the same as that for a known specimen of pure diethylene glycol (purchased on the open market). The residue was found to consist of sulfanilamide with small amounts of soluble saccharin, and coloring material such as amarant or similar dye. The odor resembled anise and raspberry. A trace of alcohol was indicated. The residue when examined by microchemical means was found to consist essentially of sulfanilamide.² When the latter was subjected to fractionation and tested by means of the Kofler microchemical melting point apparatus, the fractions were all found to give essentially the same melting point showing that the sulfanilamide had not decomposed in this solution.

Spectrographic examination failed to reveal the presence of such poisonous substances as lead bismuth mercury and arsenic. Quantitative examinations yielded the following:

	By Volume
Diethylene glycol (approximately)	72 per cent ¹
Sulfanilamide (approximately)	10 per cent Weight/Volume
Water (approximately)	15.6 per cent

Chemical examinations were also made on material from the original bottles from Tulsa and on material from a gallon bottle sent by the manufacturer. The resultant figures based on these determinations corresponded closely with the figures given above.

ANALYTICAL PROCEDURE

A measured amount is subjected to high vacuum distillation between 10⁻⁶ or 10⁻⁷ mm of mercury using a fractionation attachment and an all glass ground joint apparatus. The outside bath should not exceed 130 C. The boiling of the liquid begins at room temperature (25) suggesting a small amount of low boiling material. With the rise of the inside thermometer to 30 C the receiver is changed. It contains some of the aromatic flavor substances (probably esters ethanol etc.). Between 30 and 65 C most of the water comes over into the CO₂-acetone cooled receiver. With the use of a Tesla coil the end of the distillation of the water is followed up. As soon as the bright bluish discharge of the hydrogen color disappears the receiver is changed again (temperature of the distillation flask between 45 and 65 C). The thermometer now goes up rapidly to 95 and comes back to 75 C. Again the receiver is changed. At 75 the liquid comes over at a moderate rate. From now on until the end the receiver is changed two times more following the drop in the rate of flow. The distillation is interrupted and the complete dry material is dissolved in as little boiling water as possible. On cooling crystallization sets in. The crystalline mass is triturated with a small amount of ice water and

sucked dry on an outside ice packed Buchner funnel. The liquid gives on evaporation a second yield of crystals. The dry crystalline material containing some of the dye and saccharin is successively extracted with absolute peroxide free ether in a Soxhlet extractor followed by dry absolute amyl alcohol which dissolves the sulfanilamide. The mother liquors of the fractions are evaporated and again recrystallized. All the crystalline fractions are subjected to melting point determinations to check the purity of the sulfanilamide. A decomposition product was obtained at the end of this preliminary report. Further work is in progress.

Conclusions—From the foregoing examination it appears that Elixir of Sulfanilamide-Massengill is essentially a mixture containing approximately 9 to 10 Gm of sulfanilamide dissolved in 100 cc of a solution consisting of diethylene glycol 72 per cent by volume and water 15.6 per cent by volume, to which had been added a small amount of soluble saccharin, coloring such as amarant or similar dye flavoring resembling raspberry and anise, with an extremely small amount of reducing substances. This is in close agreement to the statements of the manufacturer that elixir of sulfanilamide contains 40 grain of sulfanilamide in one ounce of fluid and that the diethylene glycol approaches 75 per cent of the volume.

"SYNTHETIC" ELIXIR

A synthetic preparation was also prepared for the purpose of pharmacologic investigation (this is the material referred to in the reports of Dr E M K Geiling and Dr Paul K Cannon which follow). The synthetic preparation consisted of diethylene glycol 75 per cent by volume, sulfanilamide 10 per cent weight/volume, 0.2 per cent soluble saccharin and 0.2 per cent cochineal, and water to make 100 cc. This product was compared by means of the refractive index and surface tension and specific gravity with (a) the specimen reported on in the foregoing paragraph, (b) the contents of an original pint bottle of Elixir of Sulfanilamide-Massengill and (c) the Elixir of Sulfanilamide-Massengill received directly from the manufacturer. The determinations on the index of refraction specific gravity and surface tension of the several mixtures indicated that they were similar.

Toxicity experiments were carried out on rats, rabbits and dogs on the following substances:

- 1 Pure diethylene glycol
- 2 Pure sulfanilamide
- 3 Elixir of Sulfanilamide-Massengill
- 4 Synthetic elixir of sulfanilamide compounded by the

A M A Chemical Laboratory with pure substances in approximately the same proportions as found in the Massengill elixir (see Chemical Laboratory report).

Our experiments were devised to determine:

- 1 The toxic and lethal doses of each of the substances given in relatively small doses three times daily. This information seems particularly necessary since we were not able to find any data in the literature on this specific point.
- 2 Our experiments were further planned with the hope of being able to reproduce in healthy experimental animals about the same time the clinical and pathologic picture as presented by patients who had taken fatal doses of the Elixir of Sulfanilamide-Massengill.
- 3 Through our experiments we hoped to discern the toxic ingredient in the Massengill elixir.

All animals were healthy adults of both sexes and had free access to food and water. The drugs were administered

1 Compared with water 72 at 22.5 C

2 Sulfanilamide is the name adopted by the Council for the product para-amino-benzene sulfonamide. It was introduced into the United States under the proprietary term Prontosil, a brand of sulfanilamide manufactured by the Winthrop Chemical Company. It should not be confused with Prontosil which may be considered a derivative of sulfanilamide. The word Prontosil unfortunately has been used to describe several substances. Prontosil Album is used in some foreign countries as a proprietary name for sulfanilamide.

3 In the different specimens examined the diethylene glycol content varied from 70 to 75 per cent by volume.

istered by stomach tube in the dosages stated in the tables. The doses selected ranged from apparently non-toxic to surely fatal ones.

From table 1 it will be seen that rats were given diethylene glycol in doses ranging from 0.5 to 4 cc, Elixir of Sulfanilamide-Massengill¹ in doses of from 0.625 to 3 cc, and "synthetic" elixir in doses of from 2.66 to 3 cc per kilogram of body weight three times daily. Most animals receiving the 0.5 cc doses survived for eight days in apparently good health. A few, however, were beginning to show ill effects at the time of writing. About 20 per cent of the animals receiving 1 cc of diethylene glycol or Massengill elixir have died. All animals receiving doses of 2 cc or more of any one of the foregoing died in from two to five days with a terminal anuria. The following is an average clinical picture as seen in rats. After about the fourth dose the animal's fur becomes ruffled, there seems to be increased thirst and diuresis, food is refused, later urine excretion becomes scanty, finally the animal lies on its side, respirations increase in rapidity and depth and anuria sets in, followed by coma and death. Rabbits present essentially the same picture (table 2) but seem to be more sensitive than rats. Dogs too, behave similarly (table 3), but the dosage cannot be accurately determined because the animals vomit after the administration of both diethylene glycol and the elixirs.

Thus far we have found rats and rabbits to be more satisfactory experimental animals for this purpose than dogs.

Experiments were also performed in which sulfanilamide alone was administered by stomach tube to twelve dogs in divided doses of 0.2 Gm per kilogram three times daily, for eight doses. At the end of this period the animals were divided into three equal groups, A, B and C. In group A two animals, dogs 2 and 4, were killed in order to see whether any significant pathologic changes had occurred in the kidneys or liver (see pathologic report). Dog 2 of group A had convulsions after the sixth dose of sulfanilamide alone but recovered. At necropsy no marked liver or kidney injury was seen. Dog 4 had no untoward reactions after administration of the sulfanilamide and showed no striking pathologic change at necropsy. The remaining two are still receiving sulfanilamide in 0.2 Gm doses three times a day and are showing no untoward effects. Group B is receiving Massengill elixir three times daily in doses containing 0.2 Gm of sulfanilamide. Two animals in this group refused food after the second dose, the third dog ate but vomited and the fourth ate and retained the food. Group C is receiving the "synthetic" elixir three times daily in doses containing 0.2 Gm of sulfanilamide. In this group, two dogs refused food, the third ate but little and vomited and the fourth ate and retained food after the second dose. The animals in both groups B and C that refused food are obviously sick at present.

Two additional dogs are receiving diethylene glycol alone in divided doses in an amount comparable to that of the diethylene glycol in the elixirs. One dog began vomiting after the second dose and at present he

is moribund. The other animal began vomiting after the fifth dose and is showing weakness and tremors of the hind legs. Observations on these animals are being continued and a more detailed report will be forthcoming.

A similar experiment was carried out on sixteen rats, all of which received 0.25 Gm per kilogram of sulfanilamide three times daily for seven doses. At the end of this period the animals were divided into four equal groups. Two rats of group 1 were killed for pathologic study and the other two continued on the same treatment of sulfanilamide. Group 2 received 2.5 cc of Elixir of Sulfanilamide-Massengill per kilogram, group 3, 2.5 cc of "synthetic" elixir per kilogram, group 4, 1.9 cc of diethylene glycol per kilogram. All animals were dosed three times daily with the amount per kilogram mentioned. At the end of the fourth day all but three rats in groups 2, 3 and 4

Comment. The rats were kept in cylindrical 12 inch cages in groups of from two to four. These cages were placed on 12 inch funnels and the urine flow was observed in order to determine onset of anuria. Food and water were available at all times.

were dead and these are expected to die on the fifth day. The two rats remaining in group 1 are apparently normal. The clinical course and the gross pathology were essentially similar in all the animals of groups 2, 3 and 4. Anuria was uniformly present. This experiment indicates clearly that it is the diethylene glycol and not the sulfanilamide which is the toxic agent.

A series of rats were also given diethylene glycol and the two elixirs of sulfanilamide in single large amounts of 5, 10 and 15 cc per kilogram by stomach tube. After forty-eight hours all the rats of the 15 cc doses were dead. After three days all the rats on the 10 cc dose of the two elixirs had died, but only one of the three on the diethylene glycol was dead. All rats on the 5 cc dose of the three preparations are seemingly well after five days (they will be killed for pathologic study). This series is too small at present to warrant any definite conclusions. We are, however, prompted to remark that it is possible that if the kidneys and the liver are rapidly injured by a large critical dose (10 cc) of diethylene glycol, the sulfanilamide, especially in large amounts may not be eliminated

¹ In the experiments here reported the doses are larger than those used by human beings. The doses were selected to produce death in animals in about the same time and with the same symptomatology as occurred in the human beings taking the Ma-sengill elixir. Experiments are now in progress with doses lower than 0.5 cc per kilogram given three times daily. These experiments are indicated in view of the fact that Haag and Ambrose reported that rats succumbed when from 5 to 10 per cent of diethylene glycol was administered in the drinking water. Holck and Carlson found that rats succumbed after nine days when 4 per cent of diethylene glycol was given in the drinking water (unpublished data which we are permitted to quote).

or detoxified and may have an injurious action on other tissues. In this way sulfanilamide may then be regarded as having an additive toxic effect. This is suggested as a possible explanation for the fact that some of the rats on the 10 cc amounts of diethylene glycol sur-

vived, while the animals on the elixirs succumbed. Additional experiments will have to be made to settle this point, which we believe to be interesting but in conflict with our view that it is the diethylene glycol which is the important toxic factor (1) in the liver

TABLE 2—Data Obtained from Rabbits Treated Three Times Daily with Various Doses of Diethylene Glycol Elixir of Sulfanilamide-Massengill and Sulfanilamide

Cage No.	Number of Rabbit	Sex	Weight Kg	Drug	Dose per Kg, T i d	Total Dose T i d	Total Number of Doses	Total Amount of Drug Given per Kg	Total Amount of Drug Given	Time of Onset of Symptoms	Symptoms in Order of Appearance	Time of Death
1	1	♀	2.7	Diethylene glycol	0.5 cc	1.5 cc	20	10.0 cc	27.0 cc	72 hrs	Loss of appetite, lassitude, diuresis, increased respiration, symptoms progressed slowly until death	91 hrs
2	2	♀	2.6	Diethylene glycol	1.0 cc	2.6 cc	8	8.0 cc	20.8 cc	40 hrs	Loss of appetite, diuresis, weakness, increased respiration, anuria, coma, death	61 hrs

Comment: All rabbits were kept in well cleaned metabolic cages with water and food available; all doses were given by stomach tube.

TABLE 3—Data Obtained from Dogs Treated Three Times Daily with Diethylene Glycol Elixir of Sulfanilamide-Massengill and Sulfanilamide

Number, Age, Sex and Race of Dog	Weight Kg	Drug	Dose per Kg, T i d	Total Dose T i d	Total Number of Doses	Total Amount of Drug Taken per Kg	Total Amount of Drug Taken	Time of Onset of Symptoms	Symptoms in Order of Appearance	Time of Death	Comment
1* 10 mo male police dog	11.3	Diethylene glycol	1.0 cc	16.9 cc	6	9 cc	101.4 cc	20 hrs	Weakness in hind legs, drunken gait, general lassitude, loss of appetite, increased respiration, diuresis, vomiting, thirst, anuria, coma, muscular tremors, spasms, delirium (barking), death	86 hrs	Kept in cage with free access to food and water; removed to metabolic cage after 67 hr to observe development of anuria
Dogs 1 and 2 were litter mates											
2 10 mo male police dog	11.5	Elixir of sulfanilamide-Massengill	2 cc	23 cc	6	12 cc elixir (9 cc diethylene glycol, 1.2 Gm sulfanilamide)	138 cc	20 hrs	Same as above except death followed convulsions after feeding of milk by stomach tube; autopsy revealed no milk in bronchi	92 hrs	Kept in metabolic cage until death; cage kept clean; animal had free access to food and water
3 20 mo male terrier	8.1	Sulfanilamide	0.2 Gm	1.62 Gm	6	1.2 Gm	9.7 Gm	24 hrs	No loss of appetite; slight general lassitude with rapid and complete recovery after evening administration of sulfanilamide		On the 6th day this dog weighed 10.5 kg., a gain of 1.4 kg. at the beginning of the experiment

* Dr. Julian Flehberger of the Lasker Foundation, the University of Chicago, kindly made the following determinations on the liver of this animal obtained at death:

Chloride	693	Total prot in nonprotein nitrogen	61.7 Gm per liter of serum
Sodium	142 mEq per liter of serum	Albumin	1.2 Gm per liter of serum
Potassium	136 mEq per liter of serum	Globulin	0.21 Gm per liter of serum
A	1.42	Water	0.04 Gm

Note the low p_{H} and the high nonprotein nitrogen and potassium. The changes in blood chemistry are proof of the terminal uremia of this experimental animal. Through the courtesy of Prof. H. Cideon Wells, director of the Otho S. A. Sprague Institute, the University of Chicago, Dr. Carl Markert is cooperating with us in a more detailed study of the fate of diethylene glycol in the animal body and the change in the blood chemistry following ingestion of the drug. Renal and liver function tests will also be carried out on animals treated with diethylene glycol. More complete studies of the rate of elimination of sulfanilamide when administered to the elixir will be carried out.

of Sulfanilamide-Massengill when given to human subjects in the amounts recommended on the label, and also (2) to our experimental animals when given in divided smaller doses. We are planning to repeat the foregoing experiments and also will give a large single amount of diethylene glycol, to be followed by a large single amount of sulfanilamide, accompanied by chemical determinations.

Fig 1—Kidney of rat that ingested 3 cc per kilogram of the synthetic elixir of sulfanilamide three times daily. Killed in a moribund condition after fifty three hours.

Mr. Millberg, of our department, made numerous differential blood counts on animals receiving sulfanilamide alone, Elixir of Sulfanilamide-Massengill "synthetic" elixir, and pure diethylene glycol. He did not find evidence which would indicate agranulocytosis.

We are privileged to say that Dr. Herbert O. Calvery, chief pharmacologist of the Food and Drug Administration, Washington, D. C., and his staff are conducting experiments which are in general accord with our own observations. Their results will be published in detail.

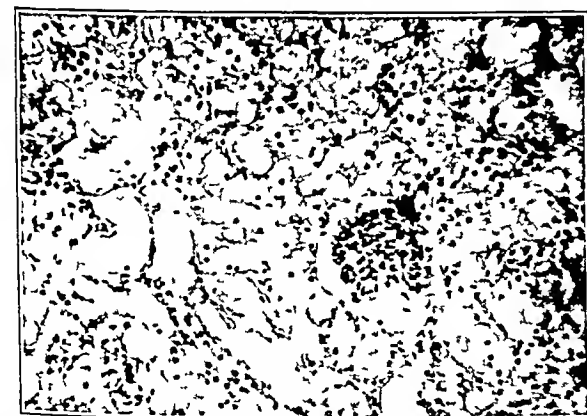

Fig 2—Kidney of rat that ingested 4 cc per kilogram three times daily of a 33 1/3 per cent solution of pure diethylene glycol. Killed in a moribund condition after forty five hours.

There are of course many other ramifications of this problem which have not been touched on in this preliminary report.

SUMMARY AND CONCLUSIONS

1 Our experiments thus far warrant the belief that diethylene glycol is the toxic agent in the Elixir of Sulfanilamide-Massengill examined because experimental animals given diethylene glycol alone exhibit essentially the same clinical course and path-

ologic changes in the kidney and liver as do those treated with similar doses of the Elixir of Sulfanilamide-Massengill or a "synthetic" elixir containing the ingredients and in the same proportion found in the Massengill preparation by analysis. There are, of course, individual and species differences. Thus far we have found the rat and the rabbit more satisfactory subjects than the dog because with them emesis is not a complicating factor.

2 Sulfanilamide alone if given in doses of 0.2 Gm per kilogram three times daily does not prove fatal to rats, rabbits or dogs after eight or more divided doses. However, if sulfanilamide is given in this dosage in the form of Elixir of Sulfanilamide-Massengill or in the "synthetic" elixir, it proves fatal to experimental animals and presents a clinical and pathologic picture closely resembling that reported for the human cases in which death occurred after ingestion of the Massengill elixir.

3 Although animals receiving sulfanilamide in doses of 0.2 Gm per kilogram three times daily did not succumb, several of them had convulsions. Six animals (two dogs and four rats) were killed after

Fig 3—Kidney of dog that ingested 15 cc per kilogram of pure undiluted diethylene glycol three times daily. Died in eighty six hours.

having received eight or more divided doses of the drug. None of them had anuria, nor did they exhibit the renal and hepatic changes found in animals treated with either the Massengill or the "synthetic" elixir (see report of pathologic observations). While we do not believe that the sulfanilamide had any important part in the intoxications resulting from the elixir of sulfanilamide, one must not overlook the possible damage to tissues that may result when sulfanilamide is administered to experimental animals or to human beings with impaired renal function. This point is being investigated.

4 Our experiments emphasize the importance of administering drugs in divided doses to experimental animals when it becomes necessary to know whether or not a drug has cumulative effects. Errors resulting from an oversight of this important pharmacologic principle may be costly in human lives.

We can confirm the finding of Harg and Ambrose—that the ingestion of 15 cc of diethylene glycol per kilogram in a single dose by stomach tube proves fatal to rats. This figure however is no index of the toxic and possible fatal effects of the drug if administered in small divided doses, especially since neither the fate

nor the mechanism of detoxification is known. This substance possibly produces injury to certain cells at a rate faster than the repair processes take place, hence each succeeding dose may be adding insult to injury.

[NOTE—After this article went to press a communication was received from Dr. E. K. Marshall, Jr. too late for inclusion in this report. In this communication he discussed the results in his experiments to date in reference to diethylene glycol, Elixir of Sulfanilamide-Massengill, and sulfanilamide. In general his experiments show that sulfanilamide alone is not responsible for elixir deaths. Large doses of sulfanilamide administered to rats and dogs revealed no functional kidney damage.—P. N. L.]

IV

PATHOLOGIC EFFECTS FOLLOWING THE
INGESTION OF DIETHYLENE GLYCOL
ELIXIR OF SULFANILAMIDE-MAS-
SENGILL, 'SYNTHETIC' ELIXIR
OF SULFANILAMIDE AND
SULFANILAMIDE ALONE

PAUL R. CANNON, M.D.
CHICAGO

Preliminary studies have been made of organs from dogs, rats and rabbits given toxic doses stated to be Elixir of Sulfanilamide-Massengill, "synthetic" elixir of sulfanilamide, and diethylene glycol. The present

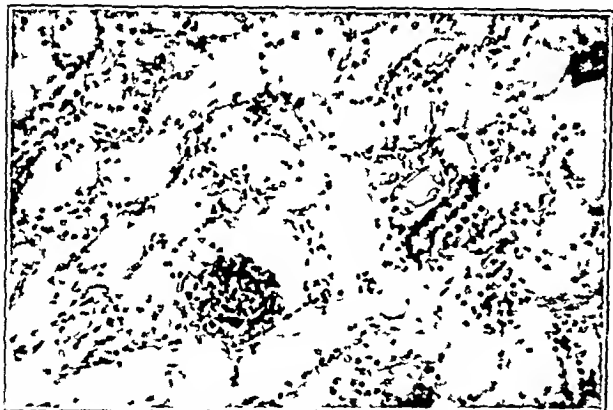

Fig. 4—Kidney of rabbit that ingested 2 cc. per kilogram three times daily of Elixir of Sulfanilamide-Massengill. Killed in a moribund condition after forty-eight hours.

report deals particularly with animals that died or were killed in a moribund state after ingestion of varying amounts of these materials. The general appearances at necropsy were as follows: The kidneys were swollen with tense capsules and bulging bloody surfaces, containing, in some instances, small areas of recent hemorrhage. The cortices were swollen and were usually pale. The heart was dilated and the body as a whole showed marked acute generalized passive congestion. The liver was frequently mottled and bloody but was not greatly enlarged. Pulmonary edema or bronchopneumonia was present. Clear fluid was occasionally present in the peritoneal and pleural cavities. The urine was clear and pale yellow. The gastro-intestinal tract appeared essentially normal. The leptomeningeal veins were distended and the brain was tenser than usual with in some instances an increase in subdural spinal fluid.

From the Department of Pathology, the University of Chicago.
Dr. H. G. Wells gave valuable counsel.

Microscopically, the most marked changes observed thus far have been in the kidneys and liver. In the former there is an intense hydropic degeneration of the epithelium of the convoluted tubules, so marked that the lumens are obliterated and the normal structure is greatly altered. Albumin and hyaline casts are present within the lumens of both convoluted and collecting

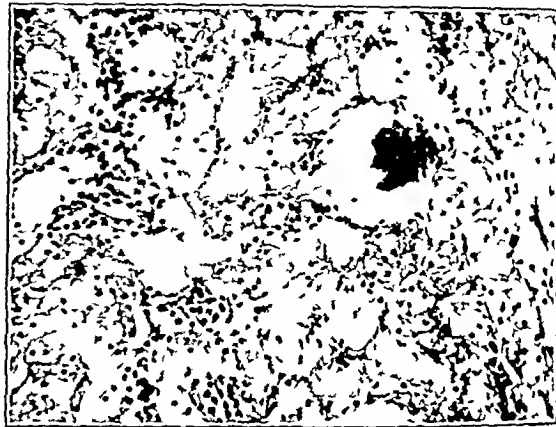

Fig. 5—Kidney of rat that ingested 3 cc. per kilogram three times daily of Elixir of Sulfanilamide-Massengill. Died in fifty-eight hours. Figures 1 to 5 note the hydropic degeneration of epithelium of convoluted tubules, the precipitated albumin in their lumens and the casts. Note also the shrunken but relatively unchanged glomerular tufts and the absence of leukocytic infiltration or vascular damage.

tubules. In some animals the epithelium of the convoluted tubules is necrotic and the cells have disappeared. The collecting tubules are relatively unchanged although fat stains show varying degrees of fatty degeneration. The glomerular tufts are shrunken, although their capillaries are filled with blood. Albumin is also present in many of the glomerular spaces. Leukocytes are inconspicuous. The arteries, arterioles and venules appear normal.

Sections of livers show hydropic degeneration of hepatic cells most marked around the centers of the lobules. Fatty changes are present but are not

Fig. 6—Liver from rat that ingested 4 cc. per kilogram three times daily of pure undiluted diethylene glycol. Died in thirty minutes. Note the hydropic swelling of hepatic cells with their shrunken nuclei and the absence of leukocytic infiltration.

noticeable in the areas of hydropic degeneration at the borders of the hydropic areas. Necrosis of liver cells is not severe, although there is some shrinkage of nuclei, pyknosis and nuclear fragmentation. Leukocytic infiltration is minimal.

A few sections from the lungs show marked congestion, edema and bronchopneumonia. The myocardium

appears essentially normal, although fat stains in some instances show an early fatty degeneration. Other organs have not been examined microscopically as yet, nor have the tissues from animals receiving nonfatal doses of diethylene glycol.

The general picture is that of a severe chemical nephrosis with intracellular edema of most of the epithelial cells of the convoluted tubules, resulting in tubular obstruction by compression and by the intraluminal formation of casts. The pathologic picture is essentially similar in the three species of animals, whether given the Elixir of Sulfanilamide-Massengill, the "synthetic" elixir of sulfanilamide or diethylene glycol alone. This intracellular edema in the kidneys leads to internal disorientation of cells of the convoluted tubules and offers an explanation for the tubular obstruction, anuria, uremia and death. Whether this intracellular change is due to cellular anoxia, with consequent intracellular edema, necrosis, fatty degeneration and cellular desquamation, or whether it is due to hygroscopic properties of diethylene glycol are questions that must await further investigation.

These changes in the kidneys and liver are not due to sulfanilamide alone. We have examined sections from two dogs and four rats given sulfanilamide in divided doses, with toxic manifestations in one dog. The microscopic changes are slight, consisting of moderate fatty degeneration in some of the collecting tubules of the dogs, but minimal in the rats. The livers of both dogs and rats showed no hydropic degeneration and practically no fatty degeneration. There is but little question, therefore, that the severe chemical nephrosis of the dogs, rats and rabbits is due to diethylene glycol alone. We cannot say, however, that under conditions of anuria, with retention of sulfanilamide in the blood stream, some tissue damage by sulfanilamide may not be added to that of diethylene glycol.

We have had the opportunity to examine organs from five persons who died in or near St. Louis after ingestion of Elixir of Sulfanilamide-Massengill. There is a striking similarity between the pathologic changes in the kidneys and livers in these cases and in those of the experimental animals given Elixir of Sulfanilamide-Massengill, the "synthetic" elixir, or diethylene glycol alone. The most striking changes in the human cases are hydropic degeneration of the convoluted tubules with desquamation of epithelium, fatty degeneration, tubular necrosis, hemorrhage, and obstruction of tubules by casts. In one case there is also marked recent infarction with hyaline thrombi in many of the smaller arteries. The lobular hydropic degeneration of hepatic cells is also a prominent feature in the livers from these patients.

The accompanying photomicrographs show the characteristic pathologic changes in the kidneys and livers of rats, dogs and rabbits given Elixir of Sulfanilamide-Massengill, "synthetic" elixir, or diethylene glycol. Figures 1, 2, 3, 4 and 5 show the hydropic degeneration of epithelium of the convoluted tubules, figure 6, the lobular hydropic degeneration of hepatic cells in the liver. These are all from frozen sections of formaldehyde-fixed tissue stained with hematoxylin and eosin with a magnification of 260 diameters.

Conclusion—There is a marked similarity in the pathologic picture in animals and in man following the ingestion in divided doses, toxic to the species, of a lethal amount of Elixir of Sulfanilamide-Massengill in man, or of diethylene glycol, the "synthetic" elixir, or Elixir of Sulfanilamide-Massengill, in animals.

V

CLINICAL AND PATHOLOGIC OBSERVATIONS
BY DR. HOMER A. RUPRECHT AND
DR. I. A. NELSON, TULSA

[The following telegram (October 15) was received at the A. M. A. headquarters from Dr. Homer A. Ruprecht and Dr. I. A. Nelson of the Springer Clinic.]

Total of ten cases. Eight dead. One recovered. One critical. Ages from eleven months to twenty-six years. All received Elixir Sulfanilamide in amounts varying from one-half to seven ounces. Characteristic onset with nausea, vomiting, occasional diarrhea, malaise, later pain over kidney region and abdomen. All developed anuria within two to five days after beginning medication. Indications for the use of sulfanilamide were varied. Nine cases hospitalized. Characteristic physical findings were deep respirations, drowsiness, cutaneous pallor, no cyanosis, slight puffiness of face. Blood pressure normal or slightly elevated, tenderness over kidneys and upper abdomen. Three cases voided small amounts of urine which showed four plus albumin, casts and cells insignificant, no lipoids, no anemia, moderate leukocytosis, non-protein nitrogen progress to near two hundred total, creatinine up to twelve. Patients become progressively comatose. Edema and ascites related to water administration. Death in two to seven days from onset of anuria. Postmortem findings on five cases are yellow tawny color of smooth and not enlarged liver, slight to marked purplish mottling of kidney surfaces, with severe cases showing necrosis limited to superficial portions of cortex. Inconstant peritoneal, pleural and pericardial accumulations of clear straw colored fluid which gels. Rest of viscera insignificant. Microscopic findings show a consistent hydropic tubular nephrosis and central degeneration of liver with cells showing foamy cytoplasm. Sudan stains show (little) fatty degeneration. Consider microscopic picture similar to literature on dioxane, see Navanquez, J. Hyg. vol. 35, pages 540-548. Cannot find evidence of oxalic acid in gross nonmicroscopic tissues nor fluids. No calcium oxalate crystals¹. Have complete viscera from one case in frozen state without fixation. Can send stained sections, portions of fixed or frozen tissues. Federal inspectors arrived today.²

VI

NECROPSIES OF FOUR PATIENTS FOLLOWING
ADMINISTRATION OF ELIXIR OF
SULFANILAMIDE-MASSENGILL

O. E. HAGEBUSCH, M.D.
ST. LOUIS

[Without knowledge of the deaths at Tulsa, Okla., Dr. O. E. Hagebusch sent the following report under date of October 19 for proposed publication in THE JOURNAL.]

In the last several days I have seen four deaths in patients using a product called "Elixir of Sulfanilamide" and sold by Massengill & Company.

¹ A suggestion had been telegraphed to Dr. Ruprecht October 12 that possibly there might be oxalate crystals in case the diethylene glycol contained ethylene glycol.

² In a letter from Dr. Ruprecht of October 11 he stated: "One of the latter two patients had received tablets of sulfanilamide over a period of two weeks without any bad effects and then changed doctors and the second doctor put him on the elixir of sulfanilamide and the typical train of symptoms followed shortly afterward."

Dr. Darwin B. Childs of Tulsa, Okla., in speaking of cases brought to his attention stated: "A patient, a 20 year old adult who had an acute gonorrhea, took a total of 220 grains as represented by 55 teaspoonfuls of the elixir of sulfanilamide. Twenty-four hours after the ingestion of this amount he began to have symptoms of an acute nephritis and forty-eight hours later he was totally anuric. He died four days after receiving the last dose. The clinical picture and autopsy reports of this case closely resemble each of the other cases."

THE CHEMICAL LABORATORY

These patients, all Negroes, were treated by a Dr Weathers of East St Louis, Ill. In all he has given the drug to about thirty people, but of the six people treated recently four are dead and have come to autopsy. One is expected to die at any time, and one may recover.

All have had similar symptoms vomiting and diarrhea, subnormal temperatures, slow respiration, anura, edema of the face, hands and feet, a progressive anura and then death. All four autopsies have shown the same findings, pulmonary edema, marked nephritis with hemorrhage in the

* To the best of our knowledge this list comprises the deaths confirmed by telephone telegraph or other authoritative communication resulting from the administration of Elixir of Sulfanilamide Massengill up to and including October 29. No responsibility however is assumed for its absolute correctness. In some cases the list does not indicate the residence

address of the patient but the address of the attending physician or place of death of the victim. Since this table was set in type two more deaths have been reported bringing the total up to sixty one (November 1)

For Details, See Table

the cortex of the kidney, marked hemorrhage into the pericardium, mucosa of the stomach and duodenum and into the serous surfaces of lung and liver. The liver is pale, edematous and enlarged. Microscopic sections have not as yet been completed.

It was thought that this information should be in the hands of as many physicians as possible, and *THE JOURNAL* was the best means of accomplishing this end.

VII

SURVEY OF DEATHS

Deaths and clues of deaths were reported to the American Medical Association headquarters by various press services, by information received from physicians, and chiefly clues from the Food and Drug Administration. The latter organization placed a tremendous force of inspectors in the field. It obtained a list of approximately 700 shipments from the manufacturer. The inspectors then traced every shipment to its final designation. If the bottle had been opened, they inquired to whom it had been dispensed. It was in this manner that most of the deaths were traced after the original reports from Tulsa and East St. Louis. Each suspected case of death was then checked by the American Medical Association by telephoning or telegraphing physicians or other medical authorities. On an accompanying page is given the list of cities in which deaths occurred, the number of deaths reported to the Association to October 29, and the date on which it has been stated that the patient died. There are many additional reports not confirmed as yet.

Antidote—On October 20 the S. E. Massengill Company sent the following telegram:

Please wire collect by Western Union suggestion for antidote and treatment following use of Elixir Sulfanilamide.

The following reply was sent:

Antidote for Elixir Sulfanilamide-Massengill not known. Treatment presumably symptomatic.

So far as has been determined, there is no known antidote for diethylene glycol poisoning when the drug is administered in amounts comparable to that given the unfortunate victims. Telegrams were sent to Dr. E. J. Marshall, Jr., Dr. W. F. von Oettingen and Dr. P. J. Hanzlik for suggestions. One suggested the use of gastric lavage, calcium therapy orally and intravenously, and symptomatic treatment for nephrosis. Another telegraphed: "Cannot suggest any possible antidote or treatment for patient with Elixir Sulfanilamide poisoning. Fifty per cent dextrose solution with or without sodium bicarbonate intravenously might be tried." Another suggested the use of 20 per cent dextrose solution intravenously to relieve renal edema if possible.

VIII

CONCLUSIONS

1 Elixir of Sulfanilamide-Massengill in the specimens examined was found to consist essentially of sulfanilamide 10 Gm in 100 cc of a solution of approximately 72 per cent diethylene glycol and water 25 per cent by volume, to which had been added flavoring and coloring material.

2 Diethylene glycol in the doses given was the causative agent in deaths.

3 Pathologic results reported herewith both on animal and on man, as well as many reports received by telephone and telegram, indicate that, in cases of

death following the administration of Elixir of Sulfanilamide-Massengill, anuria was present.

4 While sulfanilamide does not appear to have had any appreciable part in the toxicity of this preparation, it is well to emphasize again that sulfanilamide should be used cautiously and, until more is known of its pharmacology, should not be administered concurrently with any other substance except sodium bicarbonate (see editorial in *THE JOURNAL*, October 2, p. 1128, and reports by the Council on Pharmacy and Chemistry in *THE JOURNAL* May 29, p. 1888, and July 31, p. 358).

5 Diethylene glycol, when taken in divided doses and in amount comparable to those recommended by the manufacturer for Elixir of Sulfanilamide-Massengill, is a decidedly toxic substance and cumulative poison; the pathologic picture was the same in animals that received a 75 per cent solution of diethylene glycol alone, a synthetic mixture made of 10 Gm of sulfanilamide in 100 cc of a 75 per cent solution of diethylene glycol, and the Elixir of Sulfanilamide-Massengill.

Special Article

MEDICAL PATENTS

MORRIS FISHBEIN, MD

Editor of the *The Journal of the American Medical Association*
and of *Hygeia, the Health Magazine*
CHICAGO

In the Principles of Medical Ethics of the American Medical Association it is stated quite plainly that:

It is unprofessional to receive remuneration from patents for surgical instruments or medicines, to accept rebates on prescriptions or surgical appliances, or perquisites from attendants who aid in the care of patients.

Through the centuries medicine has given freely of its discoveries for the benefit of mankind. Vaccination against smallpox, inoculation against hydrophobia, digitalis and innumerable other methods and medicaments became the property of all who cared to employ them in the control of disease. Now as medicine has become more complex, involving technical assistants in the fields of biochemistry, physiology, physics and associated branches, great numbers of people who give their full time to the work of the hospital, the laboratory or the care of the sick work with the medical profession but are not bound in any way by the same ethical principles.

Research workers in many universities have developed preparations and techniques in their laboratories at considerable expense to the institution. Workers in some instances have seen fit to turn over to the universities the control of such products. In other instances universities have refused to accept such responsibilities and the worker has taken some other method of administering the control of his discovery.

LACK OF UNIFORMITY

There appears to be no uniformity in the approach to this problem or in the decisions and rulings of various institutions on this subject. Insulin is controlled by the governors of the University of Toronto. Scarlet fever preparations are controlled by the Scarlet Fever Committee, Inc. Vitamin D preparations by irradiation are controlled by the Wisconsin Research Alumni Found-

dation of the University of Wisconsin, the Spertt patents for vitamin D by the University of Cincinnati, the Zucker patents for vitamin D by Columbia University, the Doisy patents for theelin by St. Louis University School of Medicine, and several others covering drugs by Stanford University and the University of California.

In 1934 a special committee of the American Association for the Advancement of Science recognized the desirability of obtaining patents for purposes of control. It pointed out that the act of securing patents for medical discoveries is not unethical in itself and that such act does not necessarily mean that personal profits are sought. It recognized the desirability for a patent in order to protect a manufacturer who wished to develop a product on a large scale. It recognized the tremendous expense which might be involved in developing an invention and the use of a patent to recoup the money spent in research. It recognized, finally, the right of a university with limited funds for research to use patents developed in its laboratories for encouraging further research.

Not only does the University of Toronto administer the insulin patent but in association with the university there is a pediatric research foundation which derives funds from discoveries that are used in the university for research.

The University of California administers the product called tethelin, developed by Robertson, formerly professor of chemistry and pharmacology. This patent is administered by a committee of five members of the faculty under the control of the regents of the university.

The board of trustees of the University of Pennsylvania in 1934 established the policy that any invention or discovery which may in any way affect the public health, such as a new drug, process or apparatus intended primarily for medical or surgical use, should not be patented for profit, either by the individual in the employ of the university or by the university itself. In order to prevent capitalization and exploitation by others, it is pointed out, the executive committee may from time to time consider it advisable to patent inventions or discoveries with the sole intent of protection without profit. In a later resolution it was stated that patents may, with the approval of the president of the university, be applied for, covering other inventions or discoveries, in which case the inventor shall assign his rights to the patent to the university on its paying the expense of securing the patent. Furthermore, it was left to the executive committee to determine what proportion of the profits, if any, should be given to the individual concerned, except that no profit was to be derived from patents or discoveries that may in any manner affect the public health.

Columbia University has set up an administrative board of medical patents with authority to accept or direct the development of discoveries made in its laboratories. This board is empowered to make arrangements for the use, manufacture, sale or other disposition of patents or discoveries. St. Louis University controls the Doisy patents on theelin and from the funds derived makes grants for research. The University of Illinois provides for the assignment of patents to the university and has set up committees for control, likewise Lehigh University. Harvard University has no specific rule about patents, except that no

member of the medical school or of the school of public health is permitted to take out a patent for his own profit or take any profit on a patent or on any invention or discovery that affects the health of individuals or of the public. If, however, to protect the public against misuse of the invention or discovery it becomes necessary to obtain a patent, it is possible to apply for it under such a name or conditions as the corporation or board of governors of the university may determine. The Johns Hopkins University in 1933 through the advisory board of the medical faculty went on record to the effect that it was undesirable for any member of the medical faculty to take out a patent on any discovery that might affect the public health. The University of Michigan provides also for the control of patents. Under the regulations of the Massachusetts Institute of Technology, any inventions resulting directly from research become the exclusive property of the institute, which, it is understood, the institute will administer for the benefit of the public. In case the institute decides not to acquire these rights, all or a part of them goes to the individual who made the invention.

The University of Minnesota has several patents and it has been held that it is not improper to use the control of patents as a means of adding to the research funds of the university. The thyroxine patent is one in the field of public health which this university controls. The University of Cincinnati has a large number of patents covering the preservation of food and in a recent decision has reserved to itself all medical discoveries to be administered for the public good. In 1932 Cornell University also arranged through a separate corporation to administer patents but has made no decision as to the distribution of royalties. The iodobismutol patent, now controlled by Stanford, is to be administered for the support of research in the medical school.

POINTS OF VIEW OF NATIONAL ORGANIZATIONS

In addition to the stipulations made by various universities, this problem has been considered by many national organizations in the field of science. The National Research Council permits the acquiring of patents arising from work which it has supported and the dedication of such patents to the public good. In fact, it announces the policy that those who make discoveries will apply for patents and that such patents will be assigned to the National Research Council.

The Carnegie Institution announced in 1923 its expectation that new and useful inventions or discoveries which resulted from research that it financed would be dedicated to the public use and that such patents would be assigned to the Carnegie Institution.

The Rockefeller Institute has recognized the necessity of patenting for purposes of control with the understanding that administration will be for the public good and that all such funds will be devoted to public purposes. Tryparsamide is one of the products on which the Rockefeller Institute holds a patent.

The Mellon Institute, which is largely supported by funds from commercial donors, controls patents with a contract whereby the discoveries are patented by the worker and the patent turned over to the donor, who makes the regulations as to control. This institute holds some 500 patents. Under the regulations of the Chemical Foundation, patents are assigned to the foundation which then administers them under a licensing system.

setting aside a portion for the disposal of the discovery and the remainder for research

This subject, which has attracted so much attention for so many years, has also been commented on by many of the leaders in the field of medical thought. In 1927 Dr Hans Zinsser pointed out that the relief of the sick and the prevention of unnecessary sorrow by the maintenance of individual and public health are not to be compared with the invention of improvement in the mechanism of automobiles or of a shoe buckle. Any procedure that prohibits the most rapid and useful application of a discovery to the needs of a community would seem to be as unjustified as cornering the wheat market.

METHODS BY WHICH MEDICAL INVENTIONS CAN BE PATENTED

In its survey of this subject the American Association for the Advancement of Science outlined the methods by which medical inventions can be patented in this country.

(a) Methods of medical treatment are in general difficult to patent, because the Patent Office is very reluctant in granting such patents. It appears that the courts have not definitely decided whether this type of invention is patentable. An old decision of the Patent Office held such patents to be contrary to public policy.

(b) Any remedial compound which is nothing more than such a mixture of medicinal agents as could be made by the exercise of the ordinary skill of a physician is not patentable. In the past, the Patent Office granted many patents for all sorts of remedial compounds, which were hardly more than physicians' prescriptions or at best were mixtures of known remedial compounds. Many of these patents were used as a means of exploiting the public with false claims and pretenses. The Patent Office today therefore refuses to grant patents for this type of remedial compound unless it can be shown that an entirely new and unforeseen result is obtained and that the ingredients coact to produce an entirely new result.

(c) New chemical compounds, organic and inorganic, having some remedial value can generally be patented. A large number of medicinals on the market are patented. The new compound is patentable as such and not necessarily as a medicine.

(d) Certain biological products and the processes for producing them may also be patentable. The Dick patent for scarlet fever toxin is a good example.

(e) Processes for manufacturing chemical compounds are patentable when they are novel and have not been previously used, known or described in the literature.

(f) The discovery of the medicinal or other properties of known compounds can in some instances be protected by a patent.

(g) Instruments, apparatus and so on, used in medical and surgical practice can also be patented.

Our patent laws are very liberal with regard to medicinal inventions as compared with those of European countries. In France, it is stated, pharmaceutical compositions or remedies of all kinds are excluded from protection. In Germany articles of food, medicines and substances manufactured by a chemical process are not patentable so far as the inventions do not relate to a distinct process of manufacturing such products. In England, it is said, foods and medicines are not patentable per se but the methods of manufacturing them may be patented. It should be pointed out that control of the process is just as effective as the patent of an article itself and that in many instances monopoly may be maintained by copyright of a well established name which is better than a monopoly dependent on the protection of a patent against infringement.

ATTITUDE OF AMERICAN MEDICAL ASSOCIATION

The attitude of the American Medical Association with regard to patents, aside from the inclusion of the clause already quoted in the Principles of Medical Ethics, was expressed by the House of Delegates in June 1914. The Judicial Council at that time recommended the adoption of the following resolution, which was thereupon duly adopted by the House of Delegates:

Resolved That the Board of Trustees of the American Medical Association shall be permitted to accept, at their discretion, patents for medical and surgical instruments and appliances and to keep these patents as trustees for the benefit of the profession and the public, provided, that neither the American Medical Association nor the patentee shall receive remuneration from these patents.

The Board of Trustees of the Association has not, however, as yet accepted any patents or endeavored to work out any plan for the administration and control of patents in the medical field. Since 1914, at various times, committees have been set up by the Board to study the problem and to report. No such final reports have, however, thus far been made available.

ADVANTAGES AND COMPLICATIONS IN TAKING OUT OF PATENTS

There are many arguments which may be made for and against the taking out of patents. When a patent is granted, those who control the patent regulate the production of the product so as to insure its quality. The owner of the patent may control the price to a considerable extent, thereby preventing exploitation. The owner of a patent may limit the production of the goods to organizations capable of making the best possible product and eliminate those capable of such production.

One of the chief complications in this field in recent years has developed from the fact that inventions or discoveries are far more frequently the result of the efforts of a number of workers than of any single discoverer and that in many instances only one of the group of workers may be a physician unauthorized to accept remuneration, whereas all of the others, because they are pharmacists, chemists, biochemists, physicists or physiologists, are not inhibited by such principles of ethics as control the medical profession.

In an earlier day, the doctor who developed a new device or appliance would manufacture a few with the aid of some neighboring blacksmith or carpenter. In modern times, industry is capable of turning out many thousands of units, in contrast to the ten or fifteen that might have been used formerly. Insulin was developed by biochemists, physiologists and a practicing physician. Certainly the name of Banting, the physician, is as much to be credited for the discovery of insulin as the names of his colleagues Macleod, Collip and Best. It is no secret that it became necessary to patent this discovery in order to control it, that Banting received one dollar for the sale of the patent to the University of Toronto, and that he derives not one cent of royalty from his discovery. The funds derived are largely spent on research under the control of the discoverers.

NEED FOR REVISION IN MEDICAL POINT OF VIEW

Our new order of living in the machine age, the development of specialization in medical practice, the incorporation of great industries for the exploitation of discoveries made in the laboratories and similar factors emphasize the need for some revision in the medical point of view concerning medical patents. The control

of such patents by universities has to some extent assured standardization of products. Usually only reputable firms capable of developing and exploiting products honestly are granted licenses to participate in the manufacture and sale of products controlled by the universities, although there are glaring exceptions.

While it is obvious that the entire trend of the times is toward the holding and control of patents, both medical and nonmedical, by educational and research institutions in order to provide suitable administration of the discoveries for the benefit of the public, it is obvious also that there are some arguments opposed to the holding of patents by universities. One of the most cogent arguments now advanced concerns the relationship of the university or research institute to taxation. Endowed universities and research institutions as well as scientific organizations and trust funds in the interest of the public are usually exempt from taxation. They are nonprofit organizations. They owe a definite duty to the public, which bears the burden of taxation. Universities must consider the extent to which exploitation of patents for the benefit of the institution may not bring on them the new burden of taxation from which they are now exempt. The exploitation of patents by universities places them in direct competition with one another. For example, there are now many patents concerned with the development of vitamin D. Because of the financial interests involved, the results of current research are jealously guarded and probably all research is being delayed through failure of research workers to communicate with one another. Indeed, it is known that workers in the same university, because of the rewards involved, may develop a competitive spirit which is likely to destroy entirely the type of cooperation in science which is responsible for much of our current progress. Such competition, in fact, defeats the whole purpose of a university. This point of view was beautifully expressed by Mr. G. W. Gray in his article on "Science and Profits" in *Harper's Magazine* for April 1936, when he said:

Scientific research, as a recognized full-time occupation, is one of the youngest of the professions. It has come up out of the basements and garrets of the early experimenters, and has attained status among the most honored of the callings of man. Perhaps the laboratory is pressed with economic necessity—but is that warrant for changing its charter? Possibly it can support itself handsomely and independently—but can it survive the shiftings of bases and the readjustments of outlook which commercialization entails? One of its greatest glories is its intellectual integrity and independence—but can this reputation continue unsullied in the clash of competitive sales campaigns of patented commodities, infringement suits, and other contentions of the marketplace in which the financial interest of the research institution is on one side of the dispute?

Patents are not administered by laws but by men. Contracts are not made by universities but by men. The difficulties which have arisen thus far in the control of patents in the medical field would seem to be difficulties which might easily have been avoided with the development of a proper spirit by those who administered the patents and by those who wished to use them. The difficulties are apparent in the various suits for infringement which have been filed from time to time in the courts and in the stipulations laid down by those who control the patents in relationship to research by others who might wish to carry the work still further.

The patents in the medical field which have aroused the most debate and trouble at present are the scarlet

fever patents held by the Scarlet Fever Foundation, the copper-iron patent held by the University of Wisconsin and perhaps also the various patents concerned with the production of vitamin D and vitamin D products. The sun in the sky should be freely available to all who wish to use it. Yet it has been hinted that there are some concerned with patents on vitamin D who would even inhibit investigators from experimenting with the sun.

The history of medicine reports innumerable instances in which curious minded doctors have combined all sorts of elements into preparations of various sorts in the administration and in the control of disease. No doubt each of the elements such as copper and iron has on occasion been combined with one or more of the others merely with a view to seeing what would happen and sometimes these, or worse combinations, have been put into the human body. Thus it is doubtful that the combination of any two well known elements may be considered a new procedure. Yet the question is raised as to whether or not the specific combination of two elements for a single apparently new purpose discovered by investigators in a laboratory does or does not constitute a discovery.

No doubt investigators long before the time of Drs. George F. and Gladys Henry Dick conceived the idea that the streptococcus was an important factor in scarlet fever and that products derived from the streptococcus might be used in the diagnosis, prevention and treatment of scarlet fever. Conceding that the Drs. Dick proved a certain streptococcus to be the cause of scarlet fever and developed thereby a method of diagnosis and means of determining susceptibility and methods for the prevention and treatment of scarlet fever based on their discovery, how far should they be entitled, under the patent granted them, to control research or other work with such products by other investigators? This has been a main bone of contention and quarrel for some years. Perhaps this difficulty may be credited to the fact that the administration and control of the patent lie with the discoverers themselves rather than with some wholly disinterested body capable of viewing the matter objectively.

When our civilization was such as to safeguard the physician, considering him as one who gave freely of his knowledge and service to mankind and therefore entitled to special considerations, physicians might well offer freely their time, their service and their original contributions to all mankind. Our complex civilization of today places ever new burdens on this willing bearer of mankind's tribulations. In many occasions and under many governments, physicians are now made employees of the state with some emolument and much control. Why should such a physician give freely to every one the product of his brain when the state refuses longer to recognize his professional status or to consider him as a philanthropic worker? It might be suggested that the state take over and control all patents in the field of health, but be reminded that the state has manifested no particular wisdom thus far in the granting of patents in the medical field. A patent was granted to Elisha Perkins for his electric tractors, to Sanche for that preposterous gas pipe called the Oxydonor. Patents have been issued covering flavoring of epsom salt, for a necklace supposed to cure goiter, for a tapeworm trap, for a method whereby the hen herself would date her eggs, for a shock-absorber bed and for a combination of chemicals alleged to confer firm immunity to most diseases, including syphilis, tuberculosis, diphtheria and other infectious diseases.

It would require a far finer organization of the patent office than now prevails to insure the public protection against fraud and exploitation with medical discoveries.

The act of securing a patent is not in itself unethical. Mere publication of a discovery does not protect the discoverer against exploitation of his patent by others. The administration of the patents covering insulin, liver extracts and many others has been shown to be for the public good. Manufacture has been standardized. Products of quality are provided for the public and, because of the protection, the prices of such products have been steadily reduced from the time when they were first offered to the people. It is doubtful that a high quality standardized product at a minimum price could have been made available nearly so soon had these preparations been thrown into the open market. Moreover, there is no question but that inferior products in vast numbers would also have been offered for general use. Finally, under our patent system, unless the discoverer or the university controls the patent, some one not bound by any ethical considerations whatever may patent the product and the process and thus take it away from those responsible for its discovery and development. The committee of the American Association for the Advancement of Science has suggested the desirability of patents in the medical field in order to encourage manufacturers in the development of high quality products at low prices, to recoup investigators for funds spent in research, and for the devotion of excess funds to further research.

CONCLUSION

In 1933 I concluded an editorial on the subject of medical patents with the following paragraph: "Conceivably the best interest would be served if some central body might be developed, wholly altruistic in character, capable of administering medical patents for the benefit of the public, and assuring a reasonable remuneration to the investigator, the devotion of much of the profit to research, and adequate return to manufacturers willing to develop quantity production and distribution in an ethical manner. Such a central body might also set up requirements for adequate clinical research in connection with the development of new products so that a premature launching of unestablished products on the medical profession or on the public could be avoided."

With that suggestion I still concur. It has seemed to me that the American Medical Association with its prestige, its central organization and its available funds might well stimulate the development of a corporation, not for profit, for the administration of patents in the medical and health fields. To this corporation inventors might assign the patents taken out by them with the understanding that the corporation would administer the patents within the limitations suggested and that the expenses of administration with suitable royalties to investigators, universities, research institutions or other bodies might be derived from the income available through licensing of well established firms to manufacture products under the patents.

The confusion of plans in the various universities, the vicious and sometimes malicious criticism of discoverers and of universities, the legal difficulties in which the universities sometimes find themselves and the basic principle enunciated in the Principles of Medical Ethics all seem to point toward the necessity of some unbiased body to assume responsibility and control in this field.

535 North Dearborn Street

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

SUPRARENALIN (See New and Nonofficial Remedies, 1937, p. 223)

The following additional dosage form has been accepted:

Suprenalin Solution 1:100 (For Oral Inhalation) Suprenalin, 1 part in 100 parts of physiologic solution of sodium chloride containing 0.5 per cent chlorbutanol and not more than 0.1 per cent sodium bisulfide.

CEVITAMIC ACID (See New and Nonofficial Remedies, 1937, p. 456)

Cevitamic Acid-Lederle—A brand of cevitamic acid—N N R, obtained from the fermentation of certain sugars.

Manufactured by Lederle Laboratories Inc., Pearl River, N. Y. No U. S. patent or trademark.

Tablets Cevitamic Acid Lederle 0.01 Gm.

Tablets Cevitamic Acid Lederle 0.05 Gm.

POLLEN ANTIGENS—"National" (See New and Nonofficial Remedies, 1937, p. 39)

The following preparation is marketed in 5 and 15 cc. vial packages representing 25, 50, 100 and 250 units per cubic centimeter.

Mixed Grass Pollen Antigen National (Timothy 75 per cent, June Grass, Orchard Grass, Red Top, Rye and Sweet Vernal Grass each 5 per cent)

Manufactured by the National Drug Co., Philadelphia. No U. S. patent or trademark.

BISMUTH SUBSALICYLATE (See New and Nonofficial Remedies, 1937, p. 133)

Bismuth Subsalsylate in Oil 2 grains per cc. A suspension containing 2 grains of Merck's bismuth subsalicylate in 1 cc. oil of sesame.

Prepared by the National Biological Distributors Inc., Baltimore. No U. S. patent or trademark.

IPRAL SODIUM (See New and Nonofficial Remedies, 1937, p. 106)

The following dosage form has been accepted:

Elixir Ipral Sodium Contains ipral sodium 13.17 Gm. in 1,000 cc. in a menstruum composed of alcohol 22 per cent, glycerin, saccharin and water, flavored with a mixture of pineapple concentrate, orange syrup, fluidextract of kola, fluidextract of casarea and tincture of cardamom compound. One teaspoonful (5 cc.) is equivalent to 1 grain of ipral sodium.

PROCAINE-ABBOTT See New and Nonofficial Remedies, 1937, p. 69)

The following dosage form has been accepted:

Ampoules Procaine Hydrochloride Solution 2% 100 cc. Each cubic centimeter contains procaine hydrochloride 0.02 Gm., sodium chloride 0.0044 Gm., sodium bisulfite 0.001 Gm. and distilled water to make 1 cc.

SULFANILAMIDE (See THE JOURNAL, July 31, 1937, p. 358, Supplement to New and Nonofficial Remedies, 1937, p. 17)

Sulfanilamide-Gane & Ingram—A brand of sulfanilamide—N N R.

Manufactured by Gane Chemical Works Inc. (Gane & Ingram Inc. distributors). No U. S. patent or trademark.

Sulfanilamide-Monsanto—A brand of sulfanilamide—N N R.

Manufactured by Monsanto Chemical Co., St. Louis. No U. S. patent or trademark.

Sulfanilamide—"National"—A brand of sulfanilamide—N N R.

Manufactured by the National Drug Co., Philadelphia. No U. S. patent or trademark.

Sulfanilamide Tablets 5 grains

Sulfanilamide-P. D. & Co.—A brand of sulfanilamide—N N R.

Manufactured by Parke, Davis & Co., Detroit. No U. S. patent or trademark.

Sulfanilamide Tablets 5 grains

DEATHS FOLLOWING ELIXIR OF SULF- ANILAMIDE-MASSENGILL III

Thirty-five years ago William Osler wrote

To modern pharmacy we owe much and to pharmaceutical methods we shall owe much more in the future, but the [medical] profession has no more insidious foe than the large borderland pharmaceutical houses. No longer an honored messmate, pharmacy in this form threatens to become a huge parasite, eating the vitals of the body medical. We all know only too well the bastard literature which floods the mail, every page of which illustrates the truth of the axiom. The greater the ignorance the greater the dogmatism. Much of it is advertisements of nostrums foisted on the profession by men who trade on the innocent credulity of the regular physician, quite as much as any quack preys on the gullible public. Even the most respectable houses are not free from this sin of arrogance and of ignorant dogmatism in their literature. A still more dangerous enemy to the mental virility of the general practitioner is the "drummer" of the drug house.¹

During the intervening years the work of the Council on Pharmacy and Chemistry has brought about vast improvement among leaders in the pharmaceutical field. Unfortunately many smaller and unenlightened groups of pharmacists and pharmaceutical manufacturers fail to recognize the importance of high standards in all the professions concerned with health. It is still possible for such manufacturers to place on the market semisecret preparations, untested as to either toxicity, potency or therapeutic value.

Sixty deaths are known to have resulted from the administration of the Elixir of Sulfanilamide distributed by Massengill. Under our present laws the responsibility for protection of the public rests on the Food and Drug Administration, which is as inefficiently armed as a hunter pursuing a tiger with a fly swatter. Under our present laws there is nothing to require the S. E. Massengill Company or any other firm to divulge the formula or to make adequate pharmacologic or clinical tests before placing a hazardous "patent medicine" or proprietary preparation on the

market. Ironically the label for Elixir of Sulfanilamide-Massengill carried the recommendation "continue at this dose until recovery."² In reply to a question by a physician who had lost a patient after having prescribed the mixture, a letter bearing the signature S. E. Massengill was sent.

"We have your letter of the 22nd instant and regret very deeply the fatal result that you had when administering the above product. We are sorry that we cannot give you any information as to why this should have happened. Many chemists are now working on the problem and so far no solution of a scientific nature has been made.

"We regret exceedingly this unfortunate occurrence but as we violated no law and made no error in our manufacture I do not think that we should be blamed by the unlooked for action of this product."

Thus speaks a firm which has done essentially nothing to contribute to the knowledge of medicine and which would capitalize on the discoveries of others, by exploiting a semisecret preparation! Who should have made certain of the safety of the preparation if not the purveyor? In the cycle comes first the manufacturer who launched the preparation without proper precaution, second, the detail man who importuned physicians to use the product, third, the pharmacist who was willing to sell across the counter, either on request from the public or on physicians' prescriptions, toxic preparations of secret character, yet whose training is vaunted as a protection to the public. But most serious perhaps after the manufacturer are those physicians who will not heed the warnings concerning the use of proprietary, unstandardized, semisecret remedies. This phase has been adequately discussed editorially in the two previous issues of THE JOURNAL.

Perhaps the physicians who used this product were misled by the term "Elixir." In general that term has connoted sweetened, aromatic, hydro-alcoholic liquids similar to cordials, to which active drugs are added. This definition, however, has undergone some changes in the practice of pharmacy by the employment of other solvents, such as glycerin. There is no legal definition of the term "Elixir." The U. S. Pharmacopoeial Revision Committee or some group with legal power should define "Elixir" and similar terms.

As has been cautioned repeatedly, sulfanilamide should not be used with other drugs except sodium bicarbonate. It decomposes in ordinary vehicles. In the case of the diethylene glycol vehicle devised by Massengill, the product did not decompose but the patients did die.

Elsewhere² in this issue of THE JOURNAL is an extended report on the chemical composition of the product, on the pharmacologic work following the administration of Elixir of Sulfanilamide-Massengill to animals, and on the studies of necropsy material from

¹ Excerpt from lecture Chauvinism in Medicine given before the Canadian Medical Association, Montreal, 1902 and from the book *Aquaintances and Other Addresses* by William Osler, Philadelphia: P. Blakiston's Son & Co. 1906, p. 300.

² This issue, p. 1531.
³ The reports of Dr. Geiling and Dr. Cannon are reprinted and optimized. Details and reports of observations on the action of sulfanilamide may be the subject of future contributions to the literature.

both animals and man. These studies have been under way day and night since the middle of October. The chemical analysis shows that the product contained approximately 72 per cent of diethylene glycol by volume. The pharmacologic investigations show that there is no essential difference in the results whether Elvir of Sulfanilamide-Massengill in the doses recommended or comparable doses of a "synthetic" mixture of diethylene glycol are administered. The pathologic examinations reveal that the picture of death is similar in human and animal necropsy material. The terminal symptom in all the instances recorded was anuria.

Sixty persons have been sacrificed simply because the toxicologic observations now reported were not determined in advance by a manufacturer who had no hesitancy in importuning physicians to use the elvir. Both chemical and medical literature contain references to the toxicity of diethylene glycol in the amounts recommended by the manufacturer. Diethylene glycol, administered in doses comparable to the dose recommended by the manufacturer of Elvir of Sulfanilamide-Massengill, acts as a cumulative poison. Surely there has been no blacker picture of the inadequacy of our present food and drug laws or the lack of common scientific decency in drug manufacture than that illustrated by this tragic disaster.

ANTIDIURETIC HORMONE OF THE POSTERIOR PITUITARY

In 1895 Oliver and Schafer first demonstrated the action of posterior pituitary extracts on the vascular system. Since then preparations have been made which are suitable for clinical use, but the hormone or hormones of the posterior pituitary have not been isolated in chemically pure form. Some of the problems of the posterior pituitary must await the identification in chemically pure form of the "mother" substance of Abel,¹ its fractional derivatives or separate fractions.² The physiologic investigations of this gland have already far outstripped chemical studies. It seems likely, therefore, that chemical purification will merely settle the controversy that has existed as to whether a single hormone is responsible for the diverse physiologic actions of the posterior pituitary or whether at least three or more active principles exist as such and are transported as separate entities in the blood stream.

Not the least striking of the properties of posterior lobe extracts is their antidiuretic activity. The site of this action has been the subject of considerable experimentation and debate. It is generally accepted that in man, at least, the effect of therapeutic doses of pituitary extract is due to an increased water reabsorption

in the renal tubule. The kidney appears, therefore, to be under the hormonal control of the pituitary gland with respect to reabsorption of fluid from tubular activity. However, conclusive evidence for the true hormonal nature of the antidiuretic principle has been lacking. When account is taken of the exactness with which the degree of body hydration is maintained, it seems likely that the relationship between the gland and the kidney must be a readily adjustable one and therefore probably under hormonal control. This assumption presupposes that the body requirements for water absorption in the kidney will to a large measure determine the degree of hypophyseal activity in the production of the antidiuretic hormone. Convincing proof of this postulate has been recently presented by Gilman and Goodman,³ working in the laboratories of the Yale University School of Medicine.

The relative stability of pituitary extracts in urine suggested to these investigators that the antidiuretic hormone might be demonstrated in this body fluid whenever it was necessary for the organism to conserve water. Under such conditions the blood concentration of the hormone might rise to levels exceeding the renal threshold, thus permitting the substance to pass into the urine. They produced this physiologic need for the conservation of water in rats that were dehydrated by either water and food withdrawal or by oral administration of sodium chloride. Suitably concentrated and dialyzed urines from these animals showed, on bio-assay, marked antidiuretic activity. Control animals, given water ad libitum, showed no urinary excretion of the antidiuretic hormone. Experiments were also conducted on hypophysectomized animals. This group of animals, from seven to fourteen days after operation, was deprived of all water during the period of urine collection and normal control animals were dehydrated at the same time under identical experimental conditions. The volume of urine from the hypophysectomized group of rats was approximately three times greater than that from the controls. It is evident, therefore, that the experimental animals were more dehydrated than the control group and had a greater stimulus for water conservation. Despite this need, however, assay demonstrated that the urine of the hypophysectomized rats contained no antidiuretic substance, while the control urine exhibited unmistakable antidiuretic activity. Thus it would appear that the pituitary gland is definitely the source of the antidiuretic substance in the urine. Further proof of the hypophyseal origin of the antidiuretic principle of the urine was obtained by the demonstration of a similarity between the chemical properties of pharmacologic preparations from the gland and the urinary principle. The results offer definite evidence for the hormonal role of the antidiuretic principle.

FOOD AND DRUGS LEGISLATION

The unnecessary deaths of more than sixty people who took a pharmaceutical preparation labeled "elixir of sulfanilamide," secret in composition and unstandardized, emphasizes again the importance of securing as soon as possible adequate legislation relating to foods, drugs, diagnostic and therapeutic devices and cosmetics. Either by amendment of present food and drugs laws or by the passage of new laws the public must be protected. The Food and Drugs Act of 1906, as pointed out in the special article on this subject by our Bureau of Legal Medicine and Legislation, published elsewhere in this issue, fails in various ways to protect the consumer. It does not provide adequate standards of purity, potency, wholesomeness and labeling of foods and drugs, nor does it provide for suitable penalties when foods and drugs fail to meet such standards as it does establish. It provides no standards for diagnostic and therapeutic devices or for cosmetics. Moreover, the many loopholes in this legislation make evasion easy for those who wish to evade. Finally, that legislation was passed at a time when modern advertising was in its infancy, it provides no potent weapon against false or fraudulent advertising of foods, drugs, devices or cosmetics.

The proposed legislation, introduced into Congress beginning with the Tugwell-Copeland bill of the Seventy-Third Congress and passing through various phases in the Seventy-Fourth and the Seventy-Fifth Congress, is not adequate. From a legal point of view it seems weak in many particulars. One of the greatest weaknesses is the failure to set up adequate legal standards for drugs and diagnostic and therapeutic devices or to establish machinery by which such standards can be established. Had there been such standards, with adequate penalties for violation, the elixir of sulfanilamide tragedies would probably never have occurred. Indeed, as was emphasized in our editorial last week, present legislation is so inefficient that the Food and Drug Administration had to act by a special technical interpretation of the present law.

The Wheeler-Lea bill proposes to vest in the Federal Trade Commission supervision and control over the advertising of foods, drugs, diagnostic and therapeutic devices and cosmetics, leaving to the Food and Drug Administration supervision and control over their adulteration and misbranding. Under such an arrangement there will be not only duplication of effort but also conflict of interest from which the chief sufferer will unquestionably be the public, which is in need of protection. Division of authority and responsibility for the enforcement of food, drug and cosmetic legislation is dangerous. If the Wheeler-Lea bill is to be passed, certainly it should be amended to prevent such division of responsibility between the Federal Trade Commission and the Food and Drug Administration of the Department of Agriculture as would inevitably arise under the bill as now written.

The Copeland bill now pending before the Committee on Interstate and Foreign Commerce of the House of Representatives is a much better planned bill as far as effective protection of the consumer is concerned. The advertising provision and those relating to standardization in the Copeland bill may well be strengthened. If it is impossible to pass the Copeland bill, and if the desires of the Administration and of the Congress are for passage of the Wheeler-Lea bill, Congress should well consider the advisability of placing all the responsibility on the Federal Trade Commission rather than dividing it. In such action, however, it should bear in mind that the Food and Drug Administration has had many years of actual experience in enforcing food and drugs legislation. Most important, however, is adequate provision for establishment of obligatory legal standards for drugs and other materials used in the human body. Until such standards are created and until the penalties for violation are made sufficiently severe, there will be possible disasters such as the deaths from elixir of sulfanilamide, which for more than a fortnight have continued to shock the nation.

Current Comment

CANADA CLEANS UP THE RADIO

The Canadian Broadcasting Corporation has promulgated regulations, effective November 1, designed to improve the standard of broadcasting. Among them are some regulations that should react to the betterment of the public health. Hereafter an article marketed under the Proprietary or Patent Medicine Act or the Food and Drugs Act may not be broadcast until it has been approved by the Department of National Health. The formula for any article bearing a distinctive or trade name distinguishing it from any other product, and marketed under the Food and Drugs Act, shall be submitted with each pertinent continuity at least two weeks in advance of the time at which the continuity is to be broadcast. No continuity recommending any treatment for any ailment shall be broadcast until it has been approved by the Department of National Health. No station shall "pick up" and rebroadcast any program unless permission in writing has first been obtained from the Canadian Broadcasting Corporation. Hereafter, no one shall broadcast advertising matter that contains false or deceptive statements. No one shall broadcast on the subject of birth control or on the subject of venereal disease or other subjects relating to public health unless such subjects are presented in a manner and at a time approved by the general manager as appropriate to the medium of broadcasting. No one shall broadcast programs presenting a person who claims supernatural or psychic powers, or fortune teller, character analyst, crystal gazer or the like. No program shall be broadcast in which a person purports to answer or solve problems submitted by the public unless such programs first shall have been approved.

writing by a representative of the Canadian Broadcasting Corporation. No one shall broadcast over the Canadian radio facilities the actual proceedings of any trial in a Canadian court or any abusive comment on any race, religion or creed. No one shall broadcast any advertising matter containing false or deceptive statements, and the advertising content of any program shall not exceed 10 per cent of the time of any program period. No one shall advertise spirituous liquors in any broadcast program. So-called spot announcements shall be limited to two minutes for each broadcasting hour and shall not be broadcast between 7 30 p m and 11 p m nor on Sundays at any time. No broadcasting station in Canada shall continue to be a part of a chain or network originating outside of Canada unless permission in writing is first obtained from the Canadian Broadcasting Corporation, also unless such permission is granted, no chain or network of two or more stations shall continue to be operated within Canada, and no station shall continue to be an outlet for any station, chain or network outside of Canada. There are many other new Canadian broadcasting regulations which, however, do not so directly affect the public health. Thus we shall receive from our northern neighbor radio broadcasts of purity in contradistinction to the quackery, fortune teller and "patent medicine" promotion that comes floating like a foul effluvium across the Rio Grande. The new Canadian broadcasting regulations may also serve as a suggestion much needed by our own broadcasting chains.

PASSIVE IMMUNITY IN MALARIA

Although it has been generally accepted that some immunity exists on recovery from malarial infections, reports in the literature on the protective property of serum taken from patients or animals with chronic malaria have been conflicting. Recently, however, Coggeshall and Kumm¹ reported a series of experiments on monkeys, employing two different types of parasites, which appear to demonstrate this phenomenon conclusively. The two strains used were *Plasmodium knowlesi* and *Plasmodium inui*. Macacus rhesus monkeys were used exclusively in the experiments and were infected by intravenous injection of citrated blood containing a known number of parasites.

Thirty-two animals were used in the observations in eight groups of experiments devised to test various aspects of passive immunity. The results seem to indicate that while the immune serum obtained from monkeys with chronic malarial infections definitely afforded good protection in some animals into which it was injected, it completely failed in others. These authors offer no adequate explanation for this circumstance but suggest that in addition to individual variation in the susceptibility of the monkeys there may be considerable variability in the concentration of the immune substances of the serum of the individual monkeys harboring a chronic infection from which the pooled serum was obtained. They concluded that when

Plasmodium knowlesi infection, which is almost invariably fatal in rhesus monkeys, can be made chronic by the early administration of antimalarial drugs, the animals then will harbor chronic infection for an indefinite period. The serum from such monkeys when injected into others with an acute attack has been found to have a definite inhibiting effect on the course of the experimental disease. These data indicate that protective antibodies are produced in the serum of monkeys during experimental malarial infection and can be demonstrated by animal protection experiments. The clinical applications, if any, however, cannot be ascertained as yet.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARIZONA

Hospital News—A new \$48,000 hospital has been opened in Yuma County, with facilities for seventy-nine patients.

Society News—Dr Leslie M. Smith, El Paso, Texas, addressed the Cochise County Medical Society, Bisbee, recently on "Fungus Infections of the Southwest."

COLORADO

Personal—A portrait of the late Dr Samuel D. Gross, Philadelphia, was recently presented to the library of the Medical Society of the City and County of Denver by Dr William M. Bane. The portrait is done in charcoal and is the work of Dr Bane's father, the late Dr William C. Bane, for many years a member of the faculty of the Denver and Gross Medical College.

DELAWARE

State Medical Election—Dr Clarence J. Prickett, Smyrna, was chosen president elect of the Medical Society of Delaware at the recent annual meeting. Dr Charles P. White, Wilmington, is president for the coming year. Dr Allan V. Gilliland, Smyrna, has been elected secretary, succeeding Dr William H. Speer, Wilmington. The new officers will take office January 1. The next annual meeting will be held in Dover, Oct 10-12, 1938.

Society News—Dr Thomas Grier Miller, Philadelphia, addressed the New Castle County Medical Society, October 19, in Wilmington, on "Indigestion." Dr Hugh H. Young, Baltimore, addressed the society, September 21, on "Diseases of the Prostate Gland."—Dr Lewis Kracer Ferguson, Philadelphia, discussed "Practical Points in Treatment of Surgical Lesions in Ambulatory Patients," November 1, before the Delaware Academy of Medicine, Wilmington.

FLORIDA

Personal—Dr William M. Weems, formerly of Clopton, Ala., has been appointed health officer of Palm Beach County.—Dr Alvin L. Stebbins, Punta Gorda, has been appointed health officer of Manatee County.

First Annual District Meeting—The first annual meeting of the Southwest Medical District of the Florida Medical Association will be held at the City Hall, Plant City, November 11. Dr George L. Cook, Tampa, president, Hillsborough County Medical Society, will deliver the address of welcome. Other speakers will be:

Dr Douglas D. Martin, Tampa, Appendicitis in Children.
Dr Shaler A. Richardson, Jacksonville, Quinine Amblyopia.
Dr Herman W. Waton, Lakeland, Disturbances of the Thyroid Function.

GEORGIA

Personal—Dr Thomas W. Collier, formerly of Albany, Ala., has been appointed health commissioner of a joint health unit for Toombs and Montgomery counties; his headquarters will be in Lyons.

¹ Coggeshall, L. T. and Kumm, H. W. Demonstration of Passive Immunity in Experimental Monkey Malaria. *J. Exper. Med.* 66: 177 (Aug.) 1937.

IDAHO

Personal—Dr James O Cromwell, Gooding, has been appointed in charge of the state mental hospital at Blackfoot. Dr Luther C Thompson, formerly with the Civilian Conservation Corps, will succeed Dr Cromwell in Gooding, according to *Northwest Medicine*.

ILLINOIS

Survey of Medical Services of Prisons—The report on a survey of medical services in the penal institutions of Illinois made by a special committee under the auspices of the Institute of Medicine of Chicago has been published. The report is concerned primarily with determining requirements for a modern medical program as adapted to the institutions studied. The medical services of the federal penitentiary system were used as a basis of comparison. Since 1930, when the federal system for this care was reorganized, these services have been under the supervision of the U S Public Health Service. Prior to the reorganization, the medical services, including the setting of standards, were left to the local administration of each prison. In its study the committee compared the medical personnel and the quantity of medical service rendered to the male inmates of federal prisons and those in the Illinois state prisons. For comparable average populations of about 10,000 in each case, the federal system has a total of forty-nine physicians, including twenty-four resident full time and twenty-five nonresident, part time, in attendance. Illinois has five resident full time physicians, including three psychiatrists, and eight nonresident part time physicians, a total of thirteen, exclusive of the services of two interns during the summer. The federal system reports 174,812 days of hospital care and 421,128 visits of ambulatory patients to the medical services, while Illinois reports 54,004 days of hospital care and 143,994 visits of ambulatory patients. The report states that these figures "reflect the difference between the services the institutions are called upon to perform when the initiative is left largely to the individual prisoner, as is the case in Illinois, and when the medical service itself takes the initiative in finding and following up conditions which may be benefited by treatment, as is the case in the federal system." The study reveals that the states' medical services are being carried on as they were in the federal institutions previous to 1930 and concludes "that the medical services display a type of organization, or lack of organization, suitable to a generation or more ago, when these services were presumably instituted. While they function as well as may be expected under these conditions, they fall far short of the requirements for the modern, aggressive health service now regarded as essential for large populations under similar conditions."

Chief among the committee's recommendations is the reorganization of the general medical and surgical services on a state-wide basis, under the supervision of a physician to be attached to the department of public welfare, with responsibility for the setting of standards and for the selection of medical personnel. The committee also recommends installation of a graded personnel, making the service attractive as a medical career and a considerable increase in the total medical personnel. Specific recommendations are made for the control and treatment of tuberculosis and venereal disease, and a plan is proposed for improving the quality of major surgery. The committee points out that Illinois has been a pioneer in the organization of a modern psychiatric service and recommends no change in this service, although it urges an increase in personnel. It estimates that all of its recommendations can be carried out at an added cost of not to exceed three cents a day for each individual in the prison population. The salary schedule for 1936 for the general medical and surgical services totaled \$17,880, while the proposed increase in a reorganized service calls for an additional \$44,000. The committee estimates that the ultimate cost of a complete and comprehensive reorganization should not exceed \$100,000 annually. The institutions studied were those at Joliet, Menard, Pontiac, Vandalia and Dwight. Members of the committee, which was appointed Nov. 13, 1935, comprised Drs Franz G Alexander, Clarence F G Brown, Walter M Brunet, Francis J Gerty, Jerome R Head, Don C Sutton, Franklin C McLean, Chicago, chairman, and Frank L Rector, Evanston.

Chicago

Changes in the Faculty at Loyola—Recent changes on the faculty at Loyola University School of Medicine include the appointment of Dr William R Cubbins as professor and director of a new division of bone and joint surgery, Julius Sendrov Jr, Ph.D., as professor and head of a new department of experimental medicine and the appointment of

Dr Henry Schmutz, head of the department of gynecology, as head of the department of obstetrics to succeed Dr Bertha Van Hoosen, who becomes professor emerita. Other changes include

Dr Thomas F Finegan, professor of urology;
Dr Robert E Cummings, assistant clinical professor in pediatrics;
Dr H William Elghammer, clinical professor of pediatrics;
Dr William J Pickett, associate clinical professor of surgery.

Society News—The Chicago Gynecological Society was addressed, October 22, by Drs Franklin E Hall on "Inversion Uteri" and James E Fitzgerald on "Hyperemesis Gravidarum."—The Chicago Ophthalmological Society was addressed October 25, by Drs William F Moncreiff on "Contact Lenses: A New Technique for Making Impressions of the Anterior Segment," James W White, New York, "The Occurrence of Divergence Excess Associated with Vertical Anomalies," and Theodore L Terry, Boston, "Concerning the Pathology of Glaucoma."—At a meeting of the Chicago branch of the American Chemical Society, September 24, Dr Leon Unger and Marjorie Moore, Ph.D., discussed "Cooperative Studies on Hay Fever and Other Allergic Conditions."—The Chicago Society of Internal Medicine will be addressed November 22, among others, by Dr Harold C Lueth and Thurt G Hanks on "Some Unusual Reactions to Nitroglycerin in Patients with Hypertension."—Dr Walter E Dandy, adjunct professor of neurologic surgery, Johns Hopkins University School of Medicine, Baltimore, addressed the Englewood branch of the Chicago Medical Society, November 2, on "Diagnosis and Treatment of Lesions of the Cerebral Nerves." The Irving Park branch was addressed November 2 by Drs Archibald L Hoyne on "The Later Stages of Poliomyelitis: Treatment and Prognosis," and Fremont A Chandler, "Orthopedic Management." Poliomyelitis was also discussed at the meeting of the South Chicago branch October 26, the speakers were Drs Sidney O Levinson and H William Elghammer.

IOWA

Another County Health Unit Organized—The Polk County Health Unit was organized August 18. The new unit will not function in or serve the city of Des Moines but the personnel of the unit will cooperate with the city's health commissioner, Dr Harry E Ransom, in borderline public health conditions affecting both city and county. The state will maintain the department. Dr Thomas E Eyres is health officer of the new unit with headquarters in the City Hall at Des Moines.

Health Lectures for High School Students—The second annual course in public health for all high school students in Crawford County, under the auspices of the Crawford County Medical Society, began September 20. Lectures arranged by the association will be given periodically in nine schools during the school year. The course is planned as an annual project so that after the first four years graduating students will have had thirty-six hours of public health lectures. The program this year is as follows:

Dr Ralph E Haskell, Denison, Infection Resulting from Injuries;
Dr Simon A Huber, Charter Oak, Diseases and Care of the Ear, Nose and Throat;
Dr Eugene J Maitre, Vail, Venereal Diseases;
Dr Edward M Mark, Manilla, Diseases and Care of the Skin;
Dr Frank N Rowe, Denison, Diseases, Defects and Care of the Eyes;
Dr Claudius L Stevens, Denison, The Care of the Heart;
Dr Thomas L Vineyard, Dow City, Tuberculosis in High School Age;
Dr Dora E Kielhorn, Zarske, Charter Oak, Infectious Diseases of the Respiratory Tract Other Than Tuberculosis;
Dr John James Duffy, Denison, Epidemic Infections of the Central Nervous System (Infantile Paralysis and Spinal Meningitis).

KANSAS

Society News—Dr Lester R Dragstedt, Chicago, discussed "The Etiology of Gastric and Duodenal Ulcer" before the Kansas City Academy of Medicine, October 15.—Dr Karl A Menninger and Norman Reider, Topeka, addressed a joint meeting of the Marion, McPherson and Harvey county medical societies at Marion, October 27; their subjects were "The Psychoneurotic and the General Practitioner" and "Headaches," respectively.—Dr Ernest E Tippin, Wichita, addressed the Marion County Medical Society, September 29, on "Physiology of the Nose."

KENTUCKY

Personal—Dr Henry G Wells, Richmond, has resigned as health officer of Madison County.—Dr William A Krieger, Newport, has been appointed city health officer to succeed Dr John Todd.

Society News—A symposium on traumatic surgery was presented before the Jefferson County Medical Society at Louisville, October 18, by Drs Ira N Kerns, Robert O Jones,

James Allen Kirk and Herman Mahaffey. Dr Joshua B Lukins also made an address on malpractice—Drs William Austin Bloch and Max L Garon, Louisville, addressed the Grant County Medical Society, Williamstown, September 22, on "Deficiencies of the Thyroid." Dr R Hayes Davis, Louisville, spoke at a recent meeting on "Functional Diseases"—Dr Lucius E Smith, Louisville, addressed the Letcher County Medical Society, Jenkins, September 21, on tuberculosis

LOUISIANA

Personal—Dr James W Tedder has been appointed assistant professor of dermatology at the Louisiana University Medical Center—Dr Herbert N Barnett, New Orleans, has been appointed acting health director of Bossier Parish, succeeding Dr Murphy M Sims, Benton, who resigned to enter private practice in Waskom, Texas

Society News—At the meeting of the Orleans Parish Medical Society, October 11, the speakers included Drs William H Perkins, professor of preventive medicine Tulane University of Louisiana School of Medicine, New Orleans, on "Relation of Preventive Medicine to the Federal and State Welfare Program," and Elizabeth Wisner, Ph D, dean, school of social work at Tulane, "Some Phases of the Social Security Act"—At a meeting of the Tri-Parish Medical Society in Lake Providence, September 7, Drs John H Burge, Lake Village, Ark, discussed "Infections of the Hands and Feet," and Smith W Douglas, Eudora, Ark, "Medical Fads and Fallacies"

MARYLAND

Fund for Educational Purposes—A foundation endowed with \$500,000 will be created for charitable, educational or research purposes, under the will of the late Louis Blaustein, Baltimore. It will be known as the Louis and Henrietta Blaustein Foundation. The income from the fund may be used or its principal, it may go for medical or sociological research, education, recreation or any other benevolent purpose, it may be spent in Baltimore or elsewhere

MASSACHUSETTS

Society News—Dr Soma Weiss, associate professor of medicine, Harvard University Medical School, Boston, addressed the opening meeting of the South End Medical Club, October 19, on "Syncope, Collapse and Shock."—At a meeting of the Norfolk District Medical Society in Boston, October 26, Dr William Dameshek, Boston, discussed "Leukemia and Related Disorders."—Dr George S Sprague White Plains, N Y, discussed "The Rationale of Psychiatric Therapy" before the New England Society of Psychiatry in Westborough, October 19.—At a meeting of the New England Heart Association and the Suffolk District Medical Society, October 25, Dr Milton C Winternitz, New Haven, Conn, spoke on "Pathology of Vascular Diseases."—The Boston Society of Psychiatry and Neurology was addressed, October 21, by Drs Leon J Robinson, Palmer, on "Syncope, Convulsions and the Unconscious State Their Relationship to the Hyperactive Carotid Sinus Reflex Among 1,000 Patients in an Institution for Epilepsy," and Calvert Stein, "Practical Aspects of Child Guidance—A Critical Analysis of 500 Cases from the Springfield Hospital Child Guidance Clinic."—At a meeting of the Harvard Medical Society in the Peter Bent Brigham Hospital, Boston, October 26, Drs William G Lennox and Frederic A Gibbs discussed "Epilepsy in the Light of Recent Brain Wave Studies"

Control of Hazardous Dusts and Fumes—The following committee has been appointed to assist the state department of labor and industries in the preparation of rules and regulations for the control of hazardous dusts and fumes in the manufacturing establishments of the state

Dr Joseph C Aub of the Collis P Huntington Memorial Hospital
E H Ballard general foundry superintendent General Electric Company
John Daniels legislative agent Associated Industries of Massachusetts
Philip Drinker CE professor of industrial hygiene Harvard School of Public Health
Laurence Foley international president Granite Cutters International Association of America
Dr Francis T Hunter of the Massachusetts General Hospital
William M Kand president Merrimac Chemical Company
Robert J Witt secretary treasurer Massachusetts Federation of Labor
Stephen E Whiting chief engineer Liberty Mutual Insurance Company

According to Manfred Bowditch, director division of occupational hygiene the committee is studying the establishment of maximum allowable concentrations of industrial fumes. As

a basis for the determinations it is using a tabulation in which all standards known thus far to have been promulgated are combined with tentative figures proposed by the division of occupational hygiene and in addition it has obtained the criticisms of twenty-two authorities in this country and abroad to whom these figures were submitted

MICHIGAN

State Medical Election—Dr Henry A Luce, Detroit, was chosen president-elect of the Michigan State Medical Society at its annual meeting in Grand Rapids, September 27-30, and Dr Henry Cook, Flint, was installed as president. The seventy-third annual meeting of the society will be held in Detroit Sept 19-22, 1938

Society News—Dr Carey P McCord, Detroit, addressed the Kent County Medical Society in Grand Rapids, October 13, on occupational diseases.—The West Side Medical Society, Detroit, was addressed, October 7, among others, by Drs Ernest H Watson on "Current Status of Sulfanilamide Therapy," and John H Cobane, "Treatment of Seborrheic Dermatitis and Epidermophytosis."—Dr Frederic Schreiber, Detroit, discussed "Cerebral Anoxemia" before the Wayne County Medical Society, Detroit, October 18.—Dr Charles Leslie Mitchell, Detroit, discussed "Back Pain" before the Washtenaw County Medical Society in Ann Arbor, October 12.—Dr Louis H Newburgh, Ann Arbor, addressed the Kalamazoo Academy of Medicine, October 19, on "Nature and Management of Nephritic Edema"

Personal—Dr John C Bugher, assistant professor of pathology, University of Michigan Medical School, Ann Arbor, has resigned to join the staff of the Rockefeller Institute for Medical Research, New York. He will be engaged in research at the institute until January, when he will sail for Bogota, Colombia, to study yellow fever.—Dr George A Kamperman, formerly professor of gynecology, Wayne University College of Medicine, Detroit, was awarded the honorary degree of master of science at the opening exercises of the eighty-eighth session of the University of Michigan Medical School. The Sternberg Medal, awarded annually to the student with the best record in preventive medicine, was presented to Dr Carl A Moyer, an intern in the department of surgery.—Dr Martin A Mortensen, Battle Creek, was guest of honor at a farewell dinner, October 5, given by the Calhoun County Medical Society. He is leaving Battle Creek to live in California. Dr Stanley Gibson, associate professor of pediatrics, Northwestern University Medical School, Chicago, addressed the meeting on "Diagnosis and Abdominal Conditions in Children."—Dr Edwin H Place, Burlington, Iowa, has been appointed health officer for Midland County, succeeding Dr Leslie V Burkett, Midland, who has accepted a similar position in Genesee County

MISSISSIPPI

Community Hospital Opened in Tupelo—The North Mississippi Community Hospital was opened at Tupelo October 3. This fifty-bed hospital is the eighth built as part of a special project of the Commonwealth Fund of New York, which is now undertaking to provide one new hospital each year for a predominantly rural community which will agree to meet its share of costs and to run the institution in accordance with generally accepted standards. The ninth hospital is now under construction at Ada, Okla, and the tenth has been awarded to the community centering in Provo, Utah. The fund began this project in 1926 as an experiment in meeting the need of rural communities for better medical and other health services. The present plan is to aid in establishing hospitals of between twenty-five and fifty beds, easily accessible to a rural community having a population large enough to make good use of such accommodations and capable of meeting operating costs. The hospital may either be a totally new institution or may replace existing facilities which are clearly inadequate. The fund furnishes plans, specifications and architectural supervision for the construction and not less than \$200,000 as a contribution toward capital costs. Communities needing a fifty bed hospital are required to raise from \$40,000 to \$60,000 for their share of the capital cost and must provide in addition a site (with service connections) and from \$10,000 to \$15,000 to meet the deficit of the first year's operation. Ownership and administrative responsibility are lodged in a local corporation, organized not for profit which contracts with the fund to operate the hospital in agreement with specified standards. Hospitals founded under this program are now

operating in Murfreesboro, Tenn., Farmville, Va., Glasgow, Ky., Farmington, Maine, Wauseon, Ohio, Beloit, Kan., and Kingsport, Tenn.

MISSOURI

Society News—Dr Karl A Menninger, Topeka, addressed the Jasper County Medical Society in Joplin, October 12, on "The Emotional Factors of Hypertension"—A clinic on arthritis was presented before the St. Louis Medical Society, October 26, by Drs Ralph A Kinsella, James Archer O'Reilly and Raymond O Muether

NEW JERSEY

Cancer Week in Passaic County—During the week of October 11 the Passaic County Medical Society sponsored a "Cancer Week" in Paterson. Two evening symposiums for the medical profession were presented: one on cancer of the stomach by Drs Fred W Stewart, George T Pack and Ralph E Herendeen, New York, the other on cancer of the colon by Drs Paul Klemperer, New York, and Frank H Lahey, Boston. Dr Frank E Adair, New York, lectured to the public one evening. Round table discussions were held each afternoon, led by Drs Louis G Shapiro, Norman M Dingman and William Spickers. There were also exhibits both for the physicians and for the public, including motion pictures.

Society News—At a meeting of the Essex County Medical Society, Newark, October 14, the speakers were Dr Chester R Brown, Kearney, on "Child Welfare", Dr Richard H Dieffenbach, "Empyema," and Clara H Krauter, principal of the Essex County Girls' Vocational School, "Training for Nursing Attendants"—Drs David M Davis, Philadelphia, and Joseph C Lovitt, Camden, addressed the Camden County Medical Society, October 5, on "Anterior Poliomyelitis with Special Reference to Early Diagnosis" and "Visual Examination of the Urine as a Guide to Urologic Diagnosis" respectively—Dr Arthur M Master, New York, addressed the Hudson County Medical Society, Jersey City, October 5, on "Prognostic Factors in Coronary Thrombosis"—Drs Henry H Kessler, Newark, and Charles Murray Gratz, New York, addressed the Bergen County Medical Society, Hackensack, October 12, on "Cineplastic Surgery" and "Facial Adhesions as a Cause of Pain" respectively—Dr Joseph Stokes Jr, Philadelphia, addressed the Burlington County Medical Society, Moorestown, September 9, on "Newer Knowledge Concerning Influenza"—Dr Norman H Jolliffe, New York, addressed the Passaic County Medical Society, Paterson, September 9, on "The Clinical Importance of Avitaminosis"

NEW YORK

Society News—Dr Stanley P Reimann, Philadelphia, addressed the Ulster County Medical Society, Kingston, October 21, on "Secondary Lesions of the Breast"—Dr Julius H Hess, Chicago, addressed the Onondaga Medical Society, Syracuse, October 28, on "Early Care of Premature Infants and Their Later Physical and Mental Development"—Dr Werner J Rose, Buffalo, addressed the Chautauqua County Medical Society, Cassadaga, September 15, on "Conditions Above and Below the Diaphragm that Simulate Heart Disease"—Dr Clarence J H Durshordwe, Buffalo, and Amos G Stiker, DDS, Addison, addressed the Steuben County Medical Society in Hornell, September 9, on "New Uses of Oxygen" and "Surgery for Immediate Dentures" respectively.

First Pneumonia Institute—The first of five pneumonia institutes sponsored by the state department of health and the Medical Society of the State of New York was held in Syracuse, October 12, with an attendance of fifty for the full program and about forty who attended the lectures but could not be admitted to the clinics and demonstrations for lack of space. The morning session was given over to lectures on the following subjects: "Early Clinical Diagnosis of Pneumonia," "Bacteriologic Diagnosis of Pneumonia," "Oxygen Therapy" and "Serum Therapy of Pneumococcus Pneumonia." The speakers were Drs Edward C Reifenshein Sr, Oliver W H Mitchell and Orren D Chapman, Syracuse; David D Rutstein, Albany, and Jesse G M Bullowa, New York. There were clinical demonstrations of these points, followed by a clinic on treatment showing results of serum therapy. The general sessions were held at the Syracuse Memorial Hospital and the demonstrations at both the hospital and the Syracuse University School of Medicine. It is planned that another institute will be held in Syracuse for physicians who could not be accommodated at the first one. Other institutes will be held in Rochester, Buffalo, Albany and New York City.

New York City

Hospital News—Dr Russell M Wilder, Rochester, Minn., gave a lecture October 19 at Mount Sinai Hospital on "Treatment of Addison's Disease with Salts of Sodium and a Restricted Intake of Potassium"—Dr Leo M Davidoff has been appointed director of surgery at the Jewish Hospital in Brooklyn.

New Beth David Hospital Dedicated—A new million dollar building for Beth David Hospital at 161 East Ninetyth Street was dedicated October 17. The new building, which has ten stories and will accommodate about 200 patients, was opened for patients October 27. Mr Samuel G Ascher, superintendent for the past four years, has been made executive director. The hospital was formerly at Lexington Avenue and One Hundred and Thirteenth Street.

Diseases Under Investigation at Rockefeller Institute—The Hospital of the Rockefeller Institute for Medical Research announces that certain diseases are now under investigation and suitable patients may be referred by physicians and others interested. No charges are made for treatment, room, board or other services. Physicians should communicate by telephone or personal application before sending patients. The diseases are as follows:

Diseases of the blood: Aplastic idiopathic pernicious or severe megaloblastic anemia; sprue or severe glossitis and stomatitis without anemia. Nephritis: Nephritis in initial acute stages and nephrosis in children especially desired.

Heart disease: Advanced heart failure in all age groups but especially in older patients.

Rheumatic fever: Any early acute form also acute sore throat hemolytic streptococcus infections in rheumatic patients.

Chickenpox and measles: Measles in preeruptive stage; chickenpox encephalitis following infectious diseases.

Acute lobar pneumonia and bronchopneumonia in adults.

Society News—Drs Paul C Swenson and Ross Golden addressed the New York Roentgen Society, October 18, on "Neoplasms" and "Infections and Deficiency States" respectively—Speakers at a meeting of the New York Pathological Society October 28 were Drs Andrea Saccoccia and Abraham Rosenthal, on "Colostrum Cell Sarcoma of the Breast", Richard Lewisohn, "Effect of Subcutaneous Injections of Concentrated Spleen Extracts on Mouse Sarcoma 180" and Paul Klemperer, "Chronic Intrahepatic Obliterating Cholangitis"—The first lecture to the public in the third annual series of the New York Academy of Medicine was delivered October 28 by Dr Francis R Packard, Philadelphia, entitled "From Barber-Surgeons to Surgeons"—Dr George G Orstein delivered a Friday afternoon lecture before the Medical Society of the County of Queens, October 15, on "Pathogenesis of Pulmonary Tuberculosis, Its Importance in Diagnosis and Therapy"—The section on laryngology, rhinology and otology of the Medical Society of the County of Kings will present a special program on "Problems of the Hard of Hearing," November 10, with addresses presenting the practical, educational and legislative points of view. There will also be exhibits and demonstrations of instruments and lip reading.

OHIO

Personal—Dr Arthur W Thomas, Ashtabula, has been appointed chief of the bureau of child hygiene and maternal welfare, state department of health, to succeed Dr Abram L. Van Horn, who resigned several months ago. Dr Thomas graduated from Ohio State University College of Medicine in 1914—Dr Carl J Wiggers, Cleveland, has returned from a tour of the Orient, where he delivered a series of lectures at Canton, Hong Kong, Shanghai, Peking, Seoul, Kyoto and Tokyo—Dr Claude S Beck, Cleveland, received the honorary degree of doctor of science from Franklin and Marshall College, Lancaster, Pa., October 3.

Society News—Clarence Cook Little, SeD Bar Harbor, Maine, addressed the Academy of Medicine of Cincinnati October 12, on "Recent Advances in Biological Research on Cancer"—Dr Charles G Johnston, Detroit, addressed the Academy of Medicine of Toledo and Lucas County, Toledo, October 1, on "Treatment of Intestinal Obstruction by Means of the Alka-Tube"—At a meeting of the Summit County Medical Society, Akron, October 5, Dr Marion A Blankenhorn, Cincinnati, made an address on "Modern Treatment of Pneumonia"—At the first fall meeting of the Montgomery County Medical Society, Dayton, October 1, the speakers were the following: all of Cleveland: Drs Walter J Zeiter, on "Clinical Applications of the Newer Developments in Physical Therapy"; Everett N Collins, "Diseases of the Colon and Rectum"; Jones, "Surgical Treatment of Diseases of the Colon."

OKLAHOMA

Special Meeting of Delegates—A special meeting of the house of delegates of the Oklahoma State Medical Association was held in Oklahoma City November 3 to consider pending medical legislation

Society News—Drs Evans E Talley and Alfred J Metscher, Enid, addressed the Garfield County Medical Society, Enid, September 30, on "Diseases of the Thyroid Gland" and 'Management of Cross Eyes' respectively—Drs C J Fishman and Jess D Herrmann, Oklahoma City, addressed the Okmulgee County Medical Society, Okmulgee, September 27, on "Complications and Sequelae of Head Injuries"

OREGON

Society News—Dr Frederick Lemere, Seattle, addressed the Central Willamette Medical Society, Newport, September 4, on "Insulin Shock Treatment of Psychosis"—Dr George F Cooper, San Francisco, addressed the Lane County Medical Society, Eugene, September 17, on "Treatment of Pneumonia"

State Medical Election—Dr Charles E Sears, Portland, was chosen president-elect of the Oregon State Medical Society at the annual meeting in Salem, October 21-23, and Dr Charles T Sweeney, Medford, was inducted into the presidency. The following vice presidents were elected: Drs William W Baum, Salem, Richard B Adams, Portland, and Dean P Crowell, North Bend. Dr Morris L Bridgeman, Portland, was reelected secretary

PENNSYLVANIA

Personal—Dr Gilmore Pontius, chief surgeon, Lancaster General Hospital, Lancaster, received the honorary degree of doctor of science from Franklin and Marshall College, Lancaster, October 3—Dr William Moore Guilford, Lebanon, will be 105 years old November 26. Dr Guilford graduated from the University of Pennsylvania School of Medicine in 1852

Philadelphia

Personal—Dr Karl M Houser, assistant professor of otolaryngology, University of Pennsylvania School of Medicine, received the honorary degree of doctor of science from Franklin and Marshall College, Lancaster—Dr Charles A E Codman has been elected president of the Philadelphia Institute of Medical Research to succeed the late Dr Judson Daland. Dr Codman was one of the group that founded the institute in 1923

Dr Daland Leaves Bequest for Foundation—Dr Judson Daland, who died August 14, left the bulk of his estate to the American Philosophical Society to endow "The Judson Daland Foundation for Research in Clinical Medicine." Ten per cent of the income is to be added to the principal each year. About \$35,000 from the estate is provided for personal bequests. Dr Charles A E Codman received first choice of Dr Daland's medical books and papers and the Philadelphia County Medical Society the second choice. The society also received a bronze bust of Dante. An inventory filed October 4 listed the estate at \$359,507, exclusive of realty

Society News—Among speakers at a meeting of the Philadelphia Allergy Society, October 27, were Drs Herman Gold Chester, Pa., on "Active Immunization of Allergic Patients Against Tetanus and Follow-Up Study" and John A Murphy, 'Propadrin Hydrochloride in the Treatment of Allergic Manifestations'—Speakers on the program of the Philadelphia Academy of Surgery, November 1, were Drs Thomas A Shallow and William T Lemmon, on 'Benign Tumors of the Stomach'; Norman E Freeman, Philadelphia, and Irvine H Page, Indianapolis, "Prevention of Shock from Hemorrhage by Total Sympathectomy"; Eldridge L Eliason and John Paul North, 'Morbidity of Cholecystectomy'

Pittsburgh

Society News—Drs George J Feldstein and William H Clark addressed the Pittsburgh Pediatric Society October 15 on 'Amaurotic Family Idiocy' and 'The Use of Irradiated Milk in Infant Feeding' respectively—Dr Alice Hamilton, Boston, was the guest speaker before the Allegheny County Medical Society October 19 on 'New Developments in Industrial Poisons'. Drs James Leroy Foster and Joseph M Cameron presented papers on 'Reasons for Failure to Diagnose Syphilis in the New Born and Facial Neuralgias Causes and Treatment' respectively. A motion picture on 'Human Sterility' prepared by Drs Paul Titus Benjamin R Ahnquist Ralph E Tafel and Robert H McClellan was shown

SOUTH CAROLINA

Society News—At a meeting of the Seventh District Medical Society at Cain's Mill near Sumter September 9 the speakers were Drs Thomas Preston White, Charlotte, N C, on "Chronic Arthritis and Its Treatment", Thomas C Davison, Atlanta, "Treatment of Gouters", Joseph H Cannon, Charleston, "Congestive Heart Disease," and Rupert H Fike, Atlanta, cancer—Drs George R Wilkinson and John F Ramey, Greenville, addressed the Greenwood County Medical Society, September 30, on "Abdominal Manifestations of Cardiac Disease" and 'Extracardiac Causes of Heart Failures' respectively

SOUTH DAKOTA

Faculty Changes at Medical School—The University of South Dakota School of Medicine, Vermillion, announces several changes in the faculty. Einar Leifson, Ph D, formerly instructor in bacteriology at Johns Hopkins University School of Medicine, Baltimore, has been appointed professor of bacteriology, succeeding Charles A Hunter, Ph D. William H Waller, Ph D, recently instructor in anatomy at George Washington University Medical School, Washington, D C, is professor of anatomy, succeeding C M MacFall, Ph D, and John T Manter, Ph D, recently at Columbia University, New York, is assistant professor of anatomy. H Morrow Sweeney, Ph D, formerly instructor in physiology, Tulane University of Louisiana School of Medicine, New Orleans, is head of the department and professor of physiology, succeeding Harry V Atkinson, Ph D, who is now professor of pharmacology and materia medica

TEXAS

Changes in the University Faculty—Among recent changes in the faculty of the University of Texas School of Medicine, Galveston, the *Texas State Journal of Medicine* reported the following resignations: Drs Frances J L Blasingame, assistant professor of anatomy, John F Pilcher, associate professor of pathology, and J John Westra Jr, Ph D, assistant professor of physiology. Dr Samuel R Snodgrass, Franklin, Ind, has recently been appointed assistant professor of neurosurgery

Personal—Dr Louis R Brown, Little Rock, Ark, has been appointed superintendent of the Galveston State Psychopathic Hospital, succeeding Dr Giles W Day. A new addition to the Galveston hospital providing for forty-five patients was recently opened—Dr Brooks Stafford, Angleton, has been appointed health officer of Brazoria County to succeed the late Dr Samuel B Maxey—Dr Samuel J Pate, Woodville, was honored with a testimonial dinner September 2 given by physicians of Woodville and Beaumont, where he practiced for many years. Dr John A Hart, Beaumont, was toastmaster

Society News—Drs Alfred L Hathcock, Palestine, and Harry M Spence, Dallas, addressed the Henderson County Medical Society, Athens, September 6, on "Sarcoma of the Uterus" and 'Frequency of Urination in Women' respectively—Drs Thomas M Oliver and Horace T Ayneworth, Waco, were the speakers at a meeting of the McLennan County Medical Society, Waco, September 14, on "Advances in the Treatment of Varicose Veins" and "ABC's of Electrocardiography" respectively—At a meeting of the Tarrant County Medical Society, Fort Worth, September 7, the speakers were Drs Clarence C Garrett on 'Heat Exhaustion', James H Hook, 'Pohomvelitis' and John W Tottenham Jr "Immunizing Blood Transfusions"—The Dallas Southern Clinical Society will hold its tenth annual clinical conference, March 14-17 1938, at the Adolphus Hotel—Dr Samuel A Shelburne among others addressed the Dallas County Medical Society, October 13, on 'The Rational Use of Acacia in the Management of the Nephrotic Syndrome'

VIRGINIA

Personal—Dr Charles L Savage Richlands, has resigned as health officer of Tazewell, Buchanan and Russell counties—Dr Edward N Schilling, chief medical officer of the Veterans Administration Facility, Kecoughton, has been transferred to Atlanta as chief medical officer of the Veterans Administration Facility there it is reported

WEST VIRGINIA

Society News—Dr Hugh H Trout Roanoke, Va, addressed the Kanawha Medical Society September 14 in Charleston on 'Varicose Ulcers'—Dr James Torrance Rugh Philadelphia addressed the Ohio County Medical Society, Wheeling October 8, on 'Some Problems of the Lower Part

of the Back"—The Hospital Association of West Virginia held its annual meeting in Wheeling, October 7-8—Dr Curtis F Burnam, Baltimore addressed the Harrison County Medical Society, Clarksburg, September 2, on cancer of the uterus

WISCONSIN

Memorial Lecture by Dr Gross—Dr Louis Gross, New York, delivered the Lippitt Memorial Lecture at Marquette University School of Medicine, Milwaukee, October 15, on "Considerations Concerning Coronary Occlusion" Dr Gross was one of the seventeen persons killed in the crash of the airplane *Mauliner* in Utah October 17

University News—Dr Everett D Plass, Iowa City, addressed the University of Wisconsin Medical Society, Madison, in a joint meeting with the medical school preceptors October 15 on "Polyneuritis of Pregnancy" Dr William Snow Miller, emeritus professor of anatomy, made an address October 21 on "Some Vital Points in the Architecture of the Lung"

PHILIPPINE ISLANDS

Society News—At a meeting of the Manila Medical Society recently the speakers were Drs Honoria Acosta-Sison and Juan S Galang, on "Chorionepithelioma with Report of Six Recovered Cases" and Dr Pablo Anzuers, "Is Therapeutic Abortion Legal?"

GENERAL

Americans at International Congress—Thirty-seven American physicians attended the International Congress on Hepatic Insufficiency in Vichy, France, September 16-18 The following presented papers Drs Anthony Bassler, New York, Lathan A Crandall Jr and Andrew C Ivy, Chicago, Norman W Elton, Reading, Pa, and Hyman I Goldstein, Camden, N J, all speaking on "Hepatic Insufficiency in Its Relation to General Nutrition and Especially to the Nervous System"

Society News—Dr Robert Tart McKenzie, Philadelphia, was elected president of the Academy of Physical Medicine at the annual meeting in Philadelphia, October 19-21, Drs Roland A Case, Cleveland, and William H Schmidt, Philadelphia, were elected vice presidents, and Dr Herman A Osgood, Boston, was reelected secretary—The Pacific Coast Society of Obstetrics and Gynecology held its annual meeting in San Francisco, November 3-6—The Society for the Study of Asthma and Allied Conditions will hold its fall meeting at the Waldorf-Astoria Hotel, New York, December 11 Dr William C Spain, 116 East Fifty-Third Street, New York, is secretary

Research Fellowships Available—The National Research Council announces that fellowships in the medical sciences will be available for the year beginning July 1 1938 These fellowships are open to citizens of the United States and Canada who have the degree of doctor of medicine or doctor of philosophy The announcement notes that the fellowships are intended for recent graduates and not for persons already professionally established Applications must be filed on or before Jan 1, 1938, and fellows will be appointed at a meeting of the medical fellowship board about March 1 For further information address the secretary of the Medical Fellowship Board, National Research Council, 2101 Constitution Avenue, Washington, D C

New Officers of Radiological Societies—Dr Raymond G Taylor, Los Angeles, was chosen president-elect of the Radiological Society of North America at its recent annual meeting in Chicago, and Dr Howard P Doubt Detroit was installed as president Dr Donald S Childs, Syracuse, N Y, is the secretary Dr John W Pierson, Baltimore, was named president-elect of the American Roentgen Ray Society and Dr Byrl R Kirklin, Rochester, Minn, was installed as president Dr Carleton B Peirce, Ann Arbor, Mich, was chosen secretary The next annual session will be held at Atlantic City, probably Sept 20-23, 1938 New officers of the American College of Radiology include Drs James M Martin, Dallas, Texas, president, and Eugene P Pendergrass, Philadelphia, secretary

Fellowships in Psychiatry—The National Committee for Mental Hygiene has available a limited number of fellowships for training in extramural psychiatry provided by the Commonwealth Fund and other sources Fellows will be assigned for one or two years to a selected child guidance clinic the term and plan of the fellowship to be determined by the peculiar needs of the fellows Candidates for fellowship awards

should have had at least two years of psychiatry in an approved mental hospital service, in addition to other qualities fitting them for extramural service This provision of training fellowships comes in response to a definite paucity of personnel in this field, the announcement stated Requests for further information about these fellowships, and applications therefor should be addressed to Dr George S Stevenson, The National Committee for Mental Hygiene, room 822, 50 West Fifty-first Street, New York, N Y

Impostor Impersonates Pathologists—Several pathologists have recently reported that a man posing as a pathologist has been using the name of Dr Eustace L Benjamin, associate professor of pathology at Northwestern University Medical School, Chicago, to obtain money through fraudulent checks Dr Emmerich von Haam, Columbus, Ohio who first reported cashing a check for the man in the belief that he was Dr Benjamin, says that the impostor has since called himself Dr von Haam and Dr Simonds of Chicago Whatever name he uses, he refers to other pathologists as his close friends He is familiar with medical terminology and has a fair knowledge of laboratory methods This man is about 40 years old, of average size, with dark eyes and hair tinged with gray His neck is short and thick, his face is round and his small eyes bulge somewhat Dr Benjamin reported that he cashed a check during the past winter for this man who at that time said he was a pathologist from Mercy Hospital, Canton, Ohio Checks for amounts ranging from \$10 to \$100 have been cashed for him by pathologists in several laboratories

CANADA

Graduate Course at Dalhousie—A refresher course in medicine and surgery was presented at Dalhousie University Faculty of Medicine, Halifax, N S, for a week beginning August 30 The instructors were Drs Howard M Clark, Boston, on "Management of Abdominal Emergencies", Leo Kanner, Baltimore, "Modern Trends in Psychiatry" and Richard A Kern, Philadelphia, "Clinical Allergy" and "Duodenal Ulcer"

Society News—Dr Alfred Howard Spohn, Vancouver addressed a meeting of the Vancouver Medical Association October 5, on "Conditioned Reflexes and Their Relation to Medical Practice"—Dr Charles H Hair delivered his inaugural address as president of the Academy of Medicine of Toronto, October 5, on "How Medicine Is Influenced by Economic Conditions"—The North Pacific Society of Internal Medicine held its fall meeting in Victoria, B C, with Dr Edwin G Bannick, Rochester, Minn, as guest speaker, on nephritis, blood sedimentation tests and sulfanilamide therapy

The Poliomyelitis Epidemic in Ontario—A summary of the recent outbreak of poliomyelitis in Ontario, published in the October issue of the *Canadian Public Health Journal* states that 2,180 cases were reported in the province from January 1 to October 2 The largest number in any one week was 413 for the week ended September 4 There were 697 cases in Toronto The provincial health department has records of 450 cases in which there is some degree of paralysis or weakness For treatment of these patients a special orthopedic hospital has been opened in Toronto with accommodations for 100 children Three weeks' free treatment is given Twenty-three respirators have been made available with funds provided by the provincial health department

Deaths in Other Countries

Sir John W Thomson-Walker, consulting urologist and emeritus lecturer on urology, King's College Hospital, London Hunterian professor, Royal College of Surgeons of England 1907, author of various publications on urology president of the fifth International Congress of Urology, died October 6 in Aviemore, Inverness-shire, Scotland, aged 60—**Sir John W Moore**, formerly professor of the practice of medicine Royal College of Surgeons in Ireland author of textbook, and for many years editor of the *Dublin Journal of Medical Science* former president of the Royal Academy of Medicine in Ireland and of the Royal College of Physicians of Ireland died October 12, aged 91

CORRECTION

Assistant Professor of Orthopedics—Dr Jesse T Nicholson has been promoted to assistant professor of orthopedics in the Graduate School of Medicine University of Pennsylvania and not assistant professor of obstetrics as noted in THE JOURNAL, October 23 page 1372

Oct 9, 1937

The British Medical Association and the Public

The British Medical Association has made a new departure. A special meeting of the council was convened to consider a memorandum of proposals for organizing public opinion on behalf of the association and improving the public relations of the medical profession generally. It seems to the council that although individual members of the public have, as a general rule, high regard for their own physicians, the public as a body is often suspicious and critical of the medical profession as a whole and of the British Medical Association in particular. Physicians are nervous when they are in trouble, as when charged with drunkenness, when they appear in the divorce court or when charged with negligence. The public is in great measure ignorant of the work of the association's on medico-social problems. It is reminded of the national health insurance service only when a defaulting physician is fined, it knows nothing of the association's plan for the extension and amplification of this service or for an improved maternity service. The council is advised that the association can apply propaganda and advertisement without compromising the dignity or status of the profession. The objectives would be to instruct and improve public opinion regarding physicians, to enlighten the public regarding the work of the medical profession, to advise the press to be more constructive and less destructive, more informative and less irresponsible in handling its news regarding physicians and the association. The council decided to establish a propaganda fund to be financed from the association funds and by the trustees of the national insurance defense fund for a period of three years. There will be a propaganda committee and a public relations officer.

Sciatica Due to Prolapse of an Intervertebral Disk

Sciatica due to prolapse of an intervertebral disk is a condition that has only recently been recognized. At a meeting of the Section of Orthopaedics of the Royal Society of Medicine, Mr Norman L Capener reported a case which he had cured by laminectomy. He referred to a paper which he had read at a meeting of the British Orthopaedic Society in 1934, when he discussed the influence of certain spinal movements on the cause of sciatica. As the result of radiologic studies of normal spines he stated that sciatica due to compression stresses on nerve roots was more apt to occur in hyperextension but that traction stresses were most likely to be the cause of trouble when the lumbosacral spine was hyperflexed. He then demonstrated the opening up posteriorly of the intervertebral interval in hyperextension and remarked on the ease with which prolapse of the nucleus pulposus could occur in this position. He now said that most cases of traumatic sciatica occur with a force exerted in the flexed position, which is often associated with the lifting of heavy weights. It was easy to understand the possibility of a portion of the disk being extruded like a pea out of a pod.

A railway engine driver, aged 41, sprained his back at work in August 1935 and soon began to suffer severe pain in the right buttock and thigh, which was increased after exertion but relieved by lying down. When seen in September he had typical right-sided sciatica with homolateral scoliosis, rigid lumbar spine, gluteal wasting and diminished Achilles reflex. There were no sensory changes. X-ray examination was negative. For six months he received the usual conservative treatment—radiant heat, massage, plaster jacket, sciatic nerve stretching, epidural injections and manipulations under an anes-

thetic—all without lasting improvement. In the summer of 1936 the sciatica became much worse and involved the opposite side.

Oct 30, 1936, lumbar puncture was performed at the level of the third and fourth lumbar vertebrae. The pressure was found normal and the usual rise occurred on jugular compression. Procaine hydrochloride solution was injected into the epidural space and produced a small rise in intrathecal pressure, which did not correspond to the amount injected, suggesting partial spinal block. Two days later 5 cc of iodized oil was injected into the theca at the first lumbar interspace and radiography strongly suggested a constriction of the theca arising from the front of the canal in the region of the disk between the fourth and fifth lumbar vertebrae. The injection produced severe pain, which had to be relieved by a further lumbar puncture.

November 12, laminectomy was performed on the fourth and fifth lumbar and first sacral vertebrae. The constriction mentioned was confirmed: there was no pulsation below this level, and the posterior projection of the disk was verified. Moreover, the constriction of the dura appeared to be circumferential. This was widely opened up in the middle line, the disk was not interfered with and the wound was closed. After recovery from the operation the patient had immediate and complete relief, and all signs of sciatica disappeared. He resumed his usual work, which involved coaling the furnace.

PARIS

Oct 9, 1937

Second International Gastro-Enterologic Congress

The second Gastro-Enterologic Congress was held September 13 at the Faculté de médecine. More than 600 specialists from thirty-five foreign countries attended the meeting. Prof M Loeper was president of this year's congress and introduced Prof Pierre Duval, who called attention to the necessity of team work between surgeons who specialize in gastro-intestinal surgery and gastro-enterologists who make the diagnosis and carry on the after-treatment. The first question to be discussed was early recognition of gastric cancer, of which the clinical and serologic aspects were the subject of a paper by Carnot and Caroli. They said that the diagnosis was usually made too late so that removal is impossible in three fourths of the cases when exploratory laparotomy is performed. This is often due to the latent character of the initial symptoms. In one third of the cases, the onset dates back about five months from the time at which the patient is first seen. The only way in which the high percentage of inoperability can be reduced would be the routine use of x-ray examination in all suspicious cases. A fourth of the patients neglect to have this done in spite of a history of digestive disturbances of long duration. There is nothing pathognomonic about the early symptoms. Anorexia is observed in only 14 per cent of patients and the pain is usually relieved by medication. The question of age has been found to be of no importance. Familial antecedents may be of some help in the clinical history. The difficulty of making an x-ray diagnosis was emphasized and the problem which presents itself is as to whether an ulcer exists which has undergone malignant changes or whether the symptoms are terminal and indicative of a phase of inoperability. Ulcerating cancers are more common than any other type.

This paper was followed by one on x-ray diagnosis by Rene Gutmann who believed that an early diagnosis can be made if serial films are made as a routine and are correctly interpreted. At its very onset, cancer of the stomach cannot be recognized radioscopically so that this method alone does not suffice. On the other hand films that show rigidity of the stomach contour indicate an infiltrating type of cancer whereas a niche is found in the ulcerative, tumor-forming and vegetant types.

In one out of five cases, Gutmann and Bertrand were able to trace the change from a benign to a malignant form of ulcer. The ulceriform cancer has the appearance of a niche with sharply demarcated borders. In these, one finds the Carman meniscus sign. The evolution of such niches must be followed at repeated examinations. The therapeutic test consists in intravenous protein treatment. If the x-ray signs persist, immediate operative intervention should be advised. The pathologic anatomy, physiopathology and biochemistry and the value of gastroscopy and of gastrophotography in cancer of the stomach were the subjects of papers by Cagnetto of Italy, Bottin of Belgium, Felsen of the United States, Moutier of Paris and Garin and Bernau.

Bertrand of Paris reported on the aspects of ulcers developing into cancers based on microscopic studies when taken in conjunction with x-ray observations.

Charrier and Gatellier pointed out that it is impossible for a surgeon on examination of the stomach, at operation, to differentiate between a benign and a malignant ulcer.

Gosset and Duval in their general conclusions based on all the preceding papers stated that (a) clinical signs and the evidence yielded by gastric chemistry were inadequate for diagnostic purposes, (b) direct (at operation) and gastroscopic examinations are deceptive, (c) only the microscopic and x-ray examinations and therapeutic tests are of any value. If there is an association of amelioration of symptoms and of x-ray evidence, this speaks for the benignity of the lesion. If there is amelioration of the symptoms but persistence of x-ray signs, this speaks for probable malignancy, hence the key to the situation consists in repeated x-ray and clinical examinations.

Katsch, Prevot, Henning, Buerger, Staemmler and Konjetny, all German delegates to the congress, emphasized the important part played in the etiology of gastric cancer by a preceding or concomitant gastritis when associated with adenomas or polyps, which were frequently found in their cases.

Examination of Applicants in Transportation Services

One of the most interesting exhibits in this year's Paris Exposition is that of the psychotechnical department of the French transportation, urban and railroad, services. The tests given to applicants for positions as bus or street car motormen and locomotive, oil and steam propelled, engineers reveal the progress made in the last twenty years in the application of information obtained through studies in psychologic laboratories to commercial work.

A monograph has just appeared on the Paris experience by J. M. Lahy, published by Dunod. In the preface, the director of the technical division of the Paris transportation services (motor busses and subways), Mr. Bacquerisse, states that the medical examination of applicants aids in eliminating those whose cardiovascular and other conditions which will not permit heavy physical exertion and other physical defects, but only psychologic tests, will be able to exclude from work as signal tower operators those individuals who are unable to concentrate or who fatigue mentally too rapidly. The Paris transportation services employ more than 30,000 men and women (many of the latter as omnibus conductors). Scientific selection of applicants has effected an economy of more than a million francs a year. Psychotechnology is a comparatively recent science which studies how to reduce the expenditure of nervous energy, necessarily associated with every physical effort. It also aims to increase mental activity without too much of a drain on the nervous system. The limit or threshold so to speak, at which signs of mental fatigue appear is not a uniform one but is subject to individual variations. To attain the maximum return with a minimum of effort the primary condition to realize is that every worker should be mentally equipped to carry out his particular task. If he is capable of doing this in several tasks selection must be made of the one for which the applicant has the greatest aptitude.

Variations in muscular activity have a narrower range than to five or six, than those of mental activity, which vary from one to several millions. It is a mistake to think that the constant repetition of some small movement, if not followed by fatigue, is an adequate criterion of mental fitness, because in actual practice the length of time and rhythm necessary to execute it is always determined in advance. Certain individuals show signs of mental fatigue when called on to execute easy but monotonous tasks more than others. The man who is in charge of a railroad signal tower must be able to react quickly and be possessed of a good memory. Methods employed to determine professional aptitude should be objective, i. e., studied graphically.

In France, these methods have been studied during the past twenty years in the laboratory for experimental psychology of the Ecole pratique des hautes études and more recently in the psychotechnical laboratories of the French transportation services. The results of the examinations of more than 10,000 applicants for positions as motormen, signal service operators, and so on, are recorded in the recently published monograph of the director of the latter laboratory, Dr. Lahy.

Social Insurance as Applied to Railroad Employees

When social insurance was first introduced here in 1930 no provision was made for workers employed on railroads. This omission was corrected in 1931, but the rules contain some material differences from those applicable to nonrailroad employees, as follows: (a) Sickness indemnity can be paid only to the individual employee and not for any illness of the wife or husband, as the case may be, or for any illness of the children of the employee. (b) In case of absence for confinements, the worker is entitled to twelve weeks' full pay. (c) In case of illness or confinement, the worker can be cared for only by the company's physician and does not have the right, as in the case of workers not employed on railroads, to select his own medical attendant.

Sept. 13, 1937

International Congress on Graduate Medical Study

The International Congress on Graduate Medical Study was held in Berlin August 21-25. Its objectives were an exchange of information on the conduct of graduate courses in various countries and the world wide promotion of graduate study. In many lands postgraduate medical education has become highly organized. For the last two years members of the German medical profession have been subject to a legislative innovation in this regard, all doctors (with the exception of university docents, directors of the larger hospitals and military and civilian physicians in government service) being required to participate every five years in a graduate course of three weeks' duration (THE JOURNAL, Nov. 9, 1935, p. 1535). Altogether, 300 hospitals in sixty-eight different German cities have been designated as institutions suitable for graduate studies. This wide distribution enables the individual physician to remain near his home while studying and thus the personal expenses entailed are kept within reasonable bounds. Moreover, no tuition fees are exacted for the courses themselves. The question of locum tenentes has shown itself to be the most difficult feature of this system since the employment of a substitute is rather costly to the practitioner. Latterly, however, a system of reciprocal substitution among physicians of each community has been worked out and in addition the placement exchange of the German Medical Association stands prepared to react in any emergency. For the accommodation of doctors in attendance on a course the establishment of a chain of convenient ly located "physicians' homes" has been planned, several of which are already in existence. Of about 40,000 physicians in

Germany, some 25,000 will participate quinquennially in this rotated compulsory study program. The planners of German graduate curriculums have considered it desirable that each student physician should acquire a knowledge of the basic principles involved in the procedures of "nature medicine" so far as the latter have been proved valuable. Acquaintance with the fundamentals of homeopathy is also considered of importance.

At present there are in Germany three academies of graduate medical study and the foundation of a fourth is contemplated. The Berlin academy is to retain its present general character. The Dresden academy will in future concern itself principally with the problem of the integration of "Nature Medicine" within the framework of medical science as a whole. The curriculums of the Hamburg academy will be expanded to include special courses in tropical hygiene, tropical diseases and overseas medicine in general. The fourth academy, to be situated in Munich, will be set aside for a wholly new type of instruction there, in the interest of national health policy, an attempt will be made to bring the therapeutic and prophylactic services of the physician into the closest possible contact with the active worker on the job. Specifically, a doctor enrolled at the Munich academy will be made conversant with industrial physiology and with the so called early lesions of occupational disease and will study the feasibility of prophylactic measures.

Accordingly, one may truly say that in Germany postgraduate medical study, already highly organized, continues to develop.

The transactions of this well attended international congress were characterized by a lively symposium on methods in which the representatives of thirty-six nations participated. Of even greater importance were the papers submitted by eminent university professors on fundamental pedagogic problems of the various specialties. Other delegates provided interesting descriptions of how the organization of graduate medical study was influenced by conditions peculiar to their respective countries. Dr. Wagner, the national fuhrer of physicians, bid the delegates welcome in an address entitled "The Place of the Physician in the New Germany." He dwelt mostly on topics such as the Nuremberg laws against Jewish physicians, the problems of hereditary disease, the new German education and the organization of the National Chamber of Physicians.

Professor Borst of Munich, pathologic anatomist, then discussed "Research and Graduate Study." Speaking from the standpoint of general pathology he spoke of the demands of medical practice and the interrelation of the various specialties. The universities have undergone marked expansion in order to meet the educational standards of the present day. A great scientist, said Borst, should know how to combine strict interpretation of results and his own confident expectation; he should also be able to bring his scientific opinions into harmony with his weltanschauung. Graduate study ought not only to facilitate progress in the specialties, it should also help to explain their interdependence and the importance of each to medical science as a whole. Thus will be avoided that too great preponderance of theory which often tends to obscure the practical application of specialties. Only a doctor who has engaged in research can feel sure of himself in the presence of manifold and varying clinical pictures. The need of a broader outlook differs with the individual physician. According to investigators of the German situation, most physicians could profit by graduate study, and especially by research study.

Dr. Blome described the organization of graduate study in Germany and several of the foreign delegates did likewise for their respective countries: the United States, represented by Dr. Foster Kennedy, France, Austria, Japan, Italy, Switzerland, Latvia and Finland. Special themes were then discussed. Sauerbruch spoke on the graduate education of the surgeon. There was also considerable discussion of the anticancer cam-

paign. Dr. Schraenen, secretary general of the Belgian Anticancer Association, introduced this topic. He was followed by Professor Auler of Berlin, who read the principal paper wherein he discussed the systematic organization of an effective fight against cancer. Various foreign delegates also talked on the cancer problem. Other major topics were occupational and industrial medicine, the graduate study of obstetrics and so on.

One result of this international congress was a resolution passed at a meeting of the delegates from twenty-five countries. It provided for the establishment of an International Academy for Graduate Medical Affairs. A constitution and by-laws for the new organization will be worked out by a committee consisting of Borst of Munich, chairman, Adam of Berlin, secretary general, Bastianelli of Rome, Blome of Berlin, Proctor of London and Roussy of Paris. This international academy will have its permanent seat in Berlin.

The Reaction of Aluminum to Fruit Products

On account of the shortage of raw materials in Germany, the attempt has been made to introduce domestic substitutes for foreign metals, e. g., aluminum for tin. Dr. Reif undertook at the National Health Bureau an investigation to determine to what extent aluminum can supplant other metals used in the handling of food. Experiments were conducted with food-stuffs of an acid character such as apple sauce and plum jam. Two brands of aluminum, one 99.5 per cent and the other 99.8 per cent pure were tested. Numerous experiments showed that the corrosive effect of these acid containing foods on aluminum was particularly dependent on the water and extract content. In general, the metal of 99.8 per cent purity proved its superiority to that of 99.5 per cent. Alloys of aluminum showed themselves the least resistant to the corrosive action of fruit products. Reif does not attempt any medical evaluation of the data. His report is interesting in the light of earlier studies also sponsored by the National Health Bureau and on the basis of which it was concluded that no danger is entailed in the use of aluminum vessels (*THE JOURNAL*, Dec 13, 1930, p. 1849).

AUSTRALIA

(From Our Regular Correspondent)

Sept. 9, 1937

Australasian Medical Congress

Under the presidency of Sir Henry Newland, 450 delegates from Australia, New Zealand and Great Britain attended the 1937 Australasian Medical Congress, held at Adelaide from August 23 to 25. This congress marked the jubilee of such meetings in Australia. The chief features of the congress were the laying of the foundation stone for the Institute of Medical Science in Adelaide and a major discussion on tuberculosis in Australia. At the official opening, the gold medal of the British Medical Association was presented to Sir Henry Newland, who was the fourth recipient since its institution in 1922. Sir Henry had been secretary of the South Australian branch of the British Medical Association from 1909 until 1914 and became president in 1920. He had performed great service for the federal branch and is at present a vice president of the British Medical Association in Great Britain. He was a founder and the first president of the Royal Australasian College of Surgeons. For many years he was lecturer in surgery and operative surgery at the University of Adelaide. In the war he served with distinction.

The main themes in Sir Henry Newland's presidential address were the application of scientific knowledge to human betterment, the influence of heredity on constitutional disease, the aging of the population, the progress of specialism and the possibilities of national insurance in Australia. Medicine so far has concerned itself with the conquest of diseases which have their origin in the environment of man. These are the diseases of infancy and adolescence. It can claim to have saved the

babies But if babies are surviving the environmental diseases, they must die in adult life, or senescence The diseases of the latter half of life are constitutional diseases, that is, breakdowns of the various organ systems which in their combination form the individual Reference was made to the extraordinary growth of specialism The specialist himself often tended to fail to see any point of view but his own To succeed in the pursuit of a specialty, he must concentrate on its literature and technic His concentration would almost inevitably make him narrow in his outlook and a source of danger in general medicine It was therefore of the greatest importance that before a man was fit to limit his practice to a specialty he should be thoroughly trained in general medicine and surgery The surgical specialist of today is cast in a different mould from the surgeon of 100 years ago A surgeon of today must have a knowledge of the biologic, physiologic and psychologic disturbances inseparable from all disease processes Figures were given to show the result of modern care in the reduction of mortality from operations on the kidneys In operations for kidney stones, mortality had decreased from 19 per cent in 1902 to 9 per cent in 1914 and to about 1 per cent in 1924 A recent review showed an average mortality after operation of 4 per cent, and several large series of cases had been reported without a death Figures could be quoted to show similar results in other fields But the changing rate of mortality is not the only change that is taking place in surgery The operation lists of today differ greatly from those of thirty years ago It is of general comfort to know that surgery has become more preservative and less extirpative Indeed, it is paradoxical that the chief aim of the scientific surgeon should be to find ways of avoiding surgery The tendency to say "this organ or that structure is diseased, let us cut it out," is giving place to an attempt to save it

Recognition of the fact that even in a special branch of medicine it was not possible for one man to be the repository of all the knowledge of detail needed for diagnosis and treatment had led to another change That was the development of the unit, or team, system That aimed, without interfering with the practice of bringing the medical student into intimate contact with the patients, at grafting on the well tried English system a means whereby clinical education might be placed on a more scientific basis than had been possible before Not many years ago the governing bodies of the great hospitals considered that it was the duty of the surgeons to do all operations Now it was being realized that the routine operative work could be done as well by the younger men, leaving more time for the seniors to do progressive work

One of the great needs of the present is hospitals in which patients with chronic diseases can be adequately treated and where the disease can be made the subject of intensive research Sir Henry said that one of the great advances of the last fifty years was that the profession had learned to recognize the importance of the prevention of disease as an essential part of a national health service It was recognized now that doctors had a part to play in the attainment of that state of positive good and efficient physical and mental health which was something infinitely better than the mere absence of disease Physical education and mental hygiene should take their place among the great social services as a branch of public health, like housing, sanitation and nutrition, through which it was hoped to achieve a high standard of physical excellence, combined with mental and moral discipline It was of interest to note that the University of Adelaide and the South Australian branch of the British Medical Association had under consideration a suggestion by Sir Stanton Hicks to found a health clinic

Speaking of the probability of the introduction of compulsory national health insurance, Sir Henry said that, for better or worse, national health insurance was now an accepted part of

English life However effective positive means of insuring health and preventing disease might be, there would always be some who would require examination and treatment How effective the contemplated measures would be would depend on whether the insurance scheme had the whole hearted support of the medical profession Whether that support would be forthcoming would depend on the bill to be presented to the commonwealth parliament

With regard to the value of graduate work, Sir Henry said that the necessity for it had been fully recognized by the profession but not, unfortunately, by the universities with one exception—Sydney Was it too much to hope that Melbourne and Adelaide would follow the same enlightened policy? The Royal Australasian College of Surgeons had been active in the cause of postgraduate study and surgical research

TUBERCULOSIS IN AUSTRALIA

A complete review of the problem of tuberculosis as it exists in Australia was the motif of the congress, and it occupied a plenary session This disease claimed in South Australia more than three times as many victims as the total for all other infectious diseases In opening the discussion, Dr M J Holmes, senior medical officer of the Commonwealth Department of Health, showed by a series of graphs that there was a pronounced death rate from tuberculosis in young women in South Australia, rising to 96 per hundred thousand in age group 25 to 29 years compared with 60 for Australia and 50 in New South Wales The mortality rate in age group 20 to 24 years in South Australia (85 per hundred thousand) was about 40 per cent greater than in New South Wales (51) It was thought that the high mortality in young females compared with males might be due to the special stress placed on the body in child bearing and to the strain of present day life The mortality from human tuberculosis of bovine origin was now very low in Australia and had declined much more rapidly than the mortality from tuberculosis of human origin That might be attributed mainly to smaller dosage of infection through the milk supply Deaths from tuberculosis in Australia were almost exclusively due to the human strain of infection Consequently our main object must be the breaking of the human chain of infection Regarding measures for the control of tuberculosis, it was considered essential that all the activities within each state should be under the control of a state director of tuberculosis engaged full time on direction and coordination and given all necessary powers and facilities The clinic system was the foundation on which all effort for the control and eradication of tuberculosis must be based Clinics should reach out into the community to maintain the persistent hunt for the earliest manifestations of the disease There should also be a mobile clinic Early diagnosis was an essential objective of the clinic system The examinations, physical and x-ray, should be periodic and should be most frequent and careful between the ages of 15 and 25 years The high mortality in women from 20 to 30 emphasized the need to look for early evidence in childhood and early adult life

One of the greatest difficulties in the fight against tuberculosis was the economic one of maintaining the family of the tuberculous sufferer in a reasonably good state of nutrition and in a suitable environment The invalid pension paid was utterly inadequate to provide suitable nutrition and environment The position of the tuberculous ex soldier was much better, as the repatriation department provided not only excellent treatment but a good pension It was considered of the greatest urgency that some system of monetary allowance should be established which would provide adequately for the family of tuberculous civilian patients and that the allowance should be paid in full when the patient was under treatment at an institution as well as when he was under treatment in his own home There was a need for accommodation for the patient who has not developed an active focus of disease—the clinical

with a positive tuberculin skin reaction, who was ill nourished or unhealthy, or who for any reason should be removed for a time from any source of possible infection, and whose resistance required building up. Preventoriums formed the essential links in the system for preventing the development of fresh foci of infection in the community, and they should be provided by the state. Last year 2,836 persons died from tuberculosis in Australia. The cost to the commonwealth and state governments in pensions and in treatment was more than a million pounds a year. If tuberculosis mortality had continued at the same rate as in 1880, the governmental expenditure would now exceed five million pounds a year, instead of one million. The success already attained in fighting tuberculosis was therefore saving Australia millions of pounds every year. The eradication of the disease, which is a practical ideal in this country, would save millions of pounds in the future. Measures directed to the total eradication of the disease would cost less over the next twenty years than is spent at present in partially checking the disease. The success already attained by our incomplete and ill balanced methods is an earnest of the infinitely greater success which would follow the persistent application of wholehearted measures. We should aim at nothing less than a commonwealth free from tuberculosis.

Sir Robert Philp teaches his students that the best climate for tuberculosis is that which woos the patient most into the open air. In this respect Australia is fortunate. With our great natural advantages in climate and in a relatively high standard of living, we can look with nothing but dissatisfaction on the existing mortality rate from tuberculosis in Australia. Dr Cotter Harvey, who was the next speaker, was in accord with Dr Holmes. For a campaign to be successful, there were four essentials: an adequate public health organization, a recognition of the part played by the general practitioner, a careful education of the layman, and a thorough education of the medical student in chest diseases. There was need for reform in what was complacently called "sanatorium treatment" in this country, as it had in many cases fallen far below modern standards, although there were some shining exceptions. Contact examination should include all persons with whom the patient had been in close contact. Nor should older people escape examination. Grandfather's so-called bronchitis might have infected many grandchildren. The x-ray survey of selected groups would prove to be the most profitable advance in preventive medicine, provided the utmost care was taken in the interpretation of the films. Finally, the standard of living among the lower classes should be improved and an endeavor made to ensure an adequate diet for all. Tuberculosis was the one disease to which a well fed body was more resistant. Dr Harvey pleaded for a sympathetic consideration by public health authorities and the Australian governments of tuberculosis control. Federal and state governments have had placed before them carefully considered programs by competent authorities, but we still await the day when some practical moves will be made. In this respect Australia is lagging behind most countries, even admitting that our mortality is among the lowest in the world. A continuance of the present policy of apathy and delay in financing a comprehensive campaign against tuberculosis, a preventable disease which in Australia is responsible annually for the deaths of nearly 3,000 persons, more than half of whom are under the age of 45, is not merely a moral crime; it is an economic blunder.

Tuberculosis in man could not be adequately dealt with unless consideration was given to the knowledge gained by study of the disease in the lower animals, said Dr L. B. Bull, director of the Divisions of Animal Health and Animal Nutrition in the Council for Scientific and Industrial Research. All the domesticated animals were susceptible to the disease and it varied in frequency in different species. Man could become infected by the use of animal products as food or he

might himself infect one or more species, which, in turn, might spread the disease among their own species as well as among human society. Tuberculosis was most common in cattle, fairly common in pigs, not uncommon in dogs, but rare in sheep and goats. It was common in birds, particularly in the northern hemisphere, and also affected wild animals in captivity. Outlining the control of tuberculosis in animals, Dr Bull said that systematic tuberculin testing and destruction of infected animals was an ideal method for the eradication of tuberculosis. Dr Harvey Sutton considered that insufficient data were available about tuberculosis, particularly with regard to the number of early cases treated. There should be more information, particularly about infection among medical men themselves.

Cases in which surgical intervention could be employed in the treatment of tuberculosis were discussed by Grey Turner, professor of surgery at the University of London, in his presidential address to the surgical section of the congress. One question that needed more attention, he said, was that of the survival of the activity of disease germs. Cases diagnosed as "swollen glands" might be treated successfully in the youth of a patient and many years afterward the neck might be found to contain glands in a tuberculous state. It could be said sometimes of the tubercle bacillus that it "was not dead but sleepeth." Many of the unexplained deaths of old men were due to general tuberculosis, which had remained a latent infection from infancy.

SHOULD TUBERCULOUS PATIENTS MARRY?

The question whether tuberculous patients should be allowed to marry or to have children was discussed at the plenary session. Although there was a sharp diversity of opinion about preventing such marriages by law, it was generally agreed that persons suffering from tuberculosis in an advanced state should not marry and that the birth of children to a tuberculous woman, under certain conditions, should be prevented. Dr J. G. Hislop of Western Australia, who had led the discussion from the medical aspect, said that it seemed that a dogmatic answer could not be given to the question but that each case should be dealt with on its merits. The main factors, so far as the female was concerned, were, first, the length of time that arrest of the disease had been known, and, second, the responsibilities and duties that the marriage would bring to her. When tuberculous activity was present but the infiltration was not gross, he would include both sexes and state that financial circumstances might sanction a marriage that, in other circumstances, one would view unfavorably. Dr Hislop was in general opposed to marriage, but he considered that when radiologic and clinical tests had shown freedom from activity for two years it could be allowed. In making a decision on this point, he was swayed by the intelligence of the couple and their ability to see the reason for advice given them and to carry out that advice. Thus the question, Should the tuberculous patient marry? must be answered by a No, except when the possibilities of arrest of the disease are considerable. With regard to the question of childbearing in a tuberculous woman, it was considered that every woman with an active lesion should be advised not to have a child. It would be a potential tuberculosis patient and might be infected by the mother in her last few months of life. Dealing with the public health aspect of tuberculosis and marriage, Dr F. S. Hone of South Australia said that however successful impersonal and general administration might be in other departments of the campaign against tuberculosis, when doctors dealt with the marriage problems of the tuberculous they had to deal with practical problems affecting two individuals and their relatives and dependents. Legislation can be passed regarding the necessity for production of health certificates before marriage, but how far does that get us? The most successful campaign would

be that waged under the closest cooperation between medical practitioners and administrative officers who came into intimate contact with individuals and their practical problems. It was evident that if marriage was to be forbidden in every case of tuberculous infection a large proportion of the population would be shut out. Every patient must be dealt with as an individual case and the fullest consideration be given to all aspects of the patient's life. When there was clinical evidence of active disease with tubercle bacilli present in the sputum in individuals seen before marriage, they would be unanimous in forbidding marriage until the individual had ceased to be infective, and in most cases until three years later.

Dr T. G. Wilson of South Australia gave a paper on the obstetric aspect. One of the most animated discussions of the congress followed, with fifteen speakers taking part. Some considered that doctors should try to retain a hopeful outlook for a young engaged couple and not face them with a "catastrophic no," while others considered that persons definitely tuberculous should refrain from marriage and from having children.

Dr B. Hunt of Perth said that there was such a marked diversity of opinion among members that he would like a definite ruling from the meeting as to whether tuberculous patients should marry. The indisputable fact, he said, was that marriage was likely to lead to an increase of tuberculosis in the country, and it would be reasonable for the meeting to lay down a broad principle that it was opposed to marriage of a person in an advanced state of tuberculosis.

Marriages

DORAN THERMAN RUE, Orlando, Fla., to Miss Mildred Chambers of Chicago, June 28, in Deming, N. M.

DANIEL MINER ROGERS, New Britain, Conn., to Miss Clarinda Rosemary Moser of Rocky Hill, August 2.

BENJAMIN STALKER READ, Atlanta, Ga., to Miss Ethel Drake Houghton of Worcester, Mass., in June.

WADE HAMPTON ST. CLAIR JR. to Mrs. Mary Archer Ryland, both of Bluefield, W. Va., September 2.

VINCENT J. SIVINON, New York, to Miss Gertrude Mary Fowler of Tappan, N. Y., August 14.

HENRY VINCENT DAVIS, Chesapeake City, Md., to Miss Eloise Howard of North East, October 7.

MARTIN H. WENDROS, Philadelphia, to Miss Florence C. Siris of Camden, N. J., October 3.

CHARLES C. ENGLEHART, Harrisburg, Pa., to Miss Mary Downey of Portage, Wis., July 14.

JAMES H. GRAMMER, Fort Worth, Texas, to Miss Margaret Neil Parker of Bryan, August 26.

JOHN T. HECKER, Cedar Rapids, Iowa, to Miss Grace L. A. Darling of Moline Ill., June 12.

HORACE KENT KIBBIE to Miss Mildred Elinor Danforth, both of Fort Worth, Texas, July 28.

WILLIAM HAYS WINDLEY, Belhaven, N. C., to Miss Etta C. Carter at Washington, July 30.

IRA EDGAR FREYMAN to Miss Bertha Batt Bush, both of Weatherly, Pa., September 28.

ARTHUR EDWIN COOPER, Logan, Kan., to Miss Lillian Mary Fitch of Minneapolis, May 15.

DAVID JOSEPH GRAUBARD to Miss Florence Pearl, both of New York, August 10.

MARLIN W. HELFRICK, Belleville, Pa., to Miss Darlis Camp of Danville, June 26.

RALPH J. LOW to Miss Dorothea V. Montgomery, both of New York, recently.

HOWARD O. DEATON to Miss Lois White, both of Fort Worth, Texas, August 25.

J. ROSS SIEGEL to Miss Eve Stienberg, both of Philadelphia, August 23.

JOHN A. HOFFA, Dushore, Pa., to Miss Amy Faul of Ambler, July 14.

Deaths

Chester Tilton Stone ☉ New York, Long Island College Hospital, Brooklyn, 1915, member of an advisory board and captain of the Military Intelligence Bureau, Department of Justice, during the World War, on the staffs of the Bellevue Hospital, New York, "Bergen Pines," Ridgewood, N. J., and the Rome (N. Y.) State Hospital, at various times on the staffs of St. Bartholomew's Hospital, Woman's Hospital, St. Luke's Hospital, Post Graduate Hospital and the New York Hospital, New York, St. Lawrence State School, Ogdensburg, Long Island College Hospital, Greenpoint Hospital and Wyckoff Heights Hospital, Brooklyn, author of "Dangerous Age in Men", at one time an associate editor of the *American Journal of Physical Therapy*, aged 50, died, August 27, in St. Luke's Hospital, of peritonitis, following perforation of the small intestine.

William Frederic Andrew George Rienhoff Sr. ☉ Baltimore, Julius-Maximilians-Universität Medizinische Fakultät Würzburg, Bavaria, Germany, 1883, member of the Southern Surgical Association, Society of Clinical Surgery and the American Association for Thoracic Surgery, fellow of the American College of Surgeons, past president of the Missouri State Medical Association and the Greene County (Mo.) Medical Society served during the World War, author of "Principles and Fables of Cancer Research in Regard to Etiology and Nature", aged 79, died, August 29, at the Johns Hopkins Hospital, of heart disease.

Frederick Edwards Dilley, Chefoo, Shantung, China, Western Reserve University Medical Department, Cleveland, 1903, an Associate Fellow of the American Medical Association, fellow of the American College of Surgeons, for many years a medical missionary, superintendent of the Temple Hill Hospital, was a commissioner of the Red Cross for Western Siberia during the World War, formerly on the faculty of the Peiping Union Medical College, Peiping, China, at one time superintendent of the Peiping Hospital, aged 61, died, August 9, in Cleveland, of carcinoma of the stomach.

William Hamilton Long, Louisville, Ky., Kentucky University Medical Department, Louisville, 1903, member of the Kentucky State Medical Association, clinical professor of anesthesiology, University of Louisville School of Medicine, member of the Associated Anesthetists of the United States and Canada, past president and secretary of the Jefferson County Medical Society, on the staffs of the Louisville City Hospital, Children's Free Hospital and St. Anthony's Hospital, aged 57, was found dead, August 8, of an overdose of chloroform, self-administered.

William Melville Robertson, Warren, Pa., Trinity Medical College, Toronto, Ont., Canada, 1892, member of the House of Delegates of the American Medical Association in 1916, member of the Medical Society of the State of Pennsylvania, fellow of the American College of Surgeons, aged 74, formerly on the staffs of the Warren State Hospital and the Warren General Hospital, where he died, August 19, of peritonitis due to acute gangrenous appendicitis.

David Hendricks Bergey ☉ Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1884, director of research in biology at the National Drug Company since 1932, formerly professor of hygiene and bacteriology at his alma mater, member and in 1915 president of the Society of American Bacteriologists, served during the World War, author of 'Bergey's Manual of Determinative Bacteriology', aged 76, died, September 5, of nephritis.

Otto Sutter ☉ St. Louis, Beaumont Hospital Medical College, St. Louis, 1892, formerly clinical professor of abdominal surgery, National University of Arts and Sciences Medical Department professor of gynecology and surgery, Beaumont Medical College, and on the faculty of the College of Physicians and Surgeons of St. Louis, at one time superintendent of the City Hospital, aged 73, died, August 1, of cerebral hemorrhage.

Rudolph Johannes Kremer, Chicago, Philipps Universität Medizinische Fakultät, Marburg, Prussia, Germany, 1923, assistant professor of pathology, University of Illinois College of Medicine, served with the German Army during the World War, aged 40, director of the pathological laboratory of the Augustana Hospital, where he died, August 14, of mitral stenosis, rheumatic heart disease and pulmonary thrombosis.

Thomas Alexander Kenyon, New York, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1895, member of the Medical Society of New Jersey, served during the World War, on the staff of the

North Hudson Hospital, Weehawken, aged 66, died, August 2, in the Fitkin Memorial Hospital, Asbury Park, N J, of a broken neck

John William Kauffman, Reading, Pa, Jefferson Medical College of Philadelphia, 1896, also a pharmacist, member of the Medical Society of the State of Pennsylvania, fellow of the American College of Surgeons, aged 64, for many years chief of obstetrics at Reading Hospital, where he died, August 4, of cerebral arteriosclerosis

Sigo Ehrlich, Bainbridge, Ga, Vanderbilt University School of Medicine, Nashville, Tenn, 1915, also a pharmacist, on the staff of the Bainbridge Hospital, served during the World War, aged 49, died, August 23, in the John D Archbold Memorial Hospital, Thomasville, of carcinoma of the rectum

Harold Austin Miller, Alameda, Calif, Cooper Medical College, San Francisco, 1903, past president of the city board of health, for many years a member and president of the free library, aged 61, on the staff of the Alameda Sanatorium, where he died, August 13, of peritonitis following ruptured appendix

Richard Bruce Pozer, Eriksdale, Manit, Canada, University of Manitoba Faculty of Medicine, Winnipeg, 1923, member of the Associated Anesthetists of the United States and Canada, served during the World War, aged 43, died, August 28, near Duluth, Minn, as the result of an automobile accident

Charles Porter Sylvester, Boston, University of Vermont College of Medicine, Burlington, 1899, for many years a member and formerly chairman of the Massachusetts State Board of Registration in Medicine, aged 59, died, August 6, at Rye Beach, N H, of cardiovascular valvular disease and uremia

Jacob Stacey John, Bloomsburg, Pa, Jefferson Medical College of Philadelphia, 1896, past president of the Columbia County Medical Society, fellow of the American College of Surgeons, president and chief surgeon of staff, Bloomsburg Hospital, aged 64, died, August 11, of angina pectoris

Jesse Thomas McCartney, Barnesville, Ohio Medical College of Ohio, Cincinnati, 1903, member of the Ohio State Medical Association, served during the World War, medical superintendent of the Barnesville General Hospital, aged 64, died, August 9, of cirrhosis of the liver

Hans Moritz Lichtenstein, Winona, Minn, Eberhard-Karls Universität Medizinische Fakultät, Tübingen, Württemberg, Germany, 1890, member of the Minnesota State Medical Association, aged 70, died, August 6, in the Colonial Hospital, Rochester, of coronary thrombosis

Leon Leopold Meyer, Memphis, Tenn, Bellevue Hospital Medical College, New York, 1897, formerly assistant professor of surgery, University of Tennessee College of Medicine, served during the World War, aged 64, died, August 5, in the Methodist Hospital, of pneumonia

Theodore Charles Erb, Boston, Harvard University Medical School, Boston, 1895, member of the Massachusetts Medical Society, for many years school physician, formerly instructor in obstetrics at Tufts College Medical School, aged 66, died, August 3 of heart disease

Robert Coulter Walker, Santa Fe, N M, University of Cincinnati College of Medicine, 1924, at one time assistant professor of bacteriology at his alma mater, served during the World War, aged 43, died, August 12, of pulmonary and laryngeal tuberculosis

William Allen Stoker, Centralia, Ill, Medical College of Ohio, Cincinnati, 1885, formerly managing officer of the Kankakee State Hospital, Kankakee, Ill, and formerly superintendent of the Anna (Ill) State Hospital, aged 73, died, August 22, of cerebral hemorrhage

Carl Herbert Meissner, Oregon City, Ore, Rush Medical College, Chicago, 1902, member of the Oregon State Medical Society, for many years a member of the school board, aged 57, died, August 21, in St Vincent's Hospital, Portland, of coronary thrombosis

Louis Martucci, Newark, N J, Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1916, member of the Medical Society of New Jersey, served during the World War, aged 46, died, August 13, of acute nephritis and acute appendicitis

Guy Hart Moates, Tarentum, Pa, University of Nebraska College of Medicine, Omaha, 1923, member of the Medical Society of the State of Pennsylvania, aged 41, died August 1 near Fort Hovle, Md, of burns received in an airplane accident

Rexford Jennings Morrell, Elmira, N Y, University of Buffalo School of Medicine, 1927, on the staffs of the Arnot-Ogden Memorial Hospital and St Joseph's Hospital, aged 32, was drowned in Lake Keuka August 4, when his boat capsized

Frederic Crounse, Altamont, N Y, Albany (N Y) Medical College, 1890, member of the Medical Society of the State of New York, served during the World War, aged 68, died, August 9, of cerebral hemorrhage and arteriosclerosis

Edward Frederick Law, Fairbury, Ill, Rush Medical College, Chicago, 1903, past president of the Livingston County Medical Society, president of the township high school board of education, aged 63, died, August 5, of angina pectoris

Ralph Henry Dunning, Syracuse, N Y, Johns Hopkins University School of Medicine, Baltimore, 1911, served during the World War, for many years village health officer of Eastwood, aged 52, died, August 8, of coronary thrombosis

Joseph Raymond Pugh, Hammond, Ind, Northwestern University Medical School, Chicago, 1920, on the staff of St Margaret's Hospital, aged 43, died, August 16, as the result of a streptococcal infection of the throat

Herbert Le Roy Walker, Rock Island, Ill, Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1904, on the staff of St Anthony's Hospital, aged 56, died, August 11, of coronary thrombosis

William Henry Weston, New York, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1878, aged 87, died, July 31, of carcinoma of the rectum, in the Good Samaritan Hospital

Paul LeRoy, St Jean, Que, Canada, Laval University Faculty of Medicine, Quebec, 1922, member of the Associated Anesthetists of the United States and Canada, aged 38, died, August 10, of heart disease

Joseph Suley Wheeler, Santa Cruz, Calif, L R C S, and L R C P, Edinburgh, Scotland, 1891, member of the California Medical Association, aged 81, died, July 22, of myocardial insufficiency

Philip Tullius Johnson, Erie, Pa, Homeopathic Hospital College, Cleveland, 1892, member of the Medical Society of the State of Pennsylvania, aged 77, died, August 3, of cerebral hemorrhage

Frank Smith Post, Portland, Ore, Western Pennsylvania Medical College, Pittsburgh, 1899, member of the Oregon State Medical Society, aged 65, died, July 12, of carcinoma of the bladder

Cicero Frank Griffin, Suffolk, Va, College of Physicians and Surgeons, Baltimore, 1893, member of the Medical Society of Virginia, aged 68, died suddenly, August 4, of coronary thrombosis

William Franklin Race, Omaha, University of the City of New York Medical Department, New York, 1884, aged 79, died, July 16, in the Douglas County Hospital, of barbitol poisoning

William Hannum, Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1895, aged 66, died, August 2, in Bristol, of cerebral hemorrhage and arteriosclerosis

Hugh J Mulheron, Detroit, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1897, aged 64, died, July 27, at Rotterdam, Holland, while touring Europe

Henry Charles L Kloepper, St Louis, St Louis University School of Medicine, 1907, member of the Missouri State Medical Association, aged 56, died, August 6, of heart disease

Hermann Ernst Schaef, London, Ont, Canada, Western University Faculty of Medicine, London, 1905, member of the Radiological Society of North America, aged 55, died, July 14

Richard D Talbott, Fort Worth, Texas, Memphis (Tenn) Hospital Medical College, 1884, member of the State Medical Association of Texas, aged 76, died, August 4

Andrew Jerome Harrington, Toronto, Ont, Canada, Victoria University Medical Department, Coburg, Ont, 1889, M R C S, England, 1890, aged 76, died, August 5

John Grant Lyman, New York, New York Homeopathic Medical College and Hospital, New York, 1891, aged 72, died, July 12, of arteriosclerosis and cerebral hemorrhage

John H Sowers, South Whitley, Ind, Cincinnati College of Medicine and Surgery, 1889, aged 71, died, August 8, of paralysis agitans and chronic myocarditis

Charles Alexander Durham, Fairfield, St Catharines, Ont, Canada, Trinity Medical College, Toronto, 1890, aged 73, died, July 4

George M Seigenthaler, Bethany, Mo, American Medical College, St Louis, 1877, aged 84, died, August 1, of chronic myocarditis

Arthur Teninga, Chicago, Rush Medical College, Chicago, 1919, aged 42, died suddenly, August 6, of coronary thrombosis

Bureau of Investigation

VITAL-EX

Death Notice of Vital-ex Testimonial Giver Appears on Same Day as Advertisement Boosting Nostrum

Recently the Louisville Times published a notice of death of a Mr Robert Edward Walker, aged 68. On the same day appeared Mr Walker's testimonial extolling the virtues of the 'patent medicine' known as 'Vital-ex.' The news item relating to Mr Walker's demise and the Vital-ex advertising heralding Mr Walker's remarkable experience with this medicine are reproduced.

Vital-ex, apparently the same nostrum once advertised without the hyphen has been exploited chiefly by the testimonial type of newspaper advertisement for "weak, run-down, tired out, ailing, nervous, rheumatic people." Several years ago the

LOUISVILLE MAN HAD UPSET STOMACH AND CONSTIPATION FOR TWENTY YEARS; PRAISES VITAL-EX

Had Awful Stomach Sourness A Hot Sour, Water Brash Would Rise Up In My Throat, Bowels Required Strong Laxative—Now Mr Walker, 3721 Center St, Louisville, Cannot Praise This Medicine Too Highly!

You too can get relief from after meal distress stomach pains belching sluggish liver jumpy nerves sleeplessness and constipation.

Just visit the VITAL-EX MAN who is now introducing and explaining this new mixture of fine pure ingredients at Taylor's Drug Store Third and Jefferson Sts.

Now read the true statement of Mr Robert Walker 3721 Center St. who is well known throughout this section.

"I am a man of 72" said Mr Walker and since I was 52 years old I have suffered with an upset stomach. For years it seemed like eternal torment.

MR. WALKER.

VITAL EX has worked like magic on my stomach and bowels—that awful hot sourness is gone—my heart doesn't jump—I am relieved of gas and pains in my stomach. I do not need soda anymore. Sleep better than I have in years and wake up in the morning ready to start the day with a smile and plenty of energy and strength. VITAL-EX regulated my bowels, too and I don't have to keep taking laxatives like I did.

I just can't thank VITAL-EX enough and I say to all who suffer as I did get VITAL-EX and you will get relief.

A special representative known as the VITAL-EX Man is now at Taylor's Drug Store 3d and Jefferson Sts. introducing and explaining this remarkable combination to crowds of people daily. —(Advertisement)

Man Expires As He Boosts Remedy In Ad

One of the most unusual quirk occurred with the death of heart disease Wednesday of Robert Edward Walker 68 of 3721 Center St. on the same day a testimonial advertisement from him praising the benefits of a proprietary medicine appeared on page 1 section 1 of The Times.

One line in Mr Walker's testimonial said that since taking three bottles of the medicine he felt like a new man. Death of Mr Walker a retired carpenter and former city night watchman was hastened by shock and worry over his son and daughter in law who were injured in an automobile collision Monday night. Surviving Wife Mrs. Anna son Cary Lee.

Walgreen Company was plugging Vitalex under such banner headings as "Health Leaders Acclaim Vital-ex Discovery." The health leaders in this instance were Dr W T Welch, Dr H J Perkins and Nurse Arline Hall. The advertisement was accompanied by a large photograph showing presumably, Welch, Perkins and Nurse Hall grouped around a desk, gazing at a bottle of Vital-ex. When the Bureau of Investigation looked up the 'health leaders' it was found that Dr W T Welch held a diploma from the Hahnemann Medical College and Hospital Chicago, dated 1914. No one by the name of H J Perkins was found as the holder of the degree of Doctor of Medicine. Nurse Hall was not identified.

In May 1937 the Buffalo Better Business Bureau Inc., sent to the Bureau of Investigation an advertisement of Vital ex

which, they stated, had appeared in the Buffalo Times, May 19, 1937. In this Vital-ex advertisement a photograph of an elderly, spectacled individual appeared over the title Dr. Johnson, Buffalo, N. Y. The Buffalo Better Business Bureau reported "Our immediate problem was to find out who Dr. John Jackson is. Our city directory and telephone directory listed no practicing physician of this name. We called John J. Jackson, a chiropractor. On May 19, 1937, we called on John J. Jackson and found him to be a young and very pleasant colored chiropractor—not the venerable person whose picture appears in the Vital-ex advertisement. The photograph of Dr. John Jackson was the heading 'Dr. Johnson Says.' The consumer not trained in the 'patent medicine' advertising might conceivably assume that Dr. John Jackson was a distinguished and well known physician of Buffalo and that it was he who was responsible for the statements of Dr. Johnson. Johnson might easily be Dr. John Jackson. Since the Vital-ex label carries the caption 'Dr. Johnson's Vital-ex,' it is quite understandable that Dr. Johnson would state 'Never in my whole experience have I run across such a remarkable product as Vital-ex.'

The United States Food and Drug Administration however did not share Dr. Johnson's views that Vital-ex was a remarkable product—assuming that the current Vital-ex is the old Vitalex. In October 1931 the government declared Vitalex to be adulterated and misbranded and worthless as a source of vitamin D. The article was alleged to be misbranded for the reason that the statement on the carton, 'To which are added Vitamins D' was false and misleading, since the article contained no vitamin D. According to the government report, analysis of a sample of Vitalex showed that it consisted of caffeine, salicylic acid, benzene and small proportions of plant drugs including licorice, wild cherry and a laxative drug, strychnine, valeric acid and volatile oil, alcohol and water.

It is not extraordinary that Mr Walker should consider himself improved or that he should write a testimonial. But the testimonial and the death notice in the same issue are a satirical comment on the value of such testimonials.

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE The abstracts that follow are given in the briefest possible form (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the composition, (4) the type of nostrum, (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product.]

Pierl Stringent—Alpha Laboratory Inc. Chicago. Composition Essentially common salt sodium alum boric acid and a small proportion of picric acid. For vaginal disorders. Not anti-epileptic or germicidal as represented. Fraudulent therapeutic claims.—[N J 24626 April 1936]

Penor's (Dr) Regulator Pills—Dr George D. Stoner trading as Dr G. D. Stoner Co. Lakeland Fla. Composition Essentially a ferrous sulfate volatile oils including pennyroyal and a trace of unidentified alkaloid coated with sugar and colored pink. For menstrual disorders and other female troubles. Fraudulent therapeutic claims.—[N J 24627 April 1936]

Lambert's (J O) Syrup—Dr J O Lambert Ltd. Troy N. Y. Composition Essentially chloroform creosote volatile oils including eucalyptus menthol and wintergreen with small amounts of epsom salt a little sugar and water. For coughs catarrh bronchitis asthma etc. Fraudulent therapeutic claims.—[N J 24631 April 1936]

Pheno Cosan—Whitney Payne Corp. New York. Composition Essentially a mercury compound a salicylate and tar in an emulsion of fatty acids and water. For chronic eczema wounds sores etc. Fraudulent therapeutic claims.—[A J 24632 April 1936]

Va Jel—Alpha Laboratory Inc. Chicago. Composition 12 per cent gum tragacanth lactic acid glycerin traces of eucalyptus line sulfate and oil of citronella and water. Fraudulently represented as a cure for leukorrhea venereal diseases etc.—[A J 24631 April 1936]

Va J Aseptic—Alpha Laboratory Inc. Chicago. Composition Essentially common salt (67.8 per cent) baking soda (24.14 per cent) and small proportions of thymol and menthol. For leukorrhea infections etc. Fraudulent representation.—[A J 24637 April 1936]

Correspondence

NEW DRUG CONTROL LEGISLATION NEEDED

To the Editor—The recent tragic deaths from chlor sulfamide have brought quite vividly to the public's attention the extreme danger of taking medicine without thorough experimental and clinical trial. The time seems ripe now for us to see that legislation is enacted and rigidly enforced against

1 Any drug or medicine sold to the public not acceptable to the Council on Pharmacy and Chemistry of the American Medical Association

2 Druggists and drug clerks prescribing "over the counter" Any doctor or any one else prescribing drugs without knowledge of their property, actions, uses and contraindications should be condemned most heartily

Why drugs in the U S Pharmacopoeia, the National Formulary and New and Nonofficial Remedies are not adequate is quite a mystery to me. One can surely find the desired product in one of these three sources if one would only take the necessary time to look it up

L L BEALL, M D, Cleveland, Miss

THE RECORD OF THE PATIENT'S HISTORY

To the Editor—A well taken history is complementary to a well done physical examination. A skilled historian needs no special history form and, indeed, may rise above the handicap of a grossly inadequate one. The student, however, is much influenced in his career by the form with which he is first familiarized. It is interesting to observe with what tenacity the student in his subsequent professional career sticks to habits ingrained as an undergraduate. I wish to suggest a minor revision of the standard medical history form.

The standard history form is broadly divided into History of the Present Illness, Personal Medical History, and Family History. The divisions H P I and P M H may be justified on the basis of expediency but lead to the development of a narrow perspective with reference to the development of disease processes. I believe that the history of the present illness and the personal medical history ought to be incorporated under a single heading. Beginning chronologically with infancy, then developing the medical history year by year, and episode by episode, and leading up to current aspects of the case, leads to a concept of the case, and a picture of development of disease processes as a continuous whole. The classification History of the Present Illness is largely inspired by the psychology of a layman patient who dates the onset of his illness from his first incapacity, disability or symptom, even though the physician does carry the history of the present illness back somewhat more remotely.

The scientific ideal in history taking should, however, be an attempt to trace an illness back to its hereditary or remote environmental origins. For the present, it must suffice to trace an illness back to childhood or infancy. In an acutely developing hemiplegia where does the present illness begin? With the onset of aberrations of consciousness? With the onset of paralysis? This is rather loose medical thinking. The present illness began many years previously with occasional breathlessness on effort, occasional headache, transitory paresthesias. Limiting the history of the present illness to a recent dramatic episode of a long drawn out illness represents layman psychology. An adolescent has hepatomegaly, ascites and a positive blood Wassermann reaction. Did not his present illness begin with the generalized rash in infancy, followed by bone lesions and iritis? Did not the patient with mitral stenosis begin his present illness with repeated upper respiratory infections and

anemia antedating by many years his first recent hemoptysis? In the adult with pulmonary tuberculosis did not his present illness begin in early childhood with recurrent febrile episodes, repeated respiratory episodes? In a case of acute cardiac infarction, the present illness did not develop recently with dramatic suddenness but rather with the slight dyspnea of many years ago, an occasional cough, occasional visual disturbances, and nocturia of some years past.

One might ask wherein lies any significant difference between the standard form subdivided into History of the Present Illness and Personal Medical History and a revised form embracing both of these under a single heading, Medical History (M H). Let me repeat again that in the case of the skilled historian this may be of no importance but for purposes of student training of considerable importance. A form helps establish a point of view and serves as a channel to direct the historian properly. That some change in the present form is necessary is evidenced by the following:

1 A review of a large number of hospital charts will show that the space allotted to the personal medical history averages about 5 to 10 per cent of the total history space.

2 The personal medical history usually consists of scant memoranda of the yes-no type under diseases and symptoms in contrast to the carefully written chronologically continuous narrative employed in the history of the present illness. Even granting that the greater length allotted the history of the present illness is for the development of symptoms which the patient demands be relieved, the scantiness of space and paucity of details in the average personal medical history a priori indicate an undue overemphasis on the history of the present illness. Facts essential to a clear conception of the evolution of a disease are slighted. If used subsequently for purposes of analysis, charts lack data indispensable in attempting to establish disease or symptom associations and etiologies.

The history pattern used by the psychiatrist could well serve as a model for a medical history. To the psychiatrist the apparently recent onset of mental symptoms is never anything but an episode in the development of psychologic processes whose roots run back to childhood and infancy. The psychiatrist thinks in terms of lifelong influences and a gradual unfolding of a personality. The identical point of view is applicable to somatic disease and should be imitated.

NATHANIEL HURWITZ, M D, Philadelphia

RESUSCITATION

To the Editor—Why is it that clinicians who nowadays generally recognize—at least in words—the dependence of the healing art on the fundamental sciences nevertheless often in practice neglect the plain teaching of those sciences and follow the suggestions of commercial advertisements and sales agents?

A case in point is the treatment of babies who, because of asphyxia or narcosis, fail to breathe spontaneously at birth. Anatomy teaches that the lungs of such babies are atelectatic, that is, collapsed. Physiology teaches that for respiration to be developed the lungs must first be at least partially inflated. Yet time after time for the past twenty-five years, under various names, a certain type of apparatus for artificial respiration that obviously violates the principles of both these sciences has been more or less successfully foisted on clinicians.

Such apparatus is designed and expressly advocated not only to blow air into the lungs, which, if effective and not too forcible would do good but also to suck air out of the lungs, and thus to keep the lungs collapsed or again render them atelectatic.

The first and most celebrated of these appliances was the pulmotor. Back in the years 1912 and 1913 the National Electric Light Association in order to obtain advice regarding electric shock, and the United States Bureau of Mines for

advice on resuscitation from asphyxiation by mine gases, requested the American Medical Association to recommend a commission for investigation of the subject of resuscitation. The commission that was appointed included Dr W B Cannon, chairman, Dr S J Meltzer, Dr Joseph Erlanger, Dr G W Crile and me. After extensive investigation of all known methods of artificial respiration, this commission made certain positive recommendations which have now for many years been generally adopted, but it expressly disapproved the pulmotor. And, as the disapproval was directed to the principle involved, it applies not only to the pulmotor but equally to all apparatus of its type, of which the latest is the E & J resuscitator, advocated in a recent article in THE JOURNAL (Martinez, D B. The Mechanical Resuscitation of the New-Born. A Report of 500 Cases, THE JOURNAL, Aug 14, 1937, p 489).

The main argument offered for all such appliances is a demonstration of their capacity alternately to inflate a rubber bag (simulating the lungs) and then to suck it flat. The reversal from blowing to sucking is automatically induced by the resistance of the bag when full or empty. Of this feature of such apparatus the commission reported:

Inflation and deflation of a bag is deceptive because the bag, unlike the air passages of the body, offers no resistance till full. As soon as the inspiratory blast meets an obstacle in the air passages however it is automatically cut off and turned into expiration and thus frequently no efficient inspirations are performed. The second harmful factor brought out by these experiments is the performance of expiration by suction. In normal respiration expiration is accomplished by a power that does not suck but drives out the air by the elasticity of the distended or compressed tissues aided sometimes by muscular contraction. [After detailing its various lines of investigation in laboratory and clinic the commission report said:] Upon the basis of these observations the conclusion was reached that the automatic mechanism of the pulmotor although an ingenious technical contrivance instead of assuring artificial respiration may interfere greatly with its efficiency, because the mechanism is liable to cut off inspiration prematurely.

In this verdict two other committees of investigation, one in 1918, the other in 1921, unanimously concurred (Report of the Commission on Resuscitation from Electric Shock, New York, National Electric Light Association, 1913. Report of the Committee on Resuscitation from Mine Gases, Technical Paper 77, U S Bureau of Mines, Washington, D C, 1914. Work of the Commission on Electric Shock, editorial, THE JOURNAL, Nov 1, 1913, p 1637. Proceedings and Resolutions of the Third Resuscitation Commission, *Science* 48 563 [Dec 6] 1918. Drinker, C K, and Redfield, A C. *J Indust Hyg* 6 109 [Aug] 1923. Final Report of the Commission on Resuscitation from Carbon Monoxide Asphyxia, *ibid* 6 125 [Aug] 1923). Evidence, which I have more recently obtained from obstetricians who have tested the E & J resuscitator on asphyxial or deeply narcotized babies, is to the effect that it frequently merely "clicks" from inspiration to expiration and back to inspiration in rapid succession without producing any movement of air in or out of the lungs. In some cases also autopsy has shown definite injury to the lungs.

General experience with the Drinker apparatus affords evidence which bears on this topic. It indicates that mechanical artificial respiration should be confined to a succession of inspirations and should not include forced expirations. When the body is enclosed in the Drinker apparatus, negative pressure induces inspiration in essentially the same way as does positive pressure over the face with apparatus of the pulmotor type. In the Drinker apparatus forced expirations by positive pressure are now generally omitted. And as negative pressure over the face acts similarly, it also should be omitted. Artificial respiration confined to inspirations, either with the Drinker or the pulmotor type of apparatus, if not too forcible, can do no harm but forced expiration with either type of apparatus can. If then, the principal objection to the pulmotor, the E & J resuscitator and similar devices is to be removed, negative pressure should be omitted. It should be added that, among the cases in which the E & J resuscitator has been used the latest to come to my knowledge is one in

which a child had to be removed for a time from a Drinker apparatus. During this time the E & J resuscitator was substituted but the child died.

What then should be recommended for the resuscitation of the new-born? First and foremost, obstetricians should be more conservative than is often the case now in administering narcotics shortly before delivery (Bundesen, H A, Dalton O A, Fishbein, W I, and Hamm, G E. Mortality of the New-Born in Chicago During 1935, with Special Reference to the Premature, THE JOURNAL, July 25, 1936, p 270. Henderson, J H. The Chicago City Wide Plan for the Care of Premature Infants, *ibid*, Aug 8, 1936, p 400). There is ample evidence that such drugs act far more on the baby than on the mother (Henderson, Yandell. Respiratory Stimulants and Their Use, THE JOURNAL, Feb 6, 1937, p 471). Doses that merely quiet her render the baby entirely apneic. Second, the passage of a soft catheter into the trachea of an apneic and flaccid baby is so simple an operation and insufflation by the Meltzer Flap technique (Flagg, P J. The Treatment of Postnatal Asphyxia, *Ann J Obst & Gynec* 21 537 [April] 1931) is generally so effective that there is little justification for any other procedure.

YANDELL HENDERSON, PH D, New Haven, Conn.

RECURRENT LARYNGEAL NERVE

To the Editor—I have always felt that in any formal terminology the primary purpose to be achieved was the clear and concise exchange of information and ideas. Unfortunately, anatomists have not always considered clinical convenience in setting up word lists, and clinicians, especially in America, seem to abhor formality in names.

At the present time the BNA, which is just being adopted in some clinical circles, is being either discarded or markedly altered in anatomic circles. The current suggested changes seem to follow nationalistic manners of thought, if not actual political boundary lines.

To me the statement in the editorial in THE JOURNAL, July 14, "Injury to the recurrent laryngeal nerve was recorded in 8.2 per cent of the cases. In no instance was it bilateral or permanent is perfectly clear and anatomically accurate. I am a little surprised that Dr John F Quinlan of San Francisco finds grounds for objection (Injury to the Recurrent Laryngeal Nerve, THE JOURNAL, September 4, p 809). Considering the matter of terminology, I quote for convenience from the comparative tabulation prepared by the committee of the American Association of Anatomists. The list was to be used by the association members in considering proposed changes. The numbers preceding the names are cross reference notations from the American committee's list. BNA refers to the Basle Nomenclature, BR to the present approved British list, and NK to the list of the Nomenklatur-Kommission. Nerve branches not concerned with the present discussion have been omitted.

AAA		BNA	
171	21	N	recurrens
171	25	N	laryngeus inferior
171	26		Ramus anterior
171	27		Ramus posterior
BR			
171	21	N	laryngeus recurrens
171	25		Rami pharyngei
171	26		Rami laryngei
NK			
171	21	N	recurrens
171	25	N	laryngeus caudalis
171	26		Ramus ventralis
171	27		Ramus dorsalis

Since the designations "right" and "left" are omitted in structures so named are normally bilateral. The right recurrent laryngeal nerve (to follow the language of the editorial and the BR) "recurs" about the right subclavian artery,

its point of origin. It is closely related or may be in contact with the innominate artery and, I would presume, could be sufficiently distributed by intrathoracic changes to cause vocal paralysis. Occasionally, owing to peculiarities in the embryonic transformations of the aortic arches, the right nerve does not recur but is distributed directly from the vagus nerve shortly below the superior laryngeal nerve. This condition occurs once in 500 cases in an English series, Adachi found one case in 516 Japanese cadavers. The incidence is much higher in the Negro. I see from one to three cases a year in our cadaveric material here in Philadelphia.

I regret that we cannot, for practical purposes, attain a common anatomic terminology, but this difficulty even with the present multiplicity of commissions is not as great as it has been in some epochs of anatomy.

OSCAR V. BATSON, M.D., Philadelphia
Professor of Anatomy, University of Pennsylvania Graduate School of Medicine

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

METRAZOL TREATMENT OF INSANITY

To the Editor—1. What is the nature of the metrazol treatment of mental disease? 2. Over how long a period does it extend? 3. What is the immediate effect on the patient? 4. What is the anticipated result of such a treatment? 5. What risk to the patient's health, mental or physical, is involved? 6. What degree of permanence can be expected from any resultant improvement?

M.D., Illinois

ANSWER—1. The metrazol treatment can be classed as a shock treatment and was first developed by Meduna of Budapest, who calls it a "convulsive therapy." The convulsions are induced by rapid intravenous injections of metrazol, which has a pharmacologic action similar to camphor and usually produces typical epileptiform seizures with doses of from 3 to 10 cc of the 10 per cent solution.

2. According to Meduna, the treatment is given twice a week and usually consists of from ten to twenty convulsions.

3. The immediate effect does not seem to differ from that produced by the ordinary epileptic seizure and is usually followed by transitory confusion and somnolence, after which marked improvement of the patient's mental status may supervene.

4. Meduna's reports compare favorably with those for the insulin shock treatment; Friedman of Buffalo has recently reported an improvement in thirty of forty cases treated by this method.

5. Sustained periods of confusion may occasionally follow the seizure, but there is usually no permanent deleterious effect on the patient's mental status. The most frequent complications are those attendant on ordinary seizures, namely, luxations, fractures or physical traumas and less frequently cardiovascular accidents.

6. The treatment is too new to give adequate information on the frequency of relapse.

ULTRAVIOLET RAYS FOR DESTROYING RINGWORM IN SHOES

To the Editor—It has been suggested that the official applicator of my cold quartz generator might serve in the sterilizing of the shoes of my patients suffering from the various fungous infections of the feet. Would this procedure be of any value in the prevention of recurrence?

M.D. Michigan

ANSWER—It is true that ultraviolet rays of the proper wavelengths are efficient in destroying bacteria and fungi. As to whether they would prevent recurrences of eczematoid ringworm of the feet from organisms remaining in the shoes is doubtful.

The applicator would have to be held long enough in every recess of the shoe and one would have to make certain that there is no fold anywhere in the lining or leather in order to expose the entire inside surface of the shoe. Even were

that possible, it is still doubtful that all the fungi would be killed. Scrapings have been made from the inside of shoes and it has been found that cultures of fungi can be made from some of the relatively deeper parts. It is well known, of course, that ultraviolet rays will penetrate only within a fraction of a millimeter of such materials as leather, and for this reason the organisms not on the surface of the inside of the shoe would still remain viable to start a fresh infection.

It would be more practical to use chemicals to accomplish the same end. The formaldehyde fumigation method is perhaps the most simple and yet efficient method for this purpose.

COLD PRESSOR TEST FOR STABILITY OF VASOMOTOR SYSTEM

To the Editor—The cold pressor test of Hines and Brown mentioned near the top of the second column, page 933, in *THE JOURNAL*, March 20, sounds most interesting. Can you give a brief description of the test?

GEORGE M. SHEAHAN, M.D., Quincy, Mass.

ANSWER—The cold pressor test, devised by Hines and Brown, was first reported in the *Proceedings of the Staff Meetings of the Mayo Clinic* 7:332 (June 8) 1932. Additional significant reports are

Hines E. A., Jr. and Brown G. E. *Ann Int Med* 7:209 (Aug) 1933.
Am Heart J 11:1 (Jan) 1937.
Briggs J. F. and Oertling Harry. *Minnesota Med* 16:481 (July) 1933.

The technic of the cold pressor test is simple and the procedure is applicable to office use. The subject is permitted to rest in a recumbent position while several determinations of the arterial tension are made until a basal level is reached. The hand of the arm opposite to that on which the sphygmomanometer cuff is applied is then placed in ice water (4°C) well up the wrist. The arterial tension is determined at the end of thirty seconds and again at sixty seconds. The hand is then removed from the ice water and readings of the arterial tension are made every minute until the tension returns to its previous basal level. The maximal tension is usually observed thirty seconds after the exposure to cold, although it may be occasionally delayed. Some subjects find the immersion of the hand in ice water painful, but there is no relationship between such sensitivity and the response of the arterial tension. It is the degree of rise in the diastolic tension which is most significant although the changes in the systolic tension should be likewise observed. The two significant values are (1) the rise in the diastolic tension or "response" and (2) the level of the maximum diastolic tension observed.

The reaction of the arterial tension under these conditions is remarkably constant in any single individual, variation on repeated studies averages about 10 per cent. The types of response observed fall into five groups. 1. In normal persons the average rise of the diastolic tension is about 10 mm of mercury. The return to previous basal levels is prompt. 2. In hypertensive individuals with little or no arteriolar sclerosis the rise is from 25 to 40 mm. As these patients have higher than normal basal levels, the maximum diastolic readings are often very high. Despite this, no untoward effects of the test have been reported. The fall in the tension to previous levels is often somewhat delayed. 3. Hypertensive patients with varying degrees of arteriolar sclerosis give varying responses, from 10 to 30 mm rise is usual. 4. Arteriosclerotic patients without hypertensive arterial disease respond as do normal persons. 5. Hyperreactive individuals with normal basal levels of blood pressure react with an exaggerated rise in both the systolic and diastolic tensions. In these patients the diastolic usually rises from 20 to 30 mm. It is this last group that is perhaps the most interesting. These patients should be considered as being in a "prehypertensive state" or as having "potential hypertension." The transition from such potential hypertension to hypertensive arterial disease has been observed a number of times. The present concept of hypertensive arterial disease lays great stress on the intrinsic constitutional vulnerability of the patient as an important factor in the etiology. The cold pressor test reveals inherent instability of the vasomotor mechanism and thus indicates, often prior to the development of persistent hypertonia, the vulnerability of the individual. Ayman (*Arch Int Med* 53:792 [May] 1934) and others have shown that this hyperreactive type of response is much more frequent in children from families in which hypertension exists in one or both parents than in others. Dieckmann and Michel (*Arch Int Med* 55:420 [March] 1935) demonstrated those patients with pre-existent renal and/or vascular injury gave exaggerated reactions early in pregnancy and that such reactions were a warning of the likelihood of later intoxication. These tests were made early in pregnancy, when the urinary examination gave normal results. The reactions in preeclamptic patients

were variable. In chronic nephritis in pregnancy the test caused violent upheavals of the arterial tension.

Many further clinical studies are necessary before all the significant implications of this test are thoroughly understood. It is especially necessary to follow for many years the younger hyperreactive patients so that the development of hypertensive arterial disease can be better studied in the early stages. In summary it may be concluded that this procedure offers much useful clinical information regarding the equilibratory mechanism of the circulation and that its application for the detection of prehypertensive individuals is a most fertile field.

ADDISON'S DISEASE

To the Editor—In Queries and Minor Notes in THE JOURNAL August 21 appeared an inquiry by M. D., Michigan concerning a test for and the treatment of Addison's disease. The answer is defective in two respects. First the response of the patient to a salt poor diet is mentioned as a diagnostic test. It is said that failure of this test does not exclude Addison's disease. The point should have been made that, as Wilder and his co-workers have stated (*Proc Staff Meet Mayo Clin* 11:281 [April 29] 1936) it is important to regulate the potassium content of the diet if withdrawal of salt is used as a diagnostic test for Addison's disease. With a low intake of potassium (16 Gm or less) symptoms may be slow in developing or even indefinitely postponed while the restriction of sodium chloride may provoke serious relapse if the intake of potassium is high (4 Gm or more). Second the discussion of treatment fails even to mention the low potassium diet used first by the Mayo Clinic. Reports by Wilder and his associates, Webber (*Maine M J* 27:235 [Dec] 1936) and by me (to be published in the *Southern Medical Journal*) indicate that a low potassium diet plus administration of sodium salts may suffice to maintain patients in good condition.

ROBERT J. HOAGLAND, M.D., Fort Sam Houston,
San Antonio, Texas

COMMENT—With regard to the control of the potassium content of the diet in patients with Addison's disease, the point of the communication is well taken as far as it applies to the treatment of severe cases of Addison's disease. The work of Wilder and his associates points clearly in this direction, although their clinical studies were complicated by various controllable and uncontrollable factors, some of which are mentioned in their articles (R. M. Wilder and others, *Proc Staff Meet, Mayo Clin* 11:273 [April 29] 1936, *Arch Int Med* 59:367 [March] 1937). In the first of these articles, it is said that "attention will have to be paid to the potassium content of the diet prescribed for patients who have severe Addison's disease." The reply in THE JOURNAL assumed that the patient would be kept on a normal diet (including the usual potassium content) during the salt withdrawal test. No one knows what effect excessive administration of potassium may have on the outcome of this test in very mild or early cases of Addison's disease. It is obvious, however, that if the fear of provoking a serious relapse during the restriction of sodium chloride should lead physicians to reduce the potassium intake during the test, the diagnostic value of the test would be considerably diminished for that very reason.

In the discussion of the treatment, reference to the low potassium diet was omitted because the question referred to the treatment for "an early case of Addison's disease." Even a superficial familiarity with the labor of preparing and the unpleasantness of ingesting a diet low in potassium should make one hesitate to prescribe such a diet except when it is seriously indicated, namely, in severe cases of Addison's disease which fail to respond adequately to the usual therapeutic measures.

MASTURBATION IN WOMEN

To the Editor—What is the treatment of masturbation in a woman who is a graduate nurse? M.D., New York.

ANSWER—The treatment is different for the unmarried than for the married woman. It is especially difficult in a trained nurse, who has access to all sorts of erotic literature and who is often in intimate contact with young male patients, not to mention young male hospital interns.

In all women, whether married or not, it is important to remove all local genital irritations, such as intertriginous and eczematous conditions about the genitals. It is immaterial whether the local condition is the cause or consequence of the masturbation. Even if not the cause, it serves to keep up the habit and to attract the attention of the patient to her genitals, thus delaying a cure. Gymnastic exercises which might bring into play thigh friction, such as sliding down the banisters, sliding down a slippery pole, or bicycle and horseback riding, should be avoided. Operations on the genitals are of no value unless some distinct condition aside from the habit is present. Erotic literature and especially erotic movies and plays should be forbidden. The maxim in treatment is to replace the habit. Any outdoor hobby, such as swimming, golfing or tennis, is of value. One must not talk in vague hints but put the issue

squarely before the patient and try to develop her will power and self control. Hard work, no matter of what nature, is of great value. Any inclination to be alone should be discouraged. These directions apply to single and to married women alike.

For single women it is absolutely essential to avoid statements as "nothing will cure your condition except marriage" or "the habit will leave you when you get married" and the like. In the first place the statement is obviously false, and in the second place the young girl may take the hint and indulge in illicit coitus. It is more important to emphasize especially to a trained nurse who knows something about the anatomy and physiology of the female genitals, that masturbation develops those areas in the brain which are connected with the external genitals at the expense of those areas connected with the vagina. As a consequence, the ordinary act of coitus with its vaginal friction will not give as much pleasure or response as masturbation and so, if she marries later, the result might be frigidity. This explanation to a trained nurse may act as a deterrent to the habit. Long marriage engagements should be discouraged, for they keep up in both parties a state of sexual erethism which encourages masturbation. Especially harmful is spooning, "necking parties" and similar experiences. For a brief period the internal administration of bromides will help to tide over a severe urge. Tea, coffee and alcoholics must be avoided absolutely.

In married women the condition is often started or kept up by the practice of withdrawal in the husband. Here the husband interrupts the act of coitus before he reaches his own orgasm and almost necessarily before the wife has had hers. As a result the wife is left in an excited, unsatisfied condition and often either she or her husband titillates her clitoris to bring on the orgasm. This practice must be absolutely interdicted and the husband must be instructed about this as well as the wife and furthermore he should be instructed in the art of normal coitus. The avoidance of tea, coffee and alcoholics as well as the occasional use of bromides is the same as in single girls.

SIGNIFICANCE OF WASSERMANN REACTION

To the Editor—The statement on page 609 of THE JOURNAL August 21 that the Wassermann reaction is absolutely diagnostic of syphilis with the exception of yaws cannot go unchallenged. Should this statement be taken literally it will undoubtedly condemn many innocent people as being affected with syphilis. If you will refer to an article published by me on the diagnosis of syphilis in the April 1926 issue of *Southwestern Medicine* you will find the following: "It is not perfect. Yaws a tropical disease caused by a spirochete will give a positive test fever will at times give a positive test and when repeated after the fever is gone will yield a negative reaction. Constipation may give a positive test jaundice at times gives confusing reactions. Tuberculosis may give a positive reaction although it will usually give a stronger reaction with tuberculous antigen. This quotation referred to the Wassermann test and the article went into detail as to the efficiency and reliability of the Wassermann test at that time, and I have had no occasion to alter my opinion of it since." H. M. PURCELL, M.D., Phoenix, Ariz.

ANSWER—After consultation with several clinical and laboratory authorities on the diagnosis of syphilis, the following answer appears to represent the majority opinion of those best qualified to discuss this subject. Three types of false positive reactions must be distinguished: technical false positive reactions—those due to some error in the performance of the test which occur in every laboratory, no matter what the test used and which are not confirmed on testing a second specimen; biologic false positive reactions, caused by the presence in serum or spinal fluid of actual reagin in the absence of syphilitic infection and in which both the Wassermann and the flocculation test are persistently positive; and, finally, what may be termed the anomalous false positive reaction, in which only the Wassermann reaction is positive, the flocculation reaction is persistently negative, and the patient presents no clinical evidence of syphilis. Technical false positive reactions constitute the majority, and hence the reliability of the laboratory test is the first factor that enters into the interpretation. The next most important factor is the sensitivity of the test, which depends not only on the type of test used but in some instances on a deliberately obtained increase in case of reactivity.

The general opinion is that there are only five diseases other than syphilis which may produce persistently false positive serologic tests in a high percentage, namely, yaws, leprosy, malaria, trypanosomiasis and relapsing fever. Positive tests are sometimes obtained in tuberculosis, malignant disease, fever, jaundice, pneumonia, Hodgkin's disease, malignant endocarditis, infectious mononucleosis and other conditions, but the interpretation may fail to take into account the possibility of technical false positives or the fact that the patient actually has a symptomless latent syphilis. Furthermore, the majority of the false positives are of the doubtful variety. It is

clear that the Wassermann and flocculation tests for syphilis are not absolutely diagnostic of syphilis, although with the exception of the five diseases previously mentioned they can usually be so considered when allowance is made for the technical factors mentioned

UNRESOLVED? PNEUMONIA

To the Editor—A woman aged 51 always in good health until February 1 came down with grip followed by bronchopneumonia which behaved typically for two or three weeks. Since that time there have been occasional days when her temperature remains normal but usually it is between 99 and 101 F. Her sputum shows pneumococci and streptococci but no tubercle bacilli. X-ray examination of the chest shows a fairly large area of unresolved pneumonia in the lower left portion with possibly a little fluid below the axilla but none posteriorly, a smaller area in the lower right part of the chest is not resolved. A needle failed to locate fluid. There is a persistent racking cough with profuse thin yellowish sputum loaded with pus cells. Nothing that I have been able to do has changed the situation in the past month. Kindly let me know what one can do to hasten resolution in such a condition for nobody seems to think that there is much except general care that affords any hope of relief, and the patient as well as her physician is getting terribly tired of the whole situation. ROBERT W SHEARMAN M.D. Brooklyn

ANSWER—For the complete diagnosis of this case it is essential to determine the nature of what is termed "unresolved pneumonia." It is necessary to exclude an infected atelectasis or suppuration in a pulmonary lobule due to retention from productive inflammation in its bronchiolar wall. The possibility of a localized empyema draining through a bronchus should be excluded. Information concerning the bacterial etiology of the bronchopneumonia is lacking and may still be supplied by cultural study of the pus. If the "unresolved?" pneumonia is due to continued infection it may be relieved, depending on the cause, either by autogenous vaccines or by roentgen therapy.

Careful studies should be conducted to determine the anatomic nature of the lesion. This may require either roentgenography with iodized oil or bronchoscopy.

HISTAMINE TEST AND GASTRIC SECRETION

To the Editor—In THE JOURNAL April 24 in an article entitled Gastric Carcinoma and Peptic Ulcer Dr Crinston Holman gives a technique of stomach analysis by the use of histamine hydrochloride hypodermically. He did not give the interpretation of the readings of this test. Can this method be successfully used instead of the test meal analysis of the gastric contents in neurosis and peptic ulcers? If so what is normal and what is abnormal? An attempt has been made to use it at St Mary's Hospital but the readings have been quite high compared to those of the test meal analysis. Please give a statement as to its use in all cases of gastric analysis and also how to interpret the readings especially in normal persons.

JAMES A HILL M.D. Jefferson City Mo

ANSWER—This question is answered best by referring to the article by A L Bloomfield and W S Pollard entitled "The Diagnostic Value of Studies of Gastric Secretion" (THE JOURNAL, May 4, 1929, p 1508) and the review of the literature on histamine as a stimulus in gastric secretion by L M Gompertz and M G Vorhaus (*J Lab & Clin Med* 11 14 [Oct] 1925). In brief, the method can be used successfully instead of the other types of test meals in the analysis of the gastric contents in neurosis and peptic ulcers. The question as to what is "normal" may be answered in part by the following quotation from Bloomfield and Pollard: "In general, it may be said that most normal persons have a maximum ten minute secretory volume of not under 15 cc and not over 35 cc and a total acidity of not under 90 and not over 125. The highest acidity we have ever encountered was 150, the greatest ten minute secretory volume was 60 cc. The entire range as regards both acid and volume may, however, be encountered in persons without other evidence of gastric disease."

All these statements are important. In the first place, as Dr A J Carlson pointed out a number of years ago all known pathologic variations of gastric secretion are depressions. The normal stomach may secrete as highly acid gastric juice and apparently as large a quantity of gastric juice as is seen in disease. Disease depresses the secretion if it affects it at all. The second important point is that all variations from high grade secretion to complete (histamine) anacidity are encountered frequently in persons without other evidence of gastric or other disease.

The greatest advantage of the histamine test is that a histamine proved anacidity is almost surely true anacidity,

for histamine is the most potent known stimulus for gastric secretion. The most important thing to know clinically with regard to gastric secretion is whether or not the stomach is able to secrete acid. If it is able to secrete acid, the patient does not have pernicious anemia (Sturgis, C C, Isaacs, Raphael, Goldhamer, S M, Bethell, F H, and Farrar, G E. Blood. A Review of the Recent Literature, *Arch Int Med* 55 1001 [June] 1935) or posterolateral sclerosis of the spinal cord (Oliver, T H, and Wilkinson, J F. Achlorhydria, *Quart J Med* 2 431 [July] 1933), if the stomach is unable to secrete acid, the patient does not have a benign peptic ulcer (Palmer, W L. The Mechanism of Pain in Gastric and Duodenal Ulcers. I. Achlorhydria, *Arch Int Med* 38 603 [Nov.] 1926), Fundamental Difficulties in the Treatment of Peptic Ulcer (THE JOURNAL, Nov 18, 1933, p 1604).

It is self evident that the old classification of "normal free acidity" in terms of clinical units, as from 20 to 40, of "hyper-acidity" as above 40 and of "hypo-acidity" as below 20, is incorrect and should be discarded. The important and perhaps the only significant point is whether or not the stomach is able to secrete acid.

REINFECTION OR RELAPSE OF SYPHILIS

To the Editor—A patient contracted syphilis in January 1925 and three months after the disappearance of the chancre started treatment at which time the blood Wassermann reaction was 4 plus. Between January 1925 and 1928 the patient had thirty six doses of neoarsphenamine 106 mercury injections and twenty four doses of bismuth subsalicylate in oil plus indeterminate amounts of iodine. In 1928 after these varied kinds of intermittent treatment the reaction of the patient's blood was constantly negative and the spinal fluid examination was negative once. He remained well until January 1937 at which time he started treatment for a hard indurated irregular ulcer of the scrotum the size of a quarter (24 mm) with inguinal adenopathy. The stained slides from the lesion showed a few spirochetes. The blood Wassermann and Kahn reactions were both 4 plus. Spinal fluid and darkfield examinations were omitted. The lesion healed quickly with neoarsphenamine. 1 Was the lesion a recurrence of the original infection or a reinfection? 2 What procedures should have been done to determine whether this is a reinfection or a recurrence? 3 Are there any authenticated cases of reinfection with syphilis and if not is there any definite proof of immunity to the disease? 4 If this diagnosis cannot be definitely determined that is recurrence or a reinfection what would be the best plan of treatment? Should the patient be treated as having a seropositive primary lesion (provided cardiovascular and neurosyphilis are ruled out) or should he be treated as having a later type of lesion? 5 Should neoarsphenamine be used?

H J BECK M.D. Lamar Colo

ANSWER—The evidence presented suggests that the patient had a reinfection. The period of twelve years between the "first" and the "second" infection favors a reinfection. It is rare to see a patient with a relapse and a positive darkfield examination twelve years after the chancre.

Stokes lists seventeen indisputable, eight probable and five possible criteria of reinfection. The case under discussion complies with seven of the eight points for the "probable" criteria of reinfection, namely, (1) indisputable first infection, (2) negative clinical and serologic examinations for more than one year, (3) second chancre at a different site from that of the original one, (4) no signs of activity of the first chancre, (5) positive darkfield examination on the second chancre, (6) an adjacent bubo and (7) a positive blood Wassermann reaction. The eighth criterion, that is, the appearance of "secondaries" twenty days or more after the appearance of the chancre, was not noted in the description.

There are no procedures which can now be done to prove that this was a reinfection. However, there are several factors which if elicited would make the argument for reinfection more potent. It is essential to locate and determine whether the partner, the suspected source of the second infection, has evidence of acute syphilis. Note whether the incubation period from the time of exposure to the appearance of the chancre was within the normal range. A patient suspected of having a reinfection may be allowed to go untreated to note whether he develops secondaries following the second chancre, this, of course, is not possible in the case under discussion at this time. The appearance of a bubo and a positive darkfield examination for *Spirochaeta pallida* on aspiration of the bubo are further evidence that the patient has a reinfection.

There are some authentic cases of reinfection, although most of the suspected cases are in reality examples of a recurrence or relapse. Definite proof of immunity to the disease is lacking although there is presumptive evidence that some persons do have a definite resistance to syphilis, which minimizes the severity of the course of the infection or produces spontaneous cure.

As far as treatment is concerned it actually makes little difference whether this is a case of reinfection or of recurrence, because the patient should be treated intensively as having

early syphilis. The use of the continuous system of treatment, employing arsphenamine or neoarsphenamine and a bismuth compound, is recommended for such a patient. He should receive a minimum of thirty injections of arsphenamine and fifty of a bismuth compound.

Neoarsphenamine is slightly more toxic and has a slightly lower therapeutic index than arsphenamine. Accordingly, it should be given in somewhat smaller doses but with more injections to the course. Eight injections of neoarsphenamine should constitute a course, with the dose ranging from 0.3 to 0.7 Gm., depending on the age, sex, weight and general status of the patient.

OCCLUSION OF DIGITAL ARTERIES

To the Editor—A printer aged 46, has been troubled for the past four years with a gradually increasing uncomfortable sensation of numbness and tingling and coldness in the finger tips. The sensation is blunted so that he is unable to operate the keyboard of a linotype, which requires an accurate sense of pressure. He has also noted a tired feeling in the calves of the legs without pain, after walking. General physical examination is rather negative. The past history is that of one of usual normal health. There is no diabetes. The blood Wassermann reaction is negative. The blood pressure examination reveals a systolic blood pressure of 100/110, with a diastolic pressure of 80. Blood count reveals 5,000,000 red blood cells and 6,000 white blood cells. Blood smear reveals nothing abnormal. X-ray examination revealed several ulcerated teeth and one devitalized tooth without ulceration. An injection intramuscularly of 0.0125 cc of mecbolyl resulted in vasodilatation of the skin all over the body and of the arms and hands down to the proximal phalanges leaving the distal portions of both hands in the same color, which appeared blanched in comparison. I could not appreciate any change in temperature nor did the patient feel any warmer in the tips of the fingers after the injection as he did in other parts of the body. I am thinking of treatment with alternating suction and pressure. What about the possibility of an occupational cause? What about an allergic cause? What other lines of treatment should be considered? What about the practicability of a ganglionectomy?

M D Cleveland

ANSWER—The data presented suggest an organic arterial occlusion of the digital arteries and perhaps of the arteries of the lower extremities, although nothing has been said about the absence or diminution of the pulses of the foot and popliteal space. Sudden drop in skin temperature at certain levels or a difference of temperature between symmetrical areas of the lower extremities should be looked for. Focal infection originating in the teeth, tonsils and prostate must be eradicated. A twenty-four hour specimen of urine can be examined for lead and arsenic. In interpreting the results, the upper limits of normal lead excretion in Cleveland must be known, as this varies in different communities. Should the lead excretion be high, a cautious deleading with ammonium chloride and a change in occupation are advisable. Smoking, if practiced, should be absolutely prohibited. Sufficient water intake up to ten to twelve glasses of water with an addition of 10 Gm (150 grains) of sodium chloride in the form of tablets helps to increase the water content of the blood. If there is no evidence of arteriosclerosis by palpation or x-ray examination of the pedal arteries, a course of intravenous injections of triple typhoid vaccine may be started. The doses may be kept so low that chills and high temperatures are avoided. A course consists of from ten to twelve treatments.

If after such a conservative regimen there is no definite improvement, a sympathectomy can be considered. Whether or not this operation is going to be successful depends chiefly on the proper selection of the case, which requires considerable experience and should be left to the judgment of a surgeon familiar with this type of work. He will test the capacity of the vascular bed to dilate with physical or chemical vasodilators and will perform a complete sympathetic denervation by pre-ganglionic section.

Results of suction and pressure treatment in this type of case have not been definite.

VARICOCELE

To the Editor—What is the possibility and incidence of acute varicocele arising suddenly without preexisting signs or symptoms such as pain, red streaks and swelling? Kindly include etiologic factors, types and locations of acute varicoceles.

BERNARD L. ROBBINS M D Miami Beach Fla

ANSWER—Varicocele is a dilatation, elongation and tortuosity of the spermatic veins. It is a common condition in young men and is much more frequent on the left side than on the right. In all probability this is due to the fact that the left spermatic vein enters the left renal vein at a right angle, making venous return more difficult than on the right. Varicocele may be symptomless for a long time unless attention is directed toward the lesion. When that happens, a peculiar hypochondriac state develops and mental symptoms of varying degree may follow. Of course when the varicocele becomes inordinately large a distressing sense of weight, pressure in the loin,

in the groin and in the back is perfectly understandable. Red streaks and swelling, as mentioned, are not encountered in cases of varicocele unless a phlebitis of the spermatic veins is present, which is rare.

The actual cause of varicocele is the incompetence of the valve at the orifice of the left spermatic vein followed by reflux of blood from the vena cava. This is brought about by increased intra-abdominal pressure transmitted along the unvalved spermatic vein. There may be one or several interior trunks and one posterior trunk, which anastomose freely with one another and constitute the pampiniform plexus. These trunks often have valves, but if the valve at the renal vein is incompetent they gradually become incompetent too.

There are two possible answers to the question raised by the inquiry: either there has existed a fully developed varicocele, which was asymptomatic and to which sudden attention has been called by an injury, or a sudden rise in venous pressure, following an unusual strain, has actually opened up a venous segment in the pampiniform plexus and has thus aggravated a preexisting, congenital defect. As no clinical data are supplied in this hypothetical case, any further statement would be of speculative nature.

CRAVING FOR CELERY

To the Editor—I am writing with regard to a patient who has a craving for celery. She can go about three days without eating it and then gets very nervous and feels that she must have celery. If she goes three or four days without eating any celery she must eat a whole bunch to be relieved of her symptoms. After eating the celery she is very calm. She says she could eat celery every day. She has tried various other vegetables and greens and has also taken medicine, but none have taken the place of celery. Her mother and grandmother were both morphine addicts. However, her mother acquired the habit after the patient was born. The habit was acquired by giving morphine for pain. Her mother was cured of the habit. I should like to know whether anything can be suggested that would be of benefit or give me light on this subject.

C J LARSEN, M D Stoneham, Mass

ANSWER—A patient with this particular craving has never been encountered by the writer, although of course other examples of unusual craving have been seen. Frequently they are of considerable significance. For instance, before the discovery of Whipple, Minot and Murphy regarding the significance of liver in pernicious anemia, physicians occasionally encountered patients with pernicious anemia who had a craving for liver. A craving for salt in patients with Addison's disease is frequently encountered, in which the administration of large amounts of salt has been found to be beneficial, and a craving for foods that supply vitamins, encountered in men who have been subsisting on a vitamin poor diet. Numerous other examples might be cited. There is no obvious substance that celery could provide that might otherwise be lacking. It would seem wise to respect the craving and allow as much celery to this patient as she would care to eat. Large amounts of celery would probably not do her any harm, and to withhold the food under the circumstances might be harmful.

ASCITES

To the Editor—Please give me the quickest and best treatment for ascites in a person 60 years of age. How can one determine whether it is of portal or nephritic origin? Will intravenous mercurial preparations do any good in an ascites of portal origin?

A R WANAMAKER M D Hamburg Iowa

ANSWER—Ascites is due to so many different conditions that one can give but a short summary of some of the more important causes in this reply. By the same token it is impossible to give any adequate suggestions as to therapy, because no data are submitted to furnish a clue as to the cause of the ascites in this patient. Portal obstruction is not a simple entity. Any condition interfering with the flow of blood in the portal circulation, of intrahepatic origin, as in the cirrhosis, or of extrahepatic origin from anything occluding the portal vein, as a thrombosis, or compressing it, as tumors or enlarged lymph nodes, may lead to the development of ascites. Chronic peritoneal irritation from chronic inflammation and neoplasms may also cause ascites. Congestive heart failure with engorgement and cirrhotic changes in the liver may be accompanied by ascites. This condition, however, may be primary or it may be a complication frequently a terminal event in one or another form of chronic nephritis or nephrosclerosis in the course of chronic hypertension.

Ascites is a rare symptom of acute nephritis and its consideration evidently does not enter here. The diagnosis of nephritis requires not alone urinalyses but a study of the blood chemistry and renal function. Relief of the ascites may be obtained by paracentesis of the abdomen under sterile precautions the needle entering in the midline about 3 or 4 cm. above the symphysis. A local anesthetic as 0.5 or 1 per cent

procaine hydrochloride, may be used with advantage. This procedure may be repeated with the return of ascites. The medical means of relief of ascites are, first, if the condition is cardiac, an attempt to improve cardiac action. The mercurial diuretics, of which salyrgan or mercupurin is an example, may be given intravenously or deep intramuscularly, in doses beginning with half an ampule, subsequently increased to a full ampule every few days. At the same time the patient should get 0.65 Gm of ammonium chloride three times daily. The response may be immediate, in a few hours, or it may not occur for several hours and continue for from two to even three days. Albuminuria is no contraindication to its use. The use of a mercurial diuretic may be continued indefinitely. Recently suppositories have been introduced which in some cases seem to produce considerable diuresis.

TREATMENT OF PRURITUS ANI

To the Editor—Have there been any recent developments in treatment of severe chronic pruritus ani? What are considered the best solutions for injection?

FRANK C. GREEN, M.D., Chillicothe, Ill.

ANSWER—In cases of severe chronic pruritus ani it is important to see that the rectum is normal, polyps, fissures, hemorrhoids and large skin tags should be removed. An area of dermatitis can be injected through multiple punctures with a fine hypodermic needle, punctures being half an inch apart and injecting below the dermis about 2 minims (0.12 cc) of absolute alcohol in each puncture. The area injected is then covered with zinc oxide paste and instructions are given the patient to avoid rubbing with bath towels, sponges, toilet paper and other irritating or traumatizing agents. The alcohol causes a numbness of the region for about three months and with suitable hygiene of the skin most patients are either cured or at least receive definite relief.

SULFANILAMIDE SOLUTIONS

To the Editor—Enclosed please find one of the clippings now on the front page of the daily press relative to deaths from a solution of sulfanilamide. I have on my desk a three ounce sample of solution of sulfanilamide with citra lactate dispensed by Donley Evans and Company, St. Louis. Do you have any information relative to this product?

M.D., St. Louis

ANSWER—None of the products of the Donley-Evans Company have been accepted by the Council on Pharmacy and Chemistry. The Council has not accepted any solution of sulfanilamide. There is no evidence available to indicate that any preparation of sulfanilamide is stable in solution form. In order for the Council to recognize a solution of sulfanilamide, the product must be stable and, at the same time, the solvent must be nontoxic in the doses given. Possibly a satisfactory solvent has been developed. However, there is no evidence to indicate that this is the case. Until such time as a product of this type is devised, physicians will do well to prescribe only accepted brands in powder and tablet form.

TOXICITY OF *di*-CHLORO *di*-FLUOROMETHANE (FREON)

To the Editor—Can you furnish me with information regarding the toxicity of Freon, the gas commonly used in air conditioning? I should like to know the symptoms of toxicity and the relative concentration of the gas necessary to produce symptoms. Are the effects of this gas cumulative?

ALBERT H. MANN, M.D., Texarkana, Ark., Texas

ANSWER—Freon is stated to be *di*-chloro-*di*-fluoromethane, K-12. This refrigerant is discussed in a publication based on hearings before the fire department of the city of New York and embracing materials prepared by "Freon" manufacturers on one side and E. T. Williams and John Kenlon on the other. This report is controversial but does contain an extensive bibliography. *Di*-chloro *di*-fluoromethane, although compounded from highly toxic substances, is in itself substantially nontoxic. It is substantially free from irritant properties and apparently acts only as an asphyxiant. When it replaces oxygen in the atmosphere, it leads to asphyxiation solely by displacing oxygen. Apparently a high concentration, such as 20 per cent of the total atmosphere, may be required in order to bring about noteworthy injury under ordinary circumstances.

This compound may readily decompose, particularly when affected by heat, leading to the presence of new compounds of much higher toxicity. It has been stated that "freon" on decomposition yields hydrogen chloride, hydrogen fluoride, chlorine and phosgene. Of these substances phosgene is perhaps the most important as a toxic agent, if in appreciable quantities in a respired atmosphere, though the toxicity of fluorine is not to be discounted. So far as known, no cumulative effects are

produced by the prolonged inhalation of this gas. However, the technical data available, based on animal experimentation, are somewhat lacking in extended observations. All in all, at this time it appears possible to rate this gas as one of the least hazardous of the substances used in mechanical refrigeration in absence of conditions (such as fire) that may lead to decomposition. The perfect refrigerant has not been discovered.

MYOSITIS OSSIFICANS

To the Editor—Please advise me whether there has been any new treatment for progressive myositis ossificans. I have a patient with it and she does not seem to respond to any treatment. M.D., Louisiana

ANSWER—No effective therapy for progressive myositis ossificans is known. Tutunjan and Kegerreis (Myositis Ossificans Progressiva, *J. Bone & Joint Surg.* 19 503 [April] 1937) have recently reviewed the literature and reported one case in detail. They have suggested the administration of beryllium carbonate, which is known to reduce the inorganic phosphorus content of the serum. Beginning with doses of 3 Gm a day and later increasing this to 6 Gm daily, they gave their patient a total of 200 Gm without noting any untoward symptoms but with no definite evidence of improvement or decalcification of either the bones or the abnormal deposits. The authors express the opinion that more favorable results might be obtained if the subjects are available prior to the full development of the osseous system and if the treatment could be carried out over a much longer period.

ANCIENT SCHOOL OF MEDICINE

To the Editor—I am seeking information about a school of physicians known as "methodists" which existed about the middle of the fifteenth century and which discarded observation and held to the pure deductions of reason and logic.

J. W. YANCA, M.D., Brenham, Texas

ANSWER—No reference has been found to any school of physicians known as "methodists" in the fifteenth century. Perhaps the Greek school which flourished in the second century A.D. is meant. References to this school are:

Lund, F. B. Greek Medicine (Clio Medica) New York, Paul B. Hoeber, Inc. 1936, p. 72 ff.
Allbutt, T. C. Greek Medicine in Rome, London, 1921, p. 192 ff.
Meyer, Stern, T. Das medizinische System der Methodiker, Jena, 1916 (Jenaer medizinisch-historische Beiträge No. 78).
Edelstein, L. Methodiker in Pauly Wissowa, Real-Encyclopädie der classischen Altertumswissenschaft, Supplementband VI, Stuttgart, 1935, cols. 358-373 (philosophical background of the school).
Sigerist, H. E. The Great Doctors, New York, Norton & Co., 1933, pp. 56-67.

SUBCUTANEOUS OR INTRAMUSCULAR INSULIN

To the Editor—Recently in two articles on the treatment of schizophrenia by insulin shock, I have read that the insulin injections should be given intramuscularly. My teaching has been that insulin should not be given intramuscularly and I find statements to the latter effect in recent textbooks. In one recent textbook is the statement that "if insulin is injected into the muscles necrosis occurs and scar tissue forms." Can you explain this apparent discrepancy?

E. J. KELLNER, M.D., Kenilworth, Ill.

ANSWER—In diabetic clinics everywhere the invariable rule, so far as we know, is to advise the subcutaneous administration of insulin as the method of choice. Hence there is probably little available information as to the local effect of present-day insulin when given intramuscularly. It must be remembered that the insulin now distributed by pharmaceutical houses is a purer preparation than that in the early days following its discovery.

It is possible that those who have had considerable experience in the treatment of schizophrenia with insulin shock may have made further observations on the point in question, but no published statement has come to our attention. It may be noted that in a recent report from one clinic in this country (*J. A. M. A.*, 109 1246 [Oct. 16] 1937) insulin for the shock treatment was given subcutaneously.

VIOSTEROL (A R P I PROCESS)

To the Editor—Will you be good enough to throw some light on the viosterol (A R P I Process) in oil which was covered in an advertisement that I read in your issue of September 18. I am not quite clear as to whether or not this viosterol is made by a new process and if so how it effects its results on the human body. Please omit name.

M.D., Illinois

ANSWER—This product was fully discussed in the report of acceptance by the Council on Pharmacy and Chemistry published in *THE JOURNAL*, October 2, page 1126. The report is based on a large mass of toxicologic, pharmacologic and clinical material submitted to the Council with the viosterol (A R P I Process).

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL October 30 page 1475

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS *Parts I and II* Examinations will be held in all centers where there is a Class A medical school and five or more candidates who wish to write the examination Feb 14 16 May 9 11 (limited to a few centers) June 20 22 and Sept 12 14 Ex Sec Mr Everett S Elwood 225 S 15th St Philadelphia

Washington July Report

Mr Dave S Cohn, secretary, Department of Licenses, reports the written examination held in Seattle, July 12-14, 1937. The examination covered 7 subjects and included 70 questions. A grade of not less than 60 per cent in any subject was required to pass. Forty-five candidates were examined, all of whom passed. Twenty-six physicians were licensed by reciprocity and 6 physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad	Per Cent
University of Arkansas School of Medicine	(1935)	68.5

Book Notices

Physical Diagnosis The Art and Technique of History Taking and Physical Examination of the Patient in Health and in Disease By Don C. Sutton M.D. Associate Professor of Medicine Northwestern University School of Medicine Chicago Cloth Price \$5 Pp 495 with 306 illustrations St Louis C V Mosby Company 1937

As a basic textbook for the academic teaching of physical diagnosis, this one has many excellent features and few faults. It is mainly practical, in parts concise, and easy to read. Illustrations are for the most part well chosen, especially the few charts and the roentgenograms. The first portion of the book is made up of an excellent section on the art of medicine and the history of physical diagnostic methods. The author is to be commended on his interesting presentation of this material. The chapter on the taking of a history is rather brief, particularly the portion dealing with gastro-intestinal diseases. Many statements in this chapter are dogmatic, yet some could not be accepted by every internist and surgeon. The section on the heart covers 150 pages and, with the introductory chapter, comprises half of the entire book. It is obvious that the author is particularly interested in cardiology. The thirteen pages dealing with cross-sectional anatomy of the heart do not seem essential in a book of this type. While the chapter seems too detailed for inclusion in so general a work, even its length does not detract from its value. The chapter dealing with examination of the thorax is well written. The illustrations are clear and well placed. The section on abdominal examination is adequate but that on neurologic investigation is rather sketchy. It is to be regretted that the author failed to stress the importance of rectal examination. It seems that it should not be performed only "when indicated" but rather that it should be considered a routine measure. On the whole, however, there are few faults in this well planned book on a difficult but fundamental subject.

Personality and the Cultural Pattern By James S. Plant M.D. Director Essex County Juvenile Clinic Cloth Price \$2.50 Pp 432 New York Commonwealth Fund London Oxford University Press 1937

Dr. Plant has had a number of years' experience doing child guidance work, in fact, he was one of the earliest child guidance experts in this country. His clinic in Essex County, N. J., is a splendid example of work that can be done, yet Dr. Plant professes to be thoroughly disappointed in the psychiatric approach although he does not say so directly. He emphasizes that the individualization of the case and the so-called case history method, looking into the dynamics of the individual, whether due to heredity or to environment, are in themselves inadequate. What one needs if one is to make an adequate study of any case is the careful analysis of, first of all, the personality as it is seen and, second the influence of cultural and sociological processes on the individual. The earliest part of this volume deals with the general thesis emphasizing that the psychiatric approach, so long as it deals only with the individual without relation to its environment, is more or less sterile. The way that this aspect has been phrased does not give it any tinge of newness, for mental hygienists have for years stressed the fact that other approaches beyond the mere interview with the patient and the reconstruction of the patient's

past life through conventional methods are necessary and that one must study the complete cultural pattern. But Plant goes beyond this. He formulates a systematized way of thinking about the whole problem. He points out, for instance, that truancy is not a single experience, that it does not arise from a single cause but that there are a number of rather vague causes which the child himself perhaps does not recognize in which the truancy has its inception. Various cultural interrelations are thoroughly worked out. He discusses certain angles of personality study which in themselves are not new but which have an enlightening and stimulating effect when studied from his point of view. The last part of the book emphasizes the picture presented today by the various sociological agencies: the family, the social agency, the church, the school, the court and industry. At these Plant looks in a rather critical light, perhaps not so much novel as thoroughly recrystallizing and clarifying. While one does not agree with many of his statements, since the book is highly theoretical and not based on the cold scientific method, which perhaps is not really applicable here, opinions on the subject are open to diversification, yet one cannot deny that the volume is stimulating. One would scarcely consider a modern mental hygienist, child guidance psychiatrist or any one else interested in the relationship of the social problem of mental health properly equipped without some acquaintance with this work.

Gastroscopy The Endoscopic Study of Gastric Pathology By Dr. Rudolf Schindler Associate Clinical Professor of Medicine University of Chicago With a preface by Dr. Walter Lincoln Palmer Associate Professor of Medicine University of Chicago Cloth Price \$7.50 Pp 343 with 185 illustrations Chicago University of Chicago Press 1937

This new volume in English should be welcomed by those members of the American profession who are interested in gastroscopy. It is not a translation of the author's earlier *Lehrbuch und Atlas der Gastroscopie*, published in 1923, but is completely new. The book contains twenty-one chapters, the first eight of which are devoted to historical, anatomic, technical and physiologic fundamentals. Chapter 10, on gastritis, is of special interest. The author maintains that 50 per cent of all patients examined are found to have gastritis, and he regards it as the commonest of all gastric lesions. His simple classification of the chronic nonspecific forms of gastritis into superficial, atrophic and hypertrophic commends itself. To this group is added postoperative gastritis. Chapters 14, 18 and 20, on the postoperative stomach, the relationship between gastroscopy and surgery and the relationship between gastroscopy and the x-rays, are of interest to the surgeon and the roentgenologist.

Schindler minimizes the danger of gastroscopy to the patient when the flexible instrument, fitted with a rubber finger tip, is used. He feels that gastroscopic examination should be a routine method of the gastro-enterologist just as cystoscopy should be a routine method of the urologist. The amount of air to be blown into the stomach is one of the most delicate problems of gastroscopic technique, in his experience, and he properly stresses the difficulties of orientation. The production of an image that corresponds more nearly in size with reality in all parts of the stomach is still an unsolved optical problem. He frankly admits that ulcers of the pylorus and duodenum cannot be seen gastroscopically and that the lesser curvature of the antrum often remains hidden from view. And yet it is at these sites that gross benign and malignant lesions, usually readily demonstrated by the competent roentgenologist, are almost exclusively situated. He lists a variety of twelve conditions in which he feels that gastroscopy is regularly indicated, including duodenal and gastric ulcer and gastric carcinoma. His justification for advising gastroscopic examination of a patient with duodenal ulcer, especially if an operation is under consideration, is that there may be an associated gastric ulcer or gastritis present. "In the differentiation of benign and malignant gastric ulcer, gastroscopy is, in my experience, second only to microscopic examination." But his description of a lesion under the caption "carcinomatous ulcer" is really that of a good sized ulcerating carcinoma.

The author's observations on gastro-intestinal hemorrhage are pertinent in large measure. He feels that this condition is an important indication for endoscopic examination, for often the x-ray examination does not reveal the cause, which may

be an actual ulcer demonstrable only by the gastroscope, or a severe hemorrhagic gastritis, hemorrhagic erosion or a benign tumor. Postoperative hemorrhages are often due to a gastritis. Such examination should be made after the bleeding has stopped. The gastroscopic appearance and differential diagnosis of all types of ulceration of the gastric mucous membrane are summarized in chapter 13. The gastroscopic determination of the exact size or depth of an ulcer is found to be difficult. Gastroscopically it is usually easy to follow exactly the process of ulcer healing, and the author has observed that the crater is often found to persist even after the niche has disappeared on x-ray examination.

Schindler states that in gastritis all parts of the stomach are affected, but all gastroscopists agree that the body is much more frequently involved than is the antrum. "The concept of a special antrum gastritis arose apparently from the fact that the specimens obtained by surgical resection consist chiefly of the antral portion of the stomach." The author feels that the most common reason for failure in gastric surgery is the development of a "terrible and incurable chronic gastritis." This does not appear to occur in well adapted and rhythmically contracting stomas. He has observed that the surgeon, as a rule, does not appreciate the importance of gastroscopy as does the internist who has seen the interior of the stomach through a gastroscope.

In the diagnosis of carcinoma or in the determination of its operability the author now takes the position that combined x-ray and gastroscopic examination is superior to the exploratory laparotomy and obviates the surgical risk and mortality inseparable from such exploration, that gastroscopy decides the question of the nature of a pyloric obstruction, whether benign or malignant, even better than does examination during the operation and thus predetermines whether a gastro-enterostomy may suffice or whether the more hazardous resection is indicated. Gastrophotography is rightly condemned with faint praise. The x-ray diagnosis of gastritis seems to be extremely untrustworthy, in Schindler's opinion. There, however, appears to be one x-ray picture almost diagnostic of the extremely severe forms of hypertrophic, nodular gastritis, the so-called granulation relief picture.

It is quite obvious that the average clinician and surgeon will not be in entire accord with all the views expressed by the author. Certainly those with a large experience in this field would challenge a number of the conclusions at which he has arrived, at the same time readily conceding his frank sincerity, his masterly skill and his enthusiasm. Nevertheless, this new volume is a classic of its kind and will be one of the greatest incentives to have gastroscopy assume its rightful place in the diagnostic armamentarium of all progressive medical clinics and hospitals in this country.

Le bacille de type bovin dans la tuberculose humaine. *Revue de la documentation actuelle*. Par le Docteur Marcel Gervois. Paper. Pp 314. Lille. Imp. L. Danel. 1937.

This book is a thorough presentation of tuberculosis in the human body produced by the bovine type of tubercle bacillus. The author has included a chapter on the avian bacillus and presents a few cases of disease in man produced by the avian type of bacillus, which have been reported from time to time. This number is so small and the data leading to the diagnosis are so incomplete as to lead one to believe that the avian type of tubercle bacillus produces clinical disease in man only with great rarity. The author has assembled the literature from various parts of the world and has compiled numerous tables. For example, from 221 articles over the past thirty-five years he has collected 17,045 bacteriologic examinations to determine the type of tubercle bacilli. He has also assembled information on 260 observations on pulmonary tuberculosis produced by the bovine type of bacillus. A great deal of emphasis is placed on the transmission of the bovine bacillus to man and the pathogenesis of the disease. Such factors as the age of the patient and the incidence of the disease among rural and city dwellers are discussed. The last section of the book is devoted to methods of prevention. Reference is made to 473 articles and it is gratifying to see in this bibliography the names of so many from the United States who have taken an important part in eradicating tuberculosis from cattle.

Visual Perception. By M. D. Vernon. M. A. Cloth. Price \$4.00. Pp 247 with 19 illustrations. Cambridge University Press, New York. Macmillan Company, 1937.

Most psychology textbooks contain a selection from the experimental work on visual perception, but no book covers the entire field in a comprehensive and detailed manner except this one by Miss Vernon. Her aim has been to make the treatment thorough but to avoid any preconceived theoretical bias in the interpretation of the facts.

The material in the book falls under four main headings. First there is an account of the phenomenal development of the perceptual process up to the final stage of meaning and the reaction tendencies. The second section deals with the relation of the perceptual content to certain of the affective states and attitudes. The third section treats of the objective structure of the perceptual field. In the fourth section there is a description of the genetic development in childhood of the perceptual content. Finally she turns to the classification of individual differences.

Miss Vernon admits that her account of the different features of the perceptual process and its relation to meaning and to various secondary sensory and imaginal processes may resemble the old atomistic approach. However, she had been cautious in her acceptance of the reality of these constituents, pointing out that the preconceived ideas and theoretical bias both of experimenter and of subjects may have vitiated the results to an unknown degree.

She shows a preference for the functional approach, as opposed to the "structuralist" position pointing out how the latter involves a certain rigidity in the analysis and classification of the types of awareness.

In her treatment of the work of the gestalt school of psychology she has avoided any exhaustive criticism of *gestalt theory* and has limited her account to some of the experimental results which seem empirically valuable.

The final sections of the book delve into the newer and debatable field of individual differences. It is pointed out that the gestalt psychologist has been neglectful in this field, to which his theories only partially apply. On the other hand, Miss Vernon is no champion of the strict typological classification. She believes that any classification of types (whether perceptual, imaginal, synesthetic types or temperament and personality types) should be thought of as a "mere shorthand expression" for types of differences, which will serve our purposes if rightly used.

One of the most interesting and valuable sections in the book is this last part, dealing as it does with types of reactions of individuals to life situations. Miss Vernon has shown an ability to correlate the work of different investigators, noting points of correspondence, ignoring minor differences, so as to introduce a semblance of clarity into a confused and contradictory field. She has criticized the Rorschach classification of personality types as being purely empirical, without rational basis (in a theoretical sense) and as having a low statistical reliability. But she claims that as a quantitative view of the whole personality the scheme has undoubted value. It is more detailed, comprehensive and flexible than other classifications. The introversion and extroversion classification resembles Jung's introvert-extravert typology. Also it bears a similarity to Kretschmer's cycloid-schizoid and Jaensch's integrate-disintegrate. Since it contains as an essential element a classification according to color and form responses, it is in agreement with Oeser's color and form dominant classification. Miss Vernon admits that the apperception type is of most interest to her, since it summarizes and goes beyond the previous work on the subjective-objective, synthetic-analytic and active-passive perceptual types.

The physician and more especially the psychiatrist may find the section on synesthetic types useful as an aid in the interpretation of various abnormal phenomena. The concept of synesthesia is a familiar one, since it is well known that certain people have associations between different types of images. That is, the stimulus presented to one sense channel seems to call up imagery in another mode as readily as that of its own. Although temperamental instability and strong emotionalism are

not necessarily present, still the phenomena may be associated with adolescence, emotional stress, nervous fatigue, illness, and so on.

In the section on imaginal types, reference to the eidetic image is made, and this type of imagery is clearly differentiated from the primary memory image and the after-image. A conclusion is drawn that the fixed type of eideticism is more common among younger children, when it is a normal phenomenon. But the labile type of eideticism increases in the period of puberty and may be associated with emotional disorders.

Miss Vernon states her general conclusion thus: "It is characteristic of these schemata [types of directing tendency, perceptual patterns, and so on] that they provide an immediate and automatic connection between the experiencing individual and the supposed nature of his environment. Thus the observer is normally unaware of the stages in the development of the percept, of the differentiation of form, the assimilation of past experience, the understanding of meaning, he experiences the percept not as a phenomenon arising within his own consciousness but as something really existing in the external environment."

Thus the schemata not only provide facilities for the most rapid and efficient development of the percept but also for its reference to and correlation with the essential aspects of the external environment.

"So the naive individual believes that his percepts are completely determined by the external stimulus conditions and are referable in their entirety to some real object or system of objects which exist outside himself. But we have endeavored to show that the phenomenal percept is determined entirely by the established functional schemata—for instance, feelings of familiarity, attitudes, affective tendencies, and so on, and indirectly we become aware of them by studying the nature of the perceptual content. But of their actual structure, the method by which they are established and the manner in which their individual impulsive tendencies are coordinated, we know nothing."

We have attempted to dig the ground, to clear away the debris, and perhaps prepare the foundations, as yet we cannot foretell the nature of the edifice to be built thereon."

Tweedy's Practical Obstetrics. Revised and largely rewritten by Bethel Solomons MD FRCP FRCOG Gynaecologist Dr Steerens Hospital Dublin and Ninian McIntire Falkner MD ScD FRCP FRCPI Visiting Gynaecologist Royal City of Dublin Hospital. Seventh edition. Cloth Price \$8.75. Pp 773 with 295 illustrations. New York & London Oxford University Press 1937.

The present edition contains many changes. Some recommendations made in the last edition have been revoked. For example the authors no longer recommend the cervical cesarean section for placenta praevia but now prefer the classic operation. They do not look with as much favor on twilight sleep as they formerly did. Solomons is now definitely opposed to the use of chloroform during labor. He believes that ether is the method of choice in cases of toxemia. Many obstetricians, especially American ones, are of the firm belief that the anesthetic of choice in all cases of toxemia is local anesthesia. The authors continue to advocate gastric lavage and colon flushings, but these measures have almost entirely been given up in this country. Submammary "transfusion" (infusion) is described and illustrated but it is best to avoid injecting large quantities of fluids under the breasts not only because of the immediate pain that results but also because of the discomfort that often arises when the flow of milk is established. The inner surface of the thighs is a better place for injecting fluids subcutaneously. The authors advocate episiotomy only in cases of rigid perineum. The Solomons modification of the De Lee head stethoscope is identical with that proposed by Hillis when the head stethoscope was first devised. Most of the illustrations in the book show women in labor with the pubic and vulvar hairs untouched. In this country almost all women have these hairs shaved off or clipped with scissors during labor. These minor criticisms however, should not detract from the excellence of the book. It is one of the best textbooks on obstetrics in the English language. The seventh edition will undoubtedly prove to be even more popular and valuable than the previous editions because Solomons has presented in this book the results of his huge experience gathered over a period of many years.

A Textbook of Applied Biochemistry for Pharmacists and Pharmaceutical Students. By Frank Wokes BSc PhC FIC Member of the Staff of the Pharmacological Laboratories College of the Pharmaceutical Society of Great Britain. Cloth Price \$5. Pp 522 with 79 illustrations. Baltimore William Wood & Company 1937.

This volume was written expressly for the pharmacist and pharmaceutical student in England. The recent high standard of educational requirements in pharmacy have created a field for books on biochemistry which meet the specific needs of this field. Accordingly, this book is concerned with the various applications of biochemistry in pharmacy and allied branches of public health. The material is concisely presented. It covers the usual list of subjects given in a syllabus of biochemistry besides more specifically the subjects which should be of special interest to the pharmaceutical student and pharmaceutical chemist. In the opening chapter on the biochemical importance of water the author discusses not only the information of general biochemical interest but also methods of removing water from drugs, variations in moisture content of various drugs, and so on. The succeeding chapters are terse but comprehensive discussions of hydrogen ion concentration, surface phenomena and colloids, spectroscopy and ultraviolet radiation (photochemistry and photosynthesis). In the chapter on bacteria the author discusses sterilization methods and germicides after considering information of general bacteriologic interest. The chapters on hormones and vitamins are well done and contain essential information, in brief, that is of interest to the pharmaceutical student and chemist. At the end of the book is a well selected bibliography.

An Investigation into Questions of Social Hygiene in the Counties of Västernorrland and Norrbotten Sweden. Conducted with the Support of the Royal Medical Board in 1929-1931. Published in Swedish in 1934. English partly revised edition. Paper. Various pagination with illustrations. Lund Håkan Ohlsson 1937.

The conditions affecting health in the two farthest north provinces of Sweden were subjected to detailed examination, with special emphasis on diet, housing and school environment. It was discovered that significant vitamin deficiencies could be easily remedied by a somewhat more extensive use and better preparation of certain native berries. The population of the district in 1931 was 407,096. More attention is given to public and private health organizations than to the work of physicians, and it would appear that these various societies and public institutions and nursing services are depended on for a large share of the health care. One general impression seems quite clear, that in spite of the subsidized physicians and salaried medical officers nearly all the problems of rural medical service that trouble the United States are still more or less serious problems in these districts. State grants in aid of district medical services are given only to districts with a population of about 3,000, and the context would indicate that one physician is expected to serve a population of this size.

Allergy Its Practical Application. By J A Rudolph MD Associate Clinician in Charge to the Department of Allergy Mt Sinai Hospital, Cleveland Ohio. Expressly Prepared for Physicians and Students of Medicine Containing Practical Points Necessary for the Care of Patients with Asthma Hay Fever Urticaria Eczema and Other Allergic Conditions. Cloth Price \$3. Pp 224. Philadelphia Dorrance & Company 1937.

This small book is intended to furnish students and practitioners of medicine practical aid in the care of patients suffering from asthma, hay fever and other allergic conditions. In this aim the author has succeeded to a considerable extent. The chapter on house dust and that relating to allergy of the skin are good. The chapter on immunology is brief and there is an almost complete absence of directions regarding dosages used in hyposensitization. The necessity of correlating clinical observations with skin tests is well emphasized. The book unfortunately has some serious defects. The author tends to be dogmatic in several instances, e.g., on page 66 "delayed reactions are of no importance." Other errors appear, e.g., on page 76 Scheppegrell is given credit for first attempting a pollen survey (1917), whereas Blackley's work preceded this some fifty years. On page 81, tree pollen is not mentioned at all as a cause of hay fever in the Central states. On page 136 the use of calcium in asthma is opposed as not all beneficial, yet in 1936 the author wrote an article favoring the use of calcium.

A serious shortcoming is the complete absence of references to recent literature. No article published after 1934 is mentioned and therefore the book is so out of date that it omits entirely such subjects as the valuable oral use of 1:100 solution of epinephrine in asthma.

Mikromethodik. Quantitative Bestimmung der Harn, Blut und Organbestandteile in kleinen Mengen für klinische und experimentelle Zwecke. Von Ludwig Pincussen. Sixth edition. Boards. Price 5 marks. Pp. 193 with 31 illustrations. Leipzig & Vienna: Franz Deuticke, 1937.

This edition attests the popularity of Pincussen's work. It varies from the preceding only in the revision of several methods and the addition of a few of the newer methods. The book begins with a clear, simple statement of the principles involved in measuring and weighing, colorimetric methods, and nephelometry. Then follow sections on the quantitative determination of the common inorganic and organic constituents of urine, blood, tissue and feces. These are followed by a section on blood examination by gas analysis and a few pages on the determination of hydrogen ion concentration by means of indicators. A subject index follows. The methods are clearly stated under the headings of principle, reagents, procedure, calculation and example. Some of the methods vary from those commonly used in routine clinical analysis. The book is therefore a welcome addition to the library of those who read German, as a supplementary manual on alternate methods for special routine analyses on small quantities of material as well as for research procedures.

The Common Neuroses. Their Treatment by Psychotherapy. An Introduction to Psychological Treatment for Students and Practitioners. By T. A. Ross, M.D., F.R.C.P. Second edition. Cloth. Price \$4. Pp. 236. Baltimore: William Wood & Company, 1937.

To the practitioner of medicine this book is commended. It provides an insight into the etiology and therapy of the psychoneuroses contained in no other book. The author does not limit himself to any single approach in his attempt to understand and treat the psychoneuroses. "Most books now in circulation are pledged to some particular method, and there has been little recognition of the possibility that different methods of treatment may be used to advantage in different types of illness and for different individual patients." His critical analysis of Freud is heartening. He utilizes Freudian mechanisms in his therapy and acknowledges Freud's contributions to the bodies of philosophic and psychologic knowledge, but he feels, in common with many others, that Freud's contribution is not basically a therapeutic one. The book should prove of inestimable value to the general practitioner, who sees, and will continue to see, the great bulk of functional and nervous disorders.

Quelques vérités premières (ou soi-disant telles) en pathologie cardio-vasculaire. Par E. Donzelot, professeur agrégé de pathologie médicale à la Faculté de médecine de Paris. Collection publiée sous la direction de MM. L. Ombredanne et N. Flessinger. Boards. Price 24 francs. Pp. 82. Paris: Masson & Cie, 1937.

This little brochure contains a series of short generalizations designed to state definite facts on disorders of the heart and blood vessels. The first portion deals with cardiac arrhythmias, angina pectoris, endocarditis, myocarditis, myocardial infarction, congenital cardiopathies and cardiac insufficiency. The second portion is concerned with vascular abnormalities such as arterial and venous abnormalities and hypertension. Myocardial infarction is dealt with as follows: "The clinical syndrome is extremely variable but can be grouped into two types, one in which anginal pain predominates and the other characterized by cardiac insufficiency. The anginal form is characterized by four essential signs: pain, fall of arterial blood pressure, pericardial friction rub and fever. Pain opens the scene brutally, is agonizing and persists for hours or even days; it is also literally insupportable. Fever appears typically on the second day, is constant, and oscillates between 38 and 38.5 degrees C. It is accompanied by leukocytosis." The booklet should be of interest to medical teachers of cardiovascular disease, who may find in the short, pithy statements which are regarded by the author as "primary truths," texts around which amplifications of the subject may be developed.

Measurements of Ultraviolet Radiation and Illumination in American Cities During the Years 1931 to 1933. By James E. Ives, Senior Physicist, and W. A. Gilt, Assistant Chemical Engineer, Office of Industrial Hygiene and Sanitation, U. S. Public Health Service. Prepared by direct order of the Surgeon General, U. S. Treasury Department, Public Health Service. Public Health Bulletin No. 233. Paper. Price 10 cents. Pp. 35 with 11 illustrations. Washington, D. C.: Suppl. of Doc. Government Printing Office, 1937.

In the work reported in this bulletin, horizontal surfaces were used for registering measurements. A Macbeth illuminometer, provided illumination figures, while ultraviolet measurements were made with a meter developed by Rentschler. The authors believe that the two main contributions of their study are first, its general nature (measurements were taken in fourteen cities of widespread geographic distribution: New Orleans, Los Angeles, San Francisco, St. Louis, Washington, Baltimore, Philadelphia, Pittsburgh, New York, Cleveland, Chicago, Detroit, Boston and Buffalo) and, second, the determination of the ratio of the antirachitic ultraviolet shorter than 313 millimicrons to the illumination.

Maladies des femmes enceintes. III. Affections de la peau. Par Henri Vignes, professeur agrégé à la Faculté de médecine de Paris. Avec la collaboration de F. Hanouin et G. Vial. Paper. Price 25 francs. Pp. 404 with 4 illustrations. Paris: Masson & Cie, 1937.

Maladies des femmes enceintes. IV. Affections des muqueuses génitales. Par Henri Vignes, professeur agrégé à la Faculté de médecine de Paris. Paper. Price 24 francs. Pp. 125. Paris: Masson & Cie, 1937.

These two volumes are the third and fourth in the series of books prepared by Vignes on the illnesses that may occur during pregnancy. In volume III the author takes up diseases of the skin and in its seventeen chapters he discusses the entire field of dermatology that may be associated with gestation. Volume IV deals with the affections of the mucous membranes of the vagina and cervix. As was emphasized in the review of the first two volumes (*THE JOURNAL*, May 2, 1936, p. 1596) the books are encyclopedic in character. The author has thoroughly reviewed the world literature on the subjects he discusses and he summarizes it in excellent fashion. Large sections of each book are devoted to therapy, hence these books should prove to be of great practical value as well as indispensable sources of reference.

Diseases of the Nose and Throat. A Textbook for Students and Practitioners. By Sir St. Clair Thomson, M.D., F.R.C.P., F.R.C.S., Consulting Surgeon for Diseases of the Throat, King's College Hospital, London, and V. E. Negus, M.S., F.R.C.S., Surgeon for Diseases of the Throat and Ear, King's College Hospital, London. Fourth edition. Cloth. Price \$14. Pp. 976 with 415 illustrations. New York & London: D. Appleton Century Company Incorporated, 1937.

Thomson's book has always been a popular one, having passed through three editions since its first publication in 1911. The present edition discloses V. E. Negus in the role of co-editor and contributor, he having rewritten the subject of peroral endoscopy into a new and separate chapter. Several discarded procedures, such as the Kilian operation and intubation of the larynx, have been curtailed in the text to make way for more generally accepted procedures. Experience in the use of the bronchoscope has led to more detailed description of pulmonary and esophageal conditions than is found in the earlier editions. On the whole, the book follows its predecessors rather closely as to the material and its arrangement, offering nothing that is revolutionary but keeping up with recent trends. Like many textbooks that come to us from our English confreres, it is particularly replete with therapeutic minutiae and is therefore the sort of book one likes to refer to frequently when cases fail to respond to a favored routine. To those who are acquainted with the earlier editions there is little more to be said. To those who have not had that pleasure, it may be safely recommended as a valuable addition to a practical library.

Assessment of Risks in Life Assurance Practice. By Jehan, Jr., J. F., M.D., L.R.C.P., L.R.C.S. Paper. Pp. 18. Bombay: The Author, 1937.

This is the kind of pamphlet that many life insurance companies prepare for distribution to newly appointed examiners. The value may be doubted considering such statements as "The mortality from all diseases on the whole is said to be greatest among clerks." "Family history of tuberculosis is the most widespread cause of extra rating."

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts **Compensability of Tuberculosis Contracted by Nurse**—The claimant was employed from June 1930 to November 1934 as a nurse by the Murdale Sanitarium of Milwaukee County, Wis., a sanatorium for tuberculous patients, her work requiring her to come in close personal contact with the patients. In October 1934 she contracted a cold, tuberculosis developed and she applied for compensation under the workmen's compensation act. The examiner for the commission found that the nurse had not contracted tuberculosis in consequence of performing services growing out of and incidental to her employment and dismissed her application for compensation. The industrial commission set aside the examiner's findings and awarded compensation. The county of Milwaukee instituted proceedings to set aside the award of the industrial commission and from an adverse judgment in the trial court the county appealed to the Supreme Court of Wisconsin.

The county contended, among other things, that there was no evidence to sustain the finding of the commission. But, said the court, one physician testified that the nurse probably contracted tuberculosis while working at the sanatorium. The testimony of another medical witness, while not so definite, was open to the inference that the nurse did not have active tuberculosis at the time she entered the employ of the county. A third medical witness testified that a long and continued exposure to tubercle bacilli is a very important factor in reactivating an old lesion. There was, the court said, sufficient competent evidence to sustain a finding either that the nurse did not have tuberculosis or had an arrested case of it at the time of her employment by the county and that the work at the sanatorium either reactivated the disease or constituted its original cause. In either event, the nurse would be entitled to compensation. The award of compensation was affirmed—*Milwaukee County v Industrial Commission (Wis.)*, 272 N W 46.

Optometry Practice Acts **Writ of Prohibition to Restrain Revocation of License for Untrue Statement in Advertising**—The California optometry practice act authorizes the state board of optometry to revoke the license of a licensee for "the advertising of optical business or treatment or advice in which untruthful, improbable or impossible statements are made." The board initiated proceedings against the plaintiff to revoke his license, alleging that his advertisement in a local newspaper contained untruthful and improbable statements in that he offered for sale complete glasses containing single vision lenses and including frames and examination for \$7.50 and that he refused to sell to persons answering the advertisement the advertised glasses for the price stated. Prior to the hearing, the plaintiff instituted proceedings for a writ of prohibition, in the superior court, Los Angeles County, to stay the proceedings. A judgment obtained by the plaintiff was affirmed by the district court of appeal, second district, division 2, California (60 P (2d) 196), and the case was transferred to the Supreme Court of California for consideration as to the propriety of the issuance of the writ of prohibition.

The office of the writ of prohibition, said the Supreme Court, is limited by the constitution to the restraint of a threatened exercise of the judicial power in excess of jurisdiction. It does not lie to an officer or board exercising purely ministerial functions. The optometry act provides for a state board of examiners in optometry having state-wide jurisdiction over the practice of optometry. Such a board in the opinion of the court, actually engages in enforcing administrative determinations and does not exercise a judicial function. Agencies engaged in making administrative determinations, unlike courts, have the power and the facilities to investigate and initiate action and, more or less informally, find the facts which under the law justify a course of action. They cannot and do not declare the law but perform the sole duty of ascertainment. Under this theory neither a writ of prohibition nor a writ of certiorari may be utilized to review the determinations of the

board. Furthermore, the court was of the opinion that the petitioner was not entitled to any relief on the showing made. He was accused of making untruthful statements in his advertisements. No evidence was taken inasmuch as the present proceeding was instituted before the time set for the hearing. We can appreciate, the court said, that under certain testimony it might be proved that the advertisement was not an untruthful statement, whereas, under other circumstances, it would be demonstrated to be untruthful and intentionally drawn to mislead. Certainly, the court said, untruthful advertising should be held to constitute an untruthful statement. Under such circumstances, the board should be permitted to proceed with the hearing. Accordingly, the judgment for the petitioner was reversed—*Whitten v California State Board of Optometry (Calif.)*, 65 P (2d) 1296.

Evidence Admissibility of Paraffin Mold Used in Gunpowder Test—The defendant, Westwood, was convicted of murder and appealed to the Supreme Court of Pennsylvania. He contended, among other things, that the trial court erred in admitting in evidence a paraffin mold of his hand and the testimony of expert witnesses that certain black specks on the mold constituted residues of gunpowder.

Shortly after the homicide, an assistant county detective made a "paraffin test" of the right hand of the defendant. Hot paraffin was placed next to the skin. Cotton was placed on that and then another coat of paraffin added. The paraffin was then lifted and later subjected by two chemists to the "diphenylamine test" or "lungee reaction." This was described as "a reaction primarily for nitrates and certain other oxidized substances." Gunpowder was said to be rich in nitrates. One of the chemists testified that a microscopic examination had revealed the presence of small black specks on the mold and that applying one or more drops of the "lungee reagent" to these specks "an intense blue color with comet tail formations was immediately apparent." This witness further testified that he had applied the reagent to gunpowder and an identical reaction had resulted. Another chemist, in answer to a hypothetical question, testified that the specks on the mold were residues of gunpowder. An expert witness for the defendant, also a chemist, testified that he had found, as a result of experimentation, that the following substances would give a "blue reaction" when the "diphenylamine test" was applied: ordinary soot, sodium perborate tooth powder, Pebecco toothpaste, cigar ashes, cigaret ashes and different kinds of matches. In his opinion, the "paraffin test" to detect the presence of gunpowder was not infallible. The Supreme Court of Pennsylvania, however, held that the mold and the expert testimony with respect to it were admissible in evidence. The judgment of conviction was affirmed—*Commonwealth v Westwood (Pa.)*, 188 A 304.

Malpractice **Shortening of Leg After Fracture**—The plaintiff as a result of an automobile accident sustained, among other injuries, a compound comminuted oblique fracture of his right femur about 2½ inches above the knee. He was removed to a hospital and there attended by the defendants. The physicians made a temporary reduction of the fracture and applied immobilizing agents. Five days later an operation was performed and a Lane bone plate, fastened with five one-half inch screws to the bone, was used to keep the fragments in apposition. After the operation the leg was encased in a board splint, and a Buck's extension was applied. An infection subsequently developed. Some of the screws that held the Lane plate gave way, causing the plate to become loose and permitting the fragments of the femur to overlap. As a result, the plaintiff's right leg was about 3 inches shorter than his left. He instituted a suit against the defendants for malpractice, claiming damages in the amount of \$40,000. The jury returned a verdict for the physicians but on motion of the plaintiff the trial court set aside this verdict and granted a new trial on the ground that erroneous instructions had been given the jury. The physicians thereupon appealed to the Supreme Court of Missouri, division No 2.

The instructions that were given the jury, erroneously in the opinion of the trial court, told the jury that no expert witnesses could testify concerning external appearances and manifest conditions observable by every one but that in the present case

the question was one of medical and surgical skill to be determined by the opinions of the medical experts and that the jury should not consider the opinions of laymen with respect to the matter. The contention seemed to be that this instruction unduly singled out for comment the opinion testimony of the expert witnesses, thereby usurping the functions of the jury. With this contention the Supreme Court disagreed. The present case, the court said, was tried on the theory that the issue of negligence revolved around the degree of care and skill ordinarily possessed and exercised by physicians and surgeons in good standing in the same or similar communities in the treatment of similar injuries. Whether or not the fracture board that caused pain in the patient's hip should have been removed to relieve the pain within a few days after the performance of the admittedly successful surgical operation, at the possible sacrifice of the successful results theretofore secured and the risk of further complications, was a matter to be determined from the testimony of witnesses possessing the necessary qualifications required through study, training and experience, and not from the testimony of the ordinary layman. So also with respect to the patient's contention that a fall from a bedpan to the mattress ten or twelve days after the operation loosened the Lane bone plate and refractured the femur. While, continued the court, malpractice cases exist wherein expert testimony is not indispensable to the establishment of negligence, the present case was not such a case. Proper instructions, therefore, with respect to the weight to be accorded the testimony of experts were justified.

Juries should not be permitted to say that the method of treating an injury of the nature here involved was negligent despite the fact that the evidence showed that the uniformly adopted practice of the most skillful surgeons had been followed. The mere fact that injury follows negligence, the court pointed out, does not necessarily create liability. The burden rested on the plaintiff to prove by substantial evidence that the physicians in the present case were negligent as charged and to prove the necessary causal connection between such negligence and the injury. If the evidence merely tended to prove that the injury might have resulted from several causes for some but not all of which the physicians were liable, the necessary causal connection remained in the realm of conjecture and speculation. All that the evidence disclosed with reference to the shortening of the patient's leg was that it might have resulted from one or more of several causes. In the opinion of the Supreme Court, the verdict of the jury for the physicians was a correct one and the trial court should have entered judgment on it. The cause was therefore remanded with directions to the trial court to reinstate the verdict of the jury for the physicians and to enter judgment thereon.—*Pedigo v Roseberry et al (Mo)*, 102 S W 2d 600

Privileged Communications. Testimony of Patient Constitutes a Waiver of Privilege.—The defendant insurance company promised to pay certain benefits to the plaintiff in event he became totally and permanently disabled if such disability was not due to a progressive, incurable ailment with which he was afflicted prior to the issuance of the insurance policy. The plaintiff became blind and sued the insurance company on the latter's refusal to pay the promised benefits. From a judgment in favor of the plaintiff, the company appealed to the court of appeals of Ohio, Licking County.

At the trial, the plaintiff claimed that "his eyes went bad" following the "flu" four years after the issuance of the policy. He voluntarily testified as to the nature of his disability. On cross-examination he admitted that he had consulted certain physicians about his eyes and stated that they examined his eyes and fitted him with glasses. The trial court refused, on the theory that a privileged communication was involved, to permit the defendant insurance company to prove by the testimony of these same physicians that the plaintiff's disability was the result of a disease, retinitis pigmentosa, that existed prior to the issuance of the policy. They would have testified that they discovered the disease when they examined the plaintiff's eyes. The insurance company contended that this testimony should have been admitted because the plaintiff had waived the privilege when he voluntarily testified relative to the consultation with these physicians concerning his eyes. In *Ausdenmoore*

et al, Ex'rs v Holzback, 89 Ohio St 381, 106 N E 41, and the court of appeals, it was held that a privileged communication may arise not only by word of mouth but by exhibiting the body or any part thereof to a physician for his opinion, examination or diagnosis, and that such privilege can be waived by either the express consent of the patient or his voluntary testimony as to the things and matters communicated to his physician. In the present case, therefore, the information communicated by the plaintiff to the physicians when he exhibited his eyes to them for examination constituted a privileged communication. This communication might have remained privileged, but when the plaintiff voluntarily testified, in his own behalf, "they examined me for the purpose of fitting me with glasses," he waived his privilege. In the opinion of the court of appeals, the trial court erred in rejecting the proffered testimony. The judgment of the trial court was therefore reversed and the case remanded.—*Metropolitan Life Ins Co v McKim (Ohio)*, 6 N E (2d) 9

Eugenic Sterilization. Fertility Despite Ligation of Vasa Deferentia.—Bastardy proceedings were instituted against the defendant, charging him with being the father of the relation's child. At the first trial a verdict of guilty was set aside by the court and a new trial granted. At the second trial the defendant was convicted of bastardy. The defendant's motion for a new trial on the ground of newly discovered evidence was denied and he appealed to the appellate court of Illinois, third district.

At the second trial the testimony that a physician gave at the first trial was permitted to be read. According to this testimony the physician, years prior to the alleged relationship between the defendant and the relation, had "sterilized" the defendant, at which time "both vasa were divided by the ligatures and separated." This witness stated that he had never known this kind of an operation to fail to accomplish its purpose. A medical witness for the relation, however, testified that ligation of both vasa deferentia would not necessarily prevent a man from begetting a child, that a simple tying off of a vas deferens would obstruct that duct for the time being but that the duct would reestablish itself after the absorption of the ligature. At the time of his motion for a new trial following his conviction, the defendant presented an affidavit of the physician who had operated on him to the effect that he had not only doubly ligated each vas deferens of the defendant but in addition had removed a section, approximately three-eighths inch in length, from each duct. An affidavit of another physician was also presented in which the affiant declared that the operation as described by the operating physician in his affidavit would, to a reasonable degree of medical certainty, produce sterilization. The defendant claimed that he was entitled to a new trial because of this "newly discovered" evidence.

The appellate court held, however, that the trial court had not erred in refusing to grant the defendant a new trial on the ground of newly discovered evidence because the defendant had not satisfied the court that, as is required by the law of Illinois, the evidence could not have been produced at the trial by the use of reasonable diligence. The court was of the further opinion that the jury was warranted in finding from the evidence presented at the second trial that the defendant was the father of the child. Accordingly, the appellate court affirmed the judgment of conviction.—*People ex rel Oemke v Schuring (Ill)*, 6 N E (2d) 217

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1927 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Host Susceptibility to Common Colds—Spiesman and Arnold discuss their experimental and clinical observations on common colds. Sixty-three patients observed over a period of three years were selected from the outdoor clinic patients after having had a long history of various types of treatment. The patients finally chosen for this study presented no detectable pathologic conditions as determined by a complete history and by physical and x-ray examination of the sinuses and the chest. The individual suffering from repeated colds between October and April has been found to have an altered vasomotor reaction of the upper respiratory mucosa to thermal stimuli applied to the skin. When the skin is chilled there is a slow, gradual vasoconstriction of the capillaries in the mucosa of the upper part of the respiratory tract which persists for from several minutes to two hours. This represents a maladjustment of the peripheral capillary response to climatic or meteorological environment. So long as this abnormal reaction exists the host is susceptible to the common cold virus and the bacterial flora residing in the upper part of the respiratory tract. The vasomotor response could not be altered nor the incidence of common colds reduced in this group by vaccine therapy. But hydrotherapy and certain simple alterations in the diet accomplished both. The best results were obtained by a combination of the two methods of prevention. The hypersensitive or allergic type of cold is more difficult to control than the chronic, frequent and severe head cold type. The nutritional factor in susceptibility to common colds has been frequently observed during the study. It seems that the mucosa of the nose is more sensitive to allergens ingested by mouth than the skin. The nonallergic diet helped the hypersensitive group to readjust its vasomotor responses. The authors have no explanation to offer for the beneficial results obtained in the frequent infectious head cold group following the elimination of wheat breads, pastries, pies and cookies. Their experience convinces them that these foods increase the susceptibility of the sufferer from a chronic cold to repeated attacks and exercises a detrimental influence on the nasal vasomotor response to thermal cutaneous stimuli. The reservoir for the causative agent of common colds is in the main, confined to the chronic, frequent and repeated head cold subjects. The restriction of the distribution of this virus can best be approached by increasing the resistance of these people to auto-infection. This group responds to preventive and hygienic procedures better than the hypersensitive group.

The hypersensitive type of disturbance of the upper part of the respiratory tract is not communicable and from the standpoint of public health is not a source of contagious material. The person with the repeated or chronic type of common cold is out of adjustment to his environmental factors and hence requires some corrective measures to assist in adaptation, such as vasomotor stimulation (hydrotherapy), certain dietary restrictions or better mental hygienic control. While in a state of maladjustment, this portion of the population acts as reservoirs for the virus of the common cold. The extent or magnitude of the maladjustment of sufferers of the chronic or frequent cold differs in individuals. Some will find that retaining the vasomotor reflex response by hydrotherapy will be sufficient to prevent colds. Some will find the nutritional factor most important. Others will find the mental factor to be of major importance.

Hypertensive Meningeal Hydrops—From 1929 to 1935, at the Neurological Institute, Davidoff and Dyke isolated fifteen cases that presented a uniform clinical and encephalographic syndrome, consisting of signs of increased intracranial pressure, that is, increased spinal fluid pressure, headache and papilledema, but seldom vomiting. The oldest patient was 43 and the youngest 4½ years of age, eleven were females. Four patients gave a history of otitis media, one had a long history of chronic illness in which a focus of infection was sought and several organs had been removed, one gave a history of pneumonia complicated by thrombosis of the femoral vein followed by ulceration of the leg, one had attacks of cholecystitis, one patient had a four plus and another a one to two plus Wassermann reaction of the blood but their spinal fluid Wassermann tests were negative, and six patients gave no history or evidence of infection that could be considered related to the present illness. In practically all the cases the principal symptoms were headache in eleven cases, failing vision in ten, vomiting in five, tinnitus in four and dizziness in two. Diplopia was present in three cases. The duration of the symptoms varied from two years to twelve days. The chief sign in all these cases was papilledema, often of a high degree, that is, from 3 to 6 diopters. The spinal fluid showed a normal cell count in all but one case, in which 66 cells were present. The total protein was normal with the exception of one, in which 75 mg per hundred cubic centimeters was present. The gold curve was negative in all cases. Tests for globulin were negative except for one plus in the case presenting the high cell count. Plain films of the skull showed evidence of increased intracranial pressure in ten cases. In twelve of the fourteen cases in which air studies were made the air was injected directly into the ventricles because of the papilledema. A high percentage failed to show satisfactory filling on direct ventriculography, which can be explained by the small size of the ventricles and the high intracranial pressure. This combination the authors believe resulted in expulsion of the gas along the tract of the needle when ventriculography was used. Evidence of this mechanism was found. Thirteen of the fifteen patients were treated by subtemporal decompression. One, a child, showed some ataxia on clinical examination and underwent a suboccipital exploration and decompression, one had no operation whatever. In addition, the patients were treated by dehydrating measures, consisting

of limitation of fluid intake, saline cathartics or retention enemas, and intravenous hypertonic dextrose solution when indicated. All the patients improved during their stay in the hospital. After they left the hospital the dehydrating measures were continued at home, and improvement continued, but final disappearance of the papilledema required from six months to several years, with occasional recurrence of headache.

Present Needs in the Public Health Control of Gonorrhea—Parran maintains that the ultimate attainment of success in the control of gonorrhea lies in the vigorous prosecution of research work, particularly laboratory experiments which may be correlated with clinical research. He recommends that the furtherance of research work in gonorrhea is the immediate objective. The United States Public Health Service will cooperate in this. Before any new method is accepted in the future it should be studied critically in order to determine whether it is one of real merit.

Treatment of Early Syphilis with Artificial Fever and Chemotherapy—With the hope that time and expense might be lessened and that the disastrous late complications of syphilis might be prevented, Simpson and Kendell subjected thirty-four patients with primary and secondary syphilis to combined fever and chemotherapy. The usual course of fever therapy in all but six of these patients consisted of approximately fifty hours of sustained rectal temperature between 105 and 106 F, the average being 105.8 F. The artificial fever therapy was administered at approximately weekly intervals

for a period of ten weeks. With the exception of two patients who exhibited idiosyncrasy to chemicals, the usual course of chemotherapy consisted of thirty injections of bismuth arsenamine sulfonate each containing 0.2 Gm, or thirty injections of neoarsphenamine, each containing 0.3 Gm, and thirty injections of a bismuth compound, each containing 0.2 Gm of metallic bismuth. No essential difference was observed in the response of the patients treated with bismuth arsenamine sulfonate or neoarsphenamine and bismuth. The first ten intravenous injections were administered one-half hour before the fever treatment was begun. The injections of bismuth were given intramuscularly just before each fever session was started. Injections of chemotherapeutic agents were then given at weekly intervals for a period of twenty weeks at the conclusion of the course of combined fever-chemotherapy. The injections of neoarsphenamine and bismuth were given concurrently. Ordinarily, the standard diagnostic tests remained strongly positive during the first four to six weeks of combined treatment. During the same interval the Kahn quantitative units would ordinarily exhibit a rise after the first treatment and a progressive decline during the next four to six weeks. The combined therapy appears to intensify the curative action of the chemotherapeutic agents. Fever therapy alone or chemotherapy alone, as applied to control groups of patients, was inadequate in a high proportion of cases. In certain instances in which syphilitic lesions progressed in spite of chemotherapy, these lesions began to heal promptly after fever therapy was instituted. The response of certain patients who received a relatively short course of fever therapy, combined with chemotherapy, suggests that an equally favorable outcome might result from a shorter course of fever therapy in those patients who exhibit a prompt and uniform decline in the serologic reactions as measured by truly quantitative tests. Conversely, it is quite apparent that certain patients will require larger amounts of fever therapy or chemotherapy, or both.

Nontumorous Cysts of Maxilla—Rosedale and Koepf report seven cases of maxillary cysts of dental origin. Six of these encroached on the antrum. One was complicated by an osteoma, and in one case impacted teeth were present within the cyst. Supernumerary teeth were present in two others. In two cases the cyst became manifest after extraction of teeth, and two were associated with carious teeth. The other three were of follicular origin. Cysts of dental origin, other than those resulting from adamantinomas, are usually designated as follicular or radicular cysts. The former are those which are associated with the second dentition. Their presence often can be suspected from defects in the dental arch due to uncrusted or supernumerary teeth. They are symptomatic unless of large size or infected, and are most often discovered by x-ray examination. Radicular cysts are always found in connection with infection at the root of a devitalized tooth. They do not contain teeth. Both types of cyst may be infected or noninfected and the contents may vary from fluid to semi-solid amorphous material. Enlargement in either type may cause secondary devitalization of neighboring teeth. Periapical

infection is considered the exciting influence in the development of radicular cysts. The usually accepted theory of the development of a follicular cyst is that it results from the hollowing out of the follicle of an unerupted tooth. There are many theories regarding the histogenesis of cysts of dental origin, each of which has ardent testimony in behalf of its validity. However, when critically scrutinized, none of them seem to conform to usually accepted pathologic concepts. The treatment of these cysts should consist of removing the cyst by blunt dissection through an intra-oral incision made over the point of greatest swelling. The remaining cavity is then connected to the nose through a large window under the inferior turbinate. The first incision is sutured. The cavity is irrigated through the antroanasal window. This type of treatment tends to result in less deformity and discomfort and more rapid healing than packing and irrigation through the intra-oral incision.

Trinitrophenol-Calcium Carbonate Treatment in Sinus Infections.—Gray believes that chronic infections of the accessory sinuses, wherein there is often an associated osteomyelitis (caries or necrosis) in varying degrees, may be considered analogous to chronic osteomyelitis. Irrigations of various solutions, for their antiseptic and healing effects, have been unsuccessful in the treatment of chronic infected sinuses, particularly the maxillary sinuses. The maggot treatment cannot be used, and the extract, if known to the patient, would be objected to if not considered undesirable by the physician. The Stewart treatment (trinitrophenol-calcium carbonate) offers a desirable method of treatment when preliminary operative work, debridement and proper drainage, has been done. Since there is a precipitate formed between the trinitrophenol-calcium carbonate of a fine nature, a sufficiently large opening must be made to allow use of the Stewart method of treatment in selected cases of chronic conditions of the ear and nose (accessory sinuses). The trinitrophenol solution is easily sprayed into the opened sinuses by use of an atomizer equipped with the long, slender, detachable spray tip (which may be sterilized). The tip can be easily curved to insert through the opening especially through a naso-antral opening, into the maxillary sinus. The calcium carbonate suspension is applied in the same manner. The surroundings must be kept as aseptic as possible during treatment. Contrary to other methods, the trinitrophenol-calcium carbonate alleviates existing pain. It is well tolerated by the patient from a psychic as well as physical standpoint. Four case histories are submitted that demonstrate the value of the foregoing method. Granulation tissue formed promptly, purulent discharge was rapidly reduced, healing was rapid, pain and discomfort were minimized, and the residual scar was less marked than that with any other method of treatment, excepting the maggot treatment. It also produced rapid healing in chronic wounds of the flesh in addition to chronic bone conditions.

Results of Vaccination Against Colds.—The student health department of the University of Pennsylvania decided to give prophylactic vaccination against colds to those students who wished to give this treatment a trial. Houser reports that in the last four years 108 students have been so treated. A series of nine injections of the following doses was given to each subject 0.1 cc, 0.2 cc, 0.3 cc, 0.4 cc, 0.5 cc, 0.6 cc,

0.7 cc, 0.8 cc and 1 cc of a stock vaccine. The smaller doses were given every three to five days, whereas the doses above 0.5 cc were given at weekly intervals. In no case did any constitutional reaction occur. Many complained of slight soreness of the arm, which usually disappeared in from twenty-four to forty-eight hours. A few experienced transient symptoms of an acute cold within the forty-eight hours following injection. In 1936 and 1937, questionnaires were sent to members of the group who were inoculated. Although ninety-four replies were secured to the questionnaires, only eighty-six could be included in the final report because only three months had elapsed since the completion of the series of inoculations for the eight persons whose answers were discarded. On tabulation of the results, it was found that in this group the total number of colds was 479 in the years prior to treatment and 181 in the year subsequent to treatment. The total number of days for the group during which they suffered from colds dropped from 5,160 a year before treatment to 1,666 in the year after vaccination. Of the eighty-six subjects, sixty-eight reported improvement subsequent to treatment. Of this group, fifteen had no colds during the winter following the series of injections. Eighteen were improved in no way by the injection. Of the eighty-six students, only twenty-eight were completely free from any local condition that might be considered a predisposing factor, such as the granular posterior pharyngeal wall studded with lymphoid islands, slight nonsuppurative sinusitis or a borderline nasal deformity. Of this group, twenty-five were improved. The greatest improvement occurred in reducing the severity and duration of colds rather than in eliminating them. This would be in keeping with the virus causation, for, if this is the method of production of most colds, one certainly could not expect to prevent their occurrence by the administration of a bacterial vaccine, but the chances of influencing the secondary stage, in which bacteria play a prominent part, might be considerable. Until something better is available it seems worth while to continue this form of therapy. There is little evidence that colds are prevented by this type of therapy.

Chylous Effusions and Ligation of Superior Vena Cava.—Robinson and his co-workers found references to 100 cases in which the diagnosis of chylothorax seems to have been correct. In eighty-three of these cases the data on the cellular content of the fluid and on the changes in the cell picture in the blood stream have been meager. Although somewhat more complete, the chemical studies on these fluids have also been inadequate. Therefore thirteen differential blood counts were made in ten of the reported cases of chylothorax. The total white blood cell counts varied from 4,000 to 25,000. In six instances there was a high proportion of lymphocytes, while in seven the lymphocytes varied from 6 to 16 per cent. The authors had previously produced experimental chylothorax in twenty-one of thirty-six animals (dogs and cats), in each of which the superior vena cava was ligated. The present report is a continuation of that study, with particular emphasis on the chemical and cellular composition of the fluids. The cellular changes occurring in the blood stream as a result of the ligation of the superior vena cava are compared with the cellular picture of the chylous fluids. Eleven additional animals have been studied since that time. In twenty-eight animals of this group typical chylous effusions developed, in eleven fluid was obtained from the pleural cavities, which was, however, not chylous, and in eight animals there was no fluid. In all the experiments in which the superior vena cava was ligated it is assumed that the development of chylous effusions was dependent on the obstruction thus produced to the delivery of lymph from the abdominal viscera through the thoracic duct and its collateral

and anastomotic channels. Ligation of the superior vena cava has been found to produce milky fluids which are extremely rich in lymphocytes but which also contain neutrophils. In the circulating blood of animals the total number of lymphocytes and the total number of eosinophils drop markedly following ligation of the superior vena cava. The obstruction of lymphatic drainage is assumed to be of sufficient importance to account for the decrease in lymphocytes. Milky fluids produced by ligation of the superior vena cava in dogs are true chylous effusions the opacity of which is due to free fat. The lipids estimated as "neutral fat" comprise about 80 per cent of the total lipids. The quantities of free cholesterol are small but show a tendency to form a constant fraction of the total lipid. The esterified cholesterol, on the other hand, is less inclined to vary with the neutral fat. The total nitrogen values probably include nitrogen from nonlipid compounds. The aminonitrogen is mostly due to true lipids, and it tends to vary with the neutral fat. The phosphatide fraction contains substances that are neither lecithin nor cephalin. These, too, tend to vary with the neutral fats. The correlation between the phosphorus and aminonitrogen seems to indicate that they, to a large extent, rise and fall together.

Myasthenia Gravis—In fifty-one of the eighty-seven cases of myasthenia gravis under review, Kennedy and Moersch could not discover any cause that might be considered as a possible factor in the causation of the disease. In twenty-seven it appeared that some infection, such as a "cold," "flu," tonsillitis and pneumonia played a precipitating part, although the relationship of apparent cause and effect was not always clear. Recurring episodes of myasthenia gravis were frequently preceded by some acute infectious process. The ages of the patients at the time of the first onset of the symptoms varied from 10 to 77 years. The greatest number were in the third and fourth decades of life. There were forty-five male and forty-two female patients. The factor of race had no apparent significance. In no instance was there any evidence of either familial or hereditary factors. There was no close correlation between the occupation of the patient and the situation of the early muscular weakness. There was no special environmental or geographic characteristic. The length of time that elapsed between the onset of the first symptoms and the making of the correct diagnosis ranged from one month to twenty-five years and varied considerably. For the eighty-seven cases this period averaged 4.8 years. The appearance of the first symptom of myasthenia gravis and the appearance of the first objective sign of the disease paralleled each other rather closely. The ocular muscles were involved in 78 per cent of the cases, facial muscles and masseter muscles in 61 per cent, muscles of deglutition and phonation in 58 per cent, muscles of the arms in 29 per cent, muscles of the legs in 24 per cent and muscles of the neck and shoulders in 17 per cent. No unusual reflex disturbances were observed in any of the cases. The deep tendon reflexes were occasionally decreased or even increased but never absent. The spinal fluid was entirely normal in the

twenty-eight of the thirty-two cases in which it was examined. Not infrequently myasthenia gravis may present itself under the guise of marked general fatigue, but not every state of chronic fatigue is a form of myasthenia gravis. Twenty-seven patients had a complete remission which lasted on the average 2.2 years. Any accompanying illness exaggerates the existing symptoms and also tends to precipitate added myasthenic symptoms. There were thirty-four deaths. As neither any therapeutic measure of value nor any practical or consistent regimen for treating patients was available at the time, this mortality represents essentially that of the untreated disease.

Gynecologic and Endocrinologic Aspects of Sterility—Baron declares that in 70 per cent of the cases of sterility there is no single absolute cause and therefore the sterility is only relative. A relative sterility in one partner may be overcome by a high fertility in the other. Local genital abnormalities, the influence of constitutional depressions, the multiple incidence of etiologic factors and the division of responsibility between male and female are the causes given by Meaker. Many cases of sterility cannot be explained by present knowledge. Doubtless the newer advances in endocrinology and reproductive physiology will help to solve some of its problems. That a specific immunity exists in some cases is not beyond the realm of probability, since by changing partners conception often occurs after so-called previous sterile matings. Endocrinology, although promising as it may seem, can at best be only a partial factor as far as sterility is concerned. Only from 10 to 15 per cent, at most, of cases will be aided by endocrine preparations. The tide of enthusiasm which hailed the discovery of the sex hormones is receding. In the final analysis the major causes of sterility are still obstructive—whether congenital or acquired, through new growth or inflammation anywhere in the genital tract, from hymen to tubal fimbriae. Tubal closures are frequently the result of abortions which become mildly infected. They will remain only so long as knowledge of the control of conception is limited to the favored few. When birth control makes abortions unnecessary an important forward step will be made in preventive medicine and, paradoxical as it may seem, will have lowered the incidence of sterility. The major problem of sterility is a gynecologic and urologic one, and only by the continued cooperation of these two specialties will the greatest good be achieved.

Tetanus—Stewart declares that prophylaxis must not stop with tetanus antitoxin. The wound must be made unfavorable for the germ. Closed wounds must be eliminated and foreign bodies removed. Secondary infection must be controlled. It is only by debridement that foreign material and contused tissues can be seen and removed and punctured wounds made into open wounds. The mere injection of 1,500 units of tetanus antitoxin is no longer considered adequate treatment of contused or punctured wounds. Puncture wounds, such as nail wounds to the sole of the foot, should be excised and splinter wounds should be opened to their depth. The importance of readministration of prophylactic serum in deep and severely lacerated wounds and compound fractures is often overlooked. It is well to remember the ability of the spores of the tetanus bacillus to lie dormant and, since the serum remains in the body for only fourteen days, a second or even a third injection is frequently indicated. Clinical and experimental experiences have proved that antitoxin has no effect on toxin already fixed and causing symptoms. The intravenous administration (from 20,000 to 60,000 units in 300 cc of physiologic solution of sodium chloride) of serum is advised under general anesthesia or tribromethanol in amylene hydrate at the first suggestive symptom. Muscular spasm and reflex convulsions should be controlled as much as possible by sedatives. Adequate fluid and nourishment should be given by the nasal catheter and specialized nursing care in quiet isolation should be demanded.

Deficiency of Atmospheric Moisture as Factor in Prolonged Asthma—Parlato hopes to show that it is really the control of humidity which plays an important part in relieving asthmatic patients. He investigated the effects of the lack of sufficient moisture in the air and of raising the temperature during the colder months of the year, he concludes that a lack of sufficient moisture in the air or relative humidity in well heated homes and other indoor places during the colder months is an important factor in the causation of prolonged asthmatic attacks. The use of belladonna, stramonium and allied drugs often is contraindicated. The latter are to be used only with great caution. Their paralyzing action on the mucous glands of the respiratory tract aggravates and delays recovery from an asthmatic attack. Treatment calls for the immediate withdrawal of any of the foregoing drugs. Methods of supplying an adequate amount of moisture are described. With a normal relative humidity, patients responded more readily to the usual therapeutic measures which are used for the relief of asthma. Subsidence of prolonged asthma is more prompt and effective. A wider distribution of accurate air conditioners in homes, industry and business will provide a necessary and important means of maintaining a correct temperature and relative humidity, thus helping to reduce the number and duration of prolonged asthmatic attacks.

Concentration of Agglutinin in Vaccination Against Typhoid—During the last two years, Moor and Brown have carried out a comparative study of the oral and subcutaneous administration of typhoid vaccine in 187 human subjects. Agglutination titrations were made in all cases before the vaccine was administered and again four weeks after the last

dose. Typhoid vaccine administered orally produced as great or greater concentrations of agglutinin antibodies in the blood serum of human beings as that administered subcutaneously. The oral vaccine brings about this concentration of agglutinin antibodies in a shorter time. No reactions were observed following the administration of the oral vaccine. Severe reactions, causing loss of time from work, do occur when the vaccine is given subcutaneously. Generally subjects take the oral vaccine more willingly than they do the subcutaneous. Economically and practically the oral vaccine is more desirable than the subcutaneous.

Aspiration Biopsy and Distant Metastasis—McLean and Sugiura performed repeated aspiration biopsy on 155 rats and mice into which they had transplanted Flexner-Jobling rat carcinoma and mouse sarcoma 180. They observed that moderate or excessive aspiration biopsy procedures performed repeatedly did not increase the percentage of distant metastases, nor did it produce any demonstrable damage to the capsule of the tumor or result in implantation of the tumor along the route that the needle had traversed.

Effect of Exercise on Metabolism—Haldi and Bachmann studied the respiratory quotient as affected by exercise taken by two subjects immediately after the ingestion of 500 cc of water, 50 Gm of dextrose, 50 Gm of fructose and a mixture of 25 Gm of each of these two sugars dissolved in 500 cc of water at 37 C. The exercise consisted of performing 550 kilogrammeters of work per minute for two consecutive periods of fifteen minutes on a Prony brake bicycle ergometer. In the control experiments with water the respiratory quotient rose to approximately 0.9 during exercise, an increase of 0.1 above the base line. The increase of the respiratory quotient during exercise was practically the same when the sugars were ingested as when water alone was taken immediately before the exercise. The rise in the respiratory quotient during exercise in the experiments with water and the sugars shows that there was an increase in the relative and absolute amount of carbohydrate oxidized. The percentage of carbohydrate oxidized was not increased by the ingestion of the sugars immediately before exercise. Dextrose and fructose were equally ineffective in raising the percentage of carbohydrate oxidized during exercise. There was more carbohydrate oxidized in the second than in the first exercise period. During the first recovery period in the control experiments with water the respiratory quotient remained at practically the same level as during exercise indicating that the increase in carbohydrate metabolism induced by exercise persisted for a few minutes afterward. In the experiments with the sugars there was rise in the quotient during the first recovery period above the level reached during exercise. The greatest rise occurred in the experiments with a mixture of the sugars the least in those with dextrose. Exercise accelerated the metabolism of dextrose, whereas it had no effect on that of fructose. As the ingested dextrose did not increase the total carbohydrate oxidation during exercise it must have had a greater sparing effect than fructose on the body stores of carbohydrate.

Preoperative Study in Prostatic Hypertrophy—Shivers states that during the last three years it has been the practice at the urologic department of the Atlantic City Hospital to add to the preoperative study of the hypertrophic prostate a routine intravenous urogram and a cystoscopic grading of all prostates, taking into consideration the shortcomings of each procedure. It was found that by intravenous urography the presence or absence of renal excretion, the promptness of excretion, the degree of concentration and the presence or absence of gross changes (hydronephrosis) in the upper part of the urinary tract could be determined with a fair degree of accuracy. The author strongly advises against retrograde pyelograms in the presence of prostatic hypertrophy even when it is mechanically possible to introduce ureteral catheters, as there is always great danger of activating a latent infection in one or both kidneys. The physical examination should never be neglected even though intravenous urography is regularly practiced. In cases showing gross renal changes in the presence of a persistent pyuria, resection should be done even though all other tests are within normal limits. In every case of latent chronic infection of the upper part of the urinary tract with definite gross changes, as shown by the urogram, resection should always be preceded by a suprapubic cystostomy. A patient who will not tolerate a suprapubic cystostomy will frequently not survive a prostatic resection. At a suitable time after suprapubic drainage, resection may be carried out without endangering the patient's life. Kirwin recommends resection in cases showing marked renal impairment and other constitutional complications. The author does not agree with this recommendation if impairment of renal function is due to infection. Patients with changes in the upper part of the urinary tract, whether they are bilateral or unilateral, do much better with a two-stage prostatectomy. Urethral drainage does not seem to be adequate in these patients and, as the risk is greater, the two-stage procedure is definitely safer. A system of cystoscopic grading has been adopted which has been most helpful in selecting the type of gland best suited for resection.

Gingivitis and Oral Spirochetoses—Grove believes that oral hygiene offers the most successful weapon in diminishing the incidence of gingivitis and Vincent's angina. Surgical asepsis is indicated whenever tissues are broken, severed or bruised or the continuity of the epithelial cells is disrupted in

any manner. Pyorrhea cannot be cured or controlled by the present passive methods of approach. It has been estimated that 15 per cent of the work involves operative work by the dentist, and 85 per cent rests entirely on the oral hygiene habits of the patient. To maintain a cure in pyorrhea it would seem necessary that the patient use an alkaline mouthwash daily, one that aids in the removal of material harboring microorganisms and one that will penetrate into the subgingival and other spaces. Frequently persons who have been regularly under dental supervision present themselves for treatment of pyorrhea which has been years in developing, so that it is too late to save the teeth, owing to the involved systemic condition—such as arthritis, secondary to focal infection. The same organisms are responsible for gingivitis, pyorrhea, Vincent's infection, noma and Ludwig's angina. Mercury in the form of its insoluble salt (calomel) as a systemic spirocheticid, proper elimination of body waste material with salts, and the use of hydrogen peroxide as a local oxidizing agent offer simple agreeable and effective treatment for the diseases caused by the Vincent spirochete.

Preventing Recurrent Anorectal Fistula—Best gives three steps in the prevention of recurrent anorectal fistula: (1) the attempt to establish the internal opening definitely before operation (which is occasionally impossible even after repeated attempts), (2) the correct operative procedure with direct attack on the internal opening and (3) proper postoperative care. A fistula with its external orifice situated behind a plane passing transversely through the center of the anus usually has its internal opening in the midline posteriorly or just to one side of the midline, while a fistula with its external aperture in front of this plane generally terminates immediately opposite this external opening. The internal stoma is usually found in a diseased crypt, the margins of which are inflamed, edematous or ragged, or it may be identified by a drop of pus, a small tuft of granulation tissue, a papule, or at times merely a small injected area. The questionable region should always be examined with a small hooked probe. If no internal aperture is found and no diseased crypt exists, one must assume that the tract is not complete and excise all tissue down to the depth of the fistula. Here the discoloration of the diseased tissue by the methylene blue solution more clearly identifies any small ramifications. The existence of incomplete or blind internal fistulas is controversial, but that these actually occur at times cannot be denied. A blind fistula may develop in this region just as a blind sinus tract may occur elsewhere in the body. Before finally assuming that a fistula is a blind external type, one should make repeated attempts to locate the internal opening over a period of weeks, and, if not found, great care and ingenuity must be exercised at operation before concluding that no internal opening exists.

Paratyphoid and Related Bacteria in Cutaneous Lesions—A recent instance with fatal termination, caused by *Salmonella morganii* in association with nonhemolytic streptococci and staphylococci, led Fasting to a reexamination of several somewhat similar infections observed at the Charity Hospital since May 1936. Of the six cases reported, two patients died, a leg was amputated in one, infection of the hand with necrosis into the metacarpal bones occurred in one, a compound fracture was lanced in one, and in the remaining case there were extensive ulcerations on one leg. In one fatal case the complications were diabetes and a chronic bacillary dysentery. In the second fatal case a mixed infection followed an injury to the right knee. Marked arteriosclerosis was present in the case in which amputation of a leg was necessary. In the remaining three cases there were no obvious complicating constitutional factors. In the two fatal cases more than 1,000 cc of pus was evacuated from fluctuating masses in the thighs. In four instances the extraneous source of infection seemed evident. In one case the hematogenous route was fairly definite as the abscess formed in the thigh during the patient's stay in the hospital. In the sixth case the source remains doubtful. Cultures of the stools and urine failed to reveal these as possible sources of surface pollution. No difficulties were experienced in the isolation and culture of the bacilli in these cases. The micro organisms isolated had characteristics of the Morgan bacilli. Serologically two strains appear related to paratyphoid B and the aertrycke strains. The immunologic response to these organisms differs from common pyogenic infections. A greater interest in reporting clinical cases with similar infections will assist in a better classification and encourage the study of the immune processes involved.

*Removal of Fluoride from Water E Elvove—p 1308
A New Ocular Micrometer for Use in Dust Counting Note R T Page—p 1315

Removal of Fluoride from Water—Elvove finds that fluoride can be removed from water with the aid of tricalcium phosphate, magnesium oxide or magnesium hydroxide. As magnesium oxide appears to be the least expensive, experiments have been conducted mostly with this substance. The fluoride-containing water (5 parts per million) to be treated was introduced into tall bottles. The quantity of the magnesium oxide used corresponded to one ounce per gallon of water in each bottle. The magnesium oxide and water were then actively agitated by means of a current of air, for about half an hour. After complete settling, about three fourths of the column of water was siphoned off replaced by a fresh supply of the fluoride containing water, and the process repeated. The removal of fluoride in the first three runs was 43 to 48 parts per million. The fifth to the seventeenth runs, in the case of the calcined magnesite yielded a composite sample that showed a fluoride removal of about 21 parts per million, while in the case of the light magnesium oxide the sixth to the seventeenth runs yielded a composite water that showed a fluoride removal of about 29 parts per million. With a composite water which had received one treatment, the residual fluoride in the mixture obtained from eleven runs with a second portion of magnesium oxide was reduced to about 1 part per million or less. The fluoride-removing power of the magnesium oxides however, was not yet completely exhausted. In the subsequent twenty-five runs with the magnesium oxide that had already been used in seventeen runs there was a further removal of fluoride, corresponding to an average of about 0.8 part per million in the case of the calcined magnesite and to about 1.8 parts per million in the case of the light magnesium oxide. Different grades of commercial magnesium oxide showed different degrees of fluoride-removing power. Although a commercial light magnesium oxide was found more efficient as a fluoride remover, per given weight, than a commercial calcined magnesite, its greater efficiency was not proportional to its higher cost. In the case of the calcined magnesite particularly, since it is used extensively in building operations and for various other purposes, it may be possible to utilize the material after its availability for removing fluoride has been exhausted and thus indirectly reduce the cost of treatment.

Mental Disturbances Due to Bromide Intoxication—

Since November 1933 Cheavens and his colleagues have made a study of all cases admitted to the hospital showing evidence of toxemia. The history of previous administration of bromide, as well as the presence of stupor, confusion, hallucinations and disorientation has been considered an indication for the laboratory determination of the blood bromide content. They found significant amounts of bromide in the blood of twenty-three patients in 555 consecutive admissions. It appears that in the more severe bromide intoxications the symptoms and signs of toxic delirium predominate to a sufficient extent to permit clinical recognition in a considerable number of cases. This is not true in the milder forms of bromide intoxication. Hallucinations were present in sixteen of the seventeen patients whose blood contained more than 150 mg of bromide per hundred cubic centimeters, confusion and disorientation occurred in fifteen. Six of these patients were found to be in some degree of stupor. In the group with less than 150 mg only one patient was found with hallucinations. The remainder presented essentially the symptomatology of the underlying illness for which the bromide was administered. As the patient with a severe bromide intoxication recovers, the symptomatology tends to change, with the evidence of the underlying illness again coming into prominence. This is particularly true when the underlying illness is a protracted or severe mental disturbance. Excluding the factor of the underlying illness, the symptoms in these cases are sufficiently uniform to suggest the possibility of a bromide intoxication, and with the laboratory determination of bromide in the blood there should be little trouble in selecting these cases from any group of mental disturbances. The neurologic signs did not show the same degree of uniformity, offering little help in making the diagnosis. Defects of speech, disturbances of gait and occasional pupillary disturbances were the most prominent conditions and these were found in only a small number of cases. One of the most serious objections to the continued administration of the bromides is that, once a toxemia is established, there is great likelihood of a prolonged illness in a mental hospital. In con-

trast to intoxications with other drugs, there is little doubt that the bromide patient will be ill for a much greater period. The most frequent source of bromides in the series continues to be the physician's prescription. Since the accumulation of bromide in the body occurs at the expense of the body chloride the treatment is logically based on the administration of chloride. In addition, the administration of large amounts of water assists in the excretion of bromides as well as tending to remedy the serious state of dehydration which many patients present. The withdrawal of all sedatives seems to be the best procedure. For the determination of bromide concentration about 15 cc of blood is collected by venous puncture, allowed to clot and centrifuged. Five cc of the clear serum is removed and added to 10 cc of water in a small flask, then 3 cc of a 20 per cent solution of trichloroacetic acid is added, shaken and allowed to stand for thirty minutes. This is filtered clear. Standards are prepared by adding to 10 cc amounts of water 5 cc of standards I and II (standard I contains 100 mg of sodium bromide to 100 cc of water and standard II contains 200 mg). To each standard 36 cc of a 0.5 per cent solution of gold chloride is added and to each cubic centimeter of the filtrate 0.2 cc. is added. The standard is set at 20 and compared, 100 (or 200 if standard II is used) times the reading of the standard divided by the reading of the unknown gives the amount of bromide expressed as sodium bromide in 100 cc of serum.

- The Relation of the Hospital to Medical Education and Medical Practice as Discussed in American Medicine W B Porter Richmond —p 342

The Tobacco Heart—Golston reviews the opinions of men who have studied the physical effects of smoking and cites two cases, one of a unifocal irritation and the other multifocal in its action on the cardiac muscle. From the literature he culled the following effects on circulation, resulting from tobacco: 1 A lowered cardiac efficiency, with a diminished power of the heart to stand strain, and in some cases the excitation of premature or arrhythmic rhythm. This was demonstrated by the two case histories presented. Young adults recover quickly with the cessation of tobacco. It is conceivable that the continued use of tobacco may cause the development of an organic heart. 2 Vasoconstriction, as a contributing cause of death in organic arterial disease. Smoking is not shown to be a cause of hypertension, although the blood pressure may be temporarily slightly elevated, and thus not necessarily forbidden. Coronary sclerosis and angina pectoris are not significant except in subjects showing cutaneous reaction to nicotine free tobacco or a toxic manifestation. 3 In peripheral vascular disease, such as thrombo-angiitis obliterans, Reynaud's disease and intermittent claudication, tobacco is forbidden. With these facts in mind the author quotes Cornwall: "The tobacco heart appears to be mostly a matter of symptoms and functional disturbance, but one must not forget that a functional condition continuously abused through abnormal physiology may result in permanent structural changes. Tobacco, therefore, must be considered a toxic agent and our guiding rule must be the reactions as exhibited by our patients."

Prognosis in Rheumatoid Arthritis in Childhood T Colver—p 253

Prognosis in Rheumatoid Arthritis in Childhood—Colver presents an analysis of the prognosis of rheumatoid arthritis in sixty-nine children, two presented symptoms in the first year of life, fourteen in the third year with a maximal incidence in the preschool period between 2 and 5 years. Sixty per cent of the patients were girls. Follow-up enquiries were successful in forty-nine patients, of these, twelve are known to have died, eighteen are still active and nineteen are quiescent. The criteria of quiescence have been an absence of joint pain and tenderness for a period of not less than two years, and a blood sedimentation rate within normal limits. In no instance have symptoms recurred after a quiescent period of eighteen months. Each of the patients who died had first developed the condition when less than 5 years of age and, with one exception, each one had died within three years of the onset. The disease is thus most dangerous in the acute stages in young children. In the five fatal cases in the hospital in which a necropsy was performed there was a progressive emaciation and anemia, the patient gradually being reduced to an almost prostrate condition. In two cases there was a terminal streptococcic septicaemia (hemolytic), in one a large renal calculus and heavy urinary infection. A fourth showed advanced amyloid disease and extreme pericardial adhesions. In the fifth the necropsy revealed nothing of note apart from extreme emaciation and moderate pericardial adhesions. Pneumonia has been cited as the cause of death in most of the patients who died elsewhere. With two exceptions, of the nineteen quiescent patients every one can earn a livelihood. With one exception every patient can walk. Seven of the nineteen have completely recovered and a further four patients have recovered to all intents and purposes but full passive movement in one or two joints occasions slight discomfort. Eight old cases show some crippling, but in only two of these is the ability to earn a livelihood lost. Of the thirty-seven surviving patients in not one has the duration of activity exceeded seven years. The disease thus appears to be self limited and in a given case one feels justified in predicting the cessation of activity within a maximal period. The duration of the active phase is one of the most important factors in estimating the prognosis and apparently three years of activity is the critical period. If after three years the disease is active, the risk of a fatal outcome is negligible but the chance of complete recovery of function has almost disappeared. In the patients who recovered completely the disease ran a relatively short course, never longer than three years (twenty months was the shortest duration) and the end results also show that, when the disease was active for more than three years recovery was not complete.

Radon in Treatment of Carcinoma of Choroid—Evans describes a case of the unusual development of a metastatic carcinoma, secondary to that of the breast, in both eyes, appearing in one eye two months before its occurrence in the other. The first eye was excised, the fellow eye at that time being

normal. The second eye was treated by the application of radon seeds. In spite of evidence of further metastases the patient remains remarkably well in general condition and, although losing weight, is still active nearly five years after the original operation on the breast and still retains good vision twelve months after the incidence of choroidal metastasis in the remaining eye. The malignant condition of the eye treated by radon was confirmed in that the pathologic changes were exactly similar in appearance.

Meat Extracts as Gastric Stimulants—To establish the action of meat extracts and related substances on the gastric mucosa, Boon carried out a series of experiments on medical students. Various test meals were given to the subject on different days and the responses compared. The substances examined were beef powder, extracted beef, direct meat extract, commercial meat extract and sodium glutamate. The tests were performed on a fasting stomach. Beef powder, which represents whole meat, produces a marked secretion of hydrochloric acid over a long period. The watery extract is not so powerful, producing a secretion not much greater than that of gruel. Extracted beef is even less efficient. The most effective stimulant was the commercial meat extract. Sodium glutamate leaves the stomach so quickly that its effect on hydrochloric acid secretion is negligible. Beef powder delays the emptying time considerably as compared with gruel. Extracted beef and direct extract are not significantly different in their emptying times from that of gruel. Sodium glutamate makes the stomach empty very quickly. The extracted beef produced a very marked flow of mucus, in one case this was so great as to block the stomach tube. The secretion of pepsin is high when beef powder is administered. Of the substances examined it was the only one which stimulated the gastric mucosa to secrete pepsin. The other substances do not differ greatly from one another in their effect on secretion of pepsin, sodium glutamate being a possible exception. Following acute illnesses there is commonly a depression of gastric secretion, in such instances meat extracts, by stimulating the mucosa to an increased flow of hydrochloric acid, restore the gastric juice to normal.

- *Pulmonary Tuberculosis in Children Agnes R Macgregor and W A Alexander—p 561
Primary Thrombosis of Axillary Vein M M Cruickshank—p 597
The Swedish System of State Medicine W A D Adamson—p 603

Pulmonary Tuberculosis in Children—Macgregor and Alexander show that in 333 cases of fatal tuberculosis of all forms examined after death during the period from 1922 to 1935 the disease was found to have originated in the thorax in 60 per cent, while, when the last six years of the period are considered separately, the primary thoracic infections rise to 69 per cent. Of the 200 cases of primary thoracic tuberculosis, approximately 80 per cent terminated with meningitis and so would in most instances appear in registrars' statistics as cases of nonpulmonary tuberculosis. The true frequency of primary tuberculous infection of the lungs in childhood should be clearly recognized, for in the majority of such cases the route of infection is the respiratory tract and the source

of infection a human one, often a member of the child's family. The development of the disease in the lungs following a first infection is described in three stages (1) the "primary complex," by which is understood the original focus in the lung, and the lesions produced in the regional lymph glands secondary to it, (2) localized extensions of the disease in the lung, arising from the primary complex and (3) more widespread disseminations of disease throughout the lungs, representing the advanced and often terminal stages of the process.

*Wassermann Reaction in Maternity Work C Mackay—p 41
Ectopic Kidney A M Clark—p 45

Wassermann Reaction in Maternity Work—Mackay reports the results obtained in the routine examination of 1,000 maternity cases, in which the maternal blood and the fetal placental blood were submitted to the Wassermann reaction. Not one of the nineteen positive cases gave a history indicative of syphilis, ten patients made no complaint of any kind, two complained of varicose veins, and in the others the complaint consisted of pleuritic pain, abdominal pain, vaginal discharge and symptoms which might well be associated with cystitis and with a mild albuminuria, one gave a history of slight repeated attacks of antepartum hemorrhage. A year after the pregnancy, twelve of the total of nineteen mothers whose blood had given a positive reaction were again seen. On repetition of the test, in all instances the reaction was still positive. Nine children were alive and reported to be well, three had died. Of the twelve mothers interviewed, two had not attended the venereal clinic to which they had been directed. Data are given which are roughly in agreement with those of syphilis in the whole population and show that there has been a remarkable fall in the incidence of syphilis in maternity patients. Of the nineteen cases nine showed a positive reaction in the child. There was no instance of a positive reaction in the child and a negative reaction in the mother. In applying the Wassermann test as a routine in maternity work it is of much greater value to submit the maternal blood to the test than the fetal (placental) blood.

Surgical Treatment of Nonparalytic Squint—Kirwan states that in Bengal extreme degrees of concomitant squint, both convergent and divergent, are very common. The convergent varieties can always be cured and in the case of divergent ones excellent results can be obtained provided the vision is good in each eye. In eleven of the twelve cases that he records he obtained good results by a single operation on the muscle of one eye. The more usual types of surgical treatment carried out in the eye infirmary consist of (1) resection with advancement combined with recession of the opposing muscle, (2) resection with advancement combined with partial tenotomy and (3) simple advancement or simple recession in moderate degrees of squint.

Stable Solution of Antimony for Treatment of Kala-Azar—Napier and his associates have used a pentavalent compound of antimony, containing 20 mg of antimony (metal) in 1 cc. of solution, in the treatment of ten cases of kala-azar. These were all Indian males. The diagnosis was made in every case by the finding of the parasite, usually by spleen puncture but in one case by liver puncture. The cases were not selected, except that one patient with pneumonia and kala-azar and another with pulmonary tuberculosis and kala-azar

were excluded, otherwise, consecutive previously untreated persons admitted to the Indian male wards were treated with this drug. All the injections were given intramuscularly. The total amount of antimony given varied from 0.96 to 1.74 Gm., administered in from eight to ten injections (daily or on alternate days). In no case did a high fever continue for more than nine days. The spleen was markedly reduced and in no case was it more than 2 inches below the costal margin at the time of discharge. The weight increased during the patients' stay in the hospital and subsequent to the commencement of treatment the average increase was 5 pounds (2.2 Kg). Only one patient complained of any pain after the injection and in his case the pain lasted only an hour or so. No abscess formation or local induration was noted in any case.

The Precancerous Cervix—Strachan bases his remarks on the clinical and histologic investigation of several hundred cervixes removed during the last ten years, mainly for chronic inflammatory lesions. In a small proportion of these cases early carcinoma was unexpectedly found, while the examination of a further 400 cases of frank cervical carcinoma has been of corroborative value. Leukoplakia of the vulva is generally regarded as precancerous in that epithelioma supervenes in a large proportion of such cases if left untreated. The main clinical precancerous cervical lesion is produced by the various effects of chronic infection usually secondary to obstetric trauma. It is common knowledge that with a hypertrophied, everted and eroded cervix many annoying gynecologic symptoms may occur but that carcinoma may not develop, while in a cervix with quite a small eroded area and in about 5 per cent of cases in such an area apart from obstetric trauma, carcinoma may occur. Leukoplakia of the cervix has the same relation to cancer formation as leukoplakia of the vulva or tongue. The main lesion of connective tissue which would appear to predispose to the formation of carcinoma in the cervix is subepithelial hyaline degeneration, and this is seen only in old standing cases. A suggestive feature is a separated clump of surface epithelial cells in the connective tissue. There are several others. One of the most important of these is the type of interpapillary epithelial downgrowths. The main precancerous signs are those of overactivity of the cell columns or of the individual cells, and this is not indicated by mere multiplication of layers which is often seen in procidentia in which carcinoma is rare. The main change that the author has been able to observe which might be regarded as precancerous is a tendency for the cervical glands to lose their racemose appearance and to revert to a simpler tubular type. This would represent a degree of metaplasia of the gland as a whole and not necessarily of the epithelium lining it. The main changes that would indicate a tendency toward carcinoma formation are to be found in slight variations in the normal structure or relations of a limited

number of cells, if such variations are marked and if the condition of metaplasia so produced involves a large proportion of the epithelial cells, a condition of early carcinoma is present. Very careful examination is thus called for, often of several sections of a particular specimen, in estimating the presence of such precancerous changes, and the first thing to be noted is the general appearance of the constituent cells. In the nonmalignant squamous epithelial cell the cytoplasm is evenly stained, but in a carcinomatous cell the stain is absorbed quite unevenly, producing a mottled appearance, and this condition is widespread in an area of carcinoma. Inequality of staining indicates a tendency to the formation of carcinoma. If mitotic figures are seen in a number of cells, it indicates the actual presence of carcinoma, if the process is limited to a cell or two with surrounding and intervening normal cells, it would indicate a precarcinomatous disposition. Actual penetration of the basement membrane is a definite sign of malignant manifestation. It is emphasized that a feature of precancerous changes is that they are limited to a few isolated cells, and it is further emphasized that in a particular cell the changes should be few. Thus, if a cell shows nuclear mitosis, hyperchromatism and increased relative and absolute size of the nucleus and nucleolus, the probability is that it is already carcinomatous, and further search will probably confirm this by demonstrating similar changes in adjacent cells. If one can identify cervical cellular changes which are not yet carcinomatous but are likely to proceed in that direction, a minor operation, such as amputation of the cervix, would save the patient from the terrors of carcinoma and thus represent prophylactic gynecology in the best sense.

Extroversion of Ovaries for Functional Amenorrhea—Bailey performed extroversion of the ovaries in seventeen cases of secondary or functional amenorrhea, to which has been added a minor degree of endocrine therapy. The most potent extract used in this respect has been the anterior pituitary-like gonadotropic principle, small doses (about six injections of 200 rat units) of which have been given in some cases. Thirteen patients showed a successful result by the establishment of regular menstruation immediately following operation. There were four failures. There were three patients who were treated by modern endocrine therapy, as advocated by Kaufmann, prior to operation with no result. While recognizing the inadvisability of subjecting young women suffering from developmental relative or secondary amenorrhea to laparotomy without a thorough trial of treatment along general and endocrine lines, the author believes that the operation of extroversion of the ovaries is justifiable in the following cases: 1 When endocrine therapy alone fails to restore regular menstruation or something approaching this state. 2 When a multicystic change of the ovaries can be detected clinically and the progressive nature of the lesion renders the outlook less and less favorable. 3 When time itself fails to rectify menstrual function and particularly when it becomes worse as time goes on. 4 When the nervous system shows signs of derogatory disorder in consequence of the fact of amenorrhea.

Virus in Etiology of Rheumatic Diseases—Eagles and his associates prepared suspensions of particles bearing a close resemblance to elementary bodies of known virus infections from a variety of materials from patients with acute rheumatic fever, rheumatoid arthritis and chorea. Nonrheumatic suspensions bear a close resemblance to those obtained from true rheumatic sources and to undisputed virus elementary bodies of comparable size. Pericardial, pleural and joint exudates contain the particles of uniform size and density to a much greater degree than other materials from acute rheumatism and rheumatoid arthritis or from nonrheumatic materials. Since these particles are not confined to rheumatic infection, agglutination tests have been used to test for their relation to rheumatism. The suspensions obtained from pleural, pericardial and joint exudates are specifically agglutinated, thus lending support to the observation that the preponderance of particles of regular size and density observed in these may be true virus bodies. In only one instance was a suspension from synovial membrane from rheumatoid arthritis specifically agglutinated. Fibrin from acute pericarditis, on the other hand, yielded suspensions that were specifically agglutinated probably by reason of the exudate present. The control suspensions, which were selected to cover a wide range, were in no case agglutinated by any of the known positive serums. When the agglutination results are studied, it is clear that not only are suitable suspensions from acute rheumatic fever, rheumatoid arthritis and chorea agglutinated by the serums of patients suffering from the particular disease from which the suspension was prepared but also considerable cross agglutination appears within the group of rheumatic diseases. From these results it would seem that these diseases are closely related. While it cannot be said that their etiology is identical, it is at least probable that they possess some common significant factor which is reflected in serologic tests. The conception of rheumatic fever and rheumatoid arthritis as closely related diseases is supported by other investigators. The common factor need not be of etiologic significance but may be some nonspecific cause such as pyrexia or an increased erythrocyte sedimentation rate. The series of cases examined is sufficiently comprehensive to show that the agglutination titer does not run parallel with either of these factors. Increased erythrocyte sedimentation is not responsible for the agglutination. Until these suspensions are proved to be infective, the possible nature of the reaction must be considered particularly in the light of certain serologic observations made in other diseases. In view of a virus hypothesis for rheumatism, the possibility of a reaction between the patient's own serum and exudates was considered, particularly in the light of the observations of Hughes (1933) on yellow fever. Dilutions of serum from a patient gravely ill with rheumatic fever in the acute stage were set up in hanging drops with his own pleural exudate after it had been centrifugated for one hour at 14,000 revolutions per minute. As a result of this centrifugation a suspension of typical rheumatic bodies had been obtained which was specifically agglutinated by the patient's own serum as well as by other acute rheumatic serums which showed at the same time definite agglutination with other acute rheumatic suspensions. The hanging drop preparations of serum dilutions and supernatant portion of the pleural exudate remained perfectly clear when examined microscopically over five successive days. No trace of precipitation was found with other known positive serums and this pleural exudate.

Cause and Prevention of Sulfhemoglobinemia—Archer and Discombe believe that any treatment which helps the formation of a liquid stool may be expected to accelerate the formation

of sulfhemoglobinemia. The intracorpuseular sulfhemoglobinemia, associated with the administration of drugs derived from aniline, results from the combination of hemoglobin with the hydrogen sulfide absorbed from the intestinal tract, this reaction is catalyzed by the drug circulating in the blood. The normal absorption of protein digestion products in the small intestine is diminished by purgation, causing increased putrefaction in the colon and a production of hydrogen sulfide much in excess of normal. Saline cathartics are most active in this process because their osmotic action maintains the contents of the colon in a semifluid state, thus accelerating putrefaction. The development of sulfhemoglobinemia can be prevented or considerably delayed by keeping the colon free from food residues by (1) cleansing the colon with enemas before treatment is started, if purgatives have been given previously, (2) giving the patient a low residue diet, of adequate caloric value, containing few eggs, and (3) giving large, regular doses of liquid petrolatum. In treatment with sulfanilamide, it is important to examine spectroscopically the blood of all patients who develop cyanosis, for occasionally the cyanosis is due not to the presence of abnormal pigments in the blood but to the development of some other organic disease, such as pneumonia.

A New Fever Entity—In August 1935 the occurrence of a number of cases of fever among workers in a large meat-works in Brisbane was brought to the notice of the health director, who directed Derrick to investigate the matter. It appeared that the cases which incited the inquiry had begun to occur early in 1933. The fever continued for from seven to twenty-four days. The most striking feature was the uniform failure of blood cultures and agglutination tests to throw light on the diagnosis. Typhus, undulant fever, aberrant typhoid, paratyphoid and leptospirosis have been ruled out by negative results to tests. Guinea-pigs acquired the disease readily by injection of blood or urine from a patient. Their subsequent immunity has rendered it possible to prove that this (Q fever) is a pathologic and a clinical entity. As no organism could be seen in or cultivated from human or guinea-pig material, it appeared likely that the infecting agent was a virus. Infected guinea-pig liver was sent to Burnet of Melbourne, who, transferring the infection to mice, was successful in discovering Rickettsia bodies in their spleens. Cases of fever of doubtful cause were found to occur from time to time in and around Brisbane apart from meat workers. When these were investigated, some of them proved to be due to Q fever. The nine cases described include five from the abattoir, two from other parts of Brisbane, one from Gympie and one from Pomona. In case 6 the incubation period could be deduced as fifteen days or less. The onset of the illness in all cases was acute. Within a few days of the first premonitory symptoms the victims were in bed quite ill. The first complaints were usually malaise, anorexia, headache, pains in the back and limbs and feverishness. As the illness developed, the symptoms became more severe and the general condition of the patient worse. The headache was troublesome and persistent and often interfered with sleep. The face was flushed or pale, the eyes were closed and the tongue was coated. In the more severe infections the patient became drowsy, even stuporous, and passed on into a typhoid state. The symptoms gradually abated as the temperature fell. With patients having the shorter course the improvement, once it started, was rapid. None of the cases have been fatal. The epidemiology is obscure. There is no obvious

relation to the season. It is suspected that there may be a reservoir of infection in some animal with a blood sucking parasite as a vector, but attempts to find such a reservoir have failed.

Phrenic Paralysis and Thoracic Complications in Subdiaphragmatic Infection—Coope and Reid point out that the earliest manifestation of thoracic complications of a subphrenic infection is usually a plastic pleuritis. In this way the undersurface of the lower lobe of the lung is fixed to the diaphragm. If the infection is more intense, especially if it affects a wide area under the diaphragm, there may be a rapid spread through the lymphatic glands to a considerable area of the pleura, with the development of a pleuritic effusion. An empyema may thus form and remain localized and encysted. After surgical drainage of a subphrenic abscess, fibrinous adhesions formed in the thorax may be broken down when the diaphragm descends again to its normal position. If the empyema is encysted in plastic pleuritic exudate, the infection may invade the lung and produce either pneumonitis or abscess of the lung, the pus may find its way into a bronchus, when it may be coughed up. In cases of long standing there may be actual necrosis of diaphragmatic tissue, with perforation of the diaphragm, and an hour glass type of abscess above and below the diaphragm. Effective treatment will therefore involve a careful estimate of the pathologic picture—of what has happened during the stage of active inflammation and also what is likely to happen as the result of the processes of recovery and repair. A case is reported in which the crippling effect of scarring following a subphrenic inflammation was dealt with by crushing the phrenic nerve and so paralyzing one half of the diaphragm.

Continuous Murmur of Superior Vena Cava—Lian states that the continuous murmurs that are perceptible at the neck have been known since the description of Laennec, their origin in the jugular vein had been established by Hope and particularly by Aran. In this report he discusses continuous murmurs of the superior vena cava. After reporting three cases he describes the characteristics of the murmur, its etiology and mechanism and the differential diagnosis. He shows that it is a continuous murmur with systolic reinforcement, the main focus of which is located in the second and third intercostal spaces, two or three fingerbreadths away from the right side of the sternum. Its intensity is great. Its timbre is generally sharp, occasionally soft but rarely musical. The intensity and the timbre may vary in the course of the development. The author mentions five factors which he thinks prove that the curious murmur originates in the superior vena cava: (1) the continuous character analogous to the murmurs of the jugular vein, (2) the maximal localization in the region of the projection of the superior vena cava, (3) the considerable propagation in the right side of the thorax, the weak propagation in the left side of the thorax and the minimal and inconstant propagation in the neck, (4) the fact that this peculiar murmur is encountered in three cases, two of which presented signs of compression of the superior vena cava and (5) the disappearance of the murmur in a case in which the disappearance coincided with a period of amelioration of the signs of compression of the superior vena cava. Discussing the etiology and the mechanism of the murmur, the author points out that it is encountered chiefly in syphilitic patients who have an aortitis with mediastinitis or aneurysm compressing the superior vena cava. In the differential diagnosis of the continuous murmur of the superior vena cava, the author mentions the continuous murmurs due to persistence of the arterial canal, to the communication between the aorta and the superior vena cava, to propagation from the arteriovenous aneurysms of the members, to propagation of the continuous hyperthyroid murmur and to cirrhosis of Curvillier-Baumgarten. He mentions the continuous murmur of the interscapulo-vertebral space, which he describes in the subsequent report.

Continuous Venous Murmurs of Right Interscapulo-vertebral Space—Lian describes a continuous venous murmur of the right interscapulo-vertebral space in two cases. In the first case there exists a small hydatid cyst in the immediate neighborhood of the continuous murmur. It is therefore plausible to admit that the murmur is due to the compression of a branch of the posterior pulmonary vein arising from the right hilus. In the second case there exists a small abnormal shadow in contact with the origin of the right bronchus. There is justification for thinking that it results in a compression of the pulmonary vein, perhaps by a tracheobronchial adenopathy. Several intracutaneous tests with tuberculin were negative. The author concludes that these two observations together with the three observations of the preceding report about the continuous murmur of the superior vena cava show that there exist thoracic continuous venous murmurs which are distinct from the single analogous thoracic murmur already known, the continuous murmur of the persistence of the arterial canal.

*Paralysis of Dental Origin Attempt at Explanation of Peripheral Facial Paralysis Improperly Called A Frigore Two Cases P Panneton—p 1356
Epidemiologic Importance of Cutaneous Reactions with Tuberculin in Adults R L Dehenedetti and E Balgaries—p 1359

Destruction of Micro-Organisms in Drinking Water by Means of Tartaric Acid—Violle found that the bacillus of typhoid (Eberth type) is killed after a contact of from twenty to thirty minutes with a 0.35 per cent solution of tartaric acid, that the bacillus of dysentery (Shiga type) is killed after a contact of two hours with the same solution and that the bacillus of cholera (agglutinable vibrio of Koch) is killed after a contact of ten minutes with the 0.35 per cent or even a 0.25 per cent solution of tartaric acid. Thus a contact of two hours' duration with the tartaric acid solution will destroy all bacilli that are the cause of the three serious infectious diseases of the intestinal tract. It is simple to overcome the acid taste of the drinking water to which tartaric acid has been added. Neutralization is readily effected by adding approximately the same amount of sodium bicarbonate (3.5 Gm.). The author thinks that this method of treating drinking water with tartaric acid will be helpful in checking typhoid, bacterial dysentery and cholera.

Peripheral Facial Paralysis—Panneton observed two cases of facial paralysis of the peripheral type, which developed after dental extractions. One of the extracted teeth was an upper and the other a lower premolar. The author investigated how the extraction of a tooth may lead to facial paralysis, that is, what relation exists between the facial nerve in its passage through the fallopian aqueduct and the upper and lower premolar regions of the same side. He investigated four possible connections: by contact, by vascular channels, by lymphatic channels and by nervous channels. After ruling out the connections by direct contact and by the vascular and lymphatic passages, he studied the nervous connections. He reaches the following conclusions: 1. In cases of facial paralysis of dental origin, the point of transmission is found at the level of the two superficial petrosal nerves, the large and the small, both of which enter the geniculate ganglion in contact with the facial nerve. 2. A large number and perhaps the majority of facial paralyses of the peripheral type, which are generally referred to as "a frigore," are of sympathetic origin. 3. These forms of paralysis are dependent on deep facial lesions. 4. The peripheral facial paralyses are most of the time, if not always, the result of circulatory disturbances in the vasa nervorum of the seventh cranial nerve, particularly in the region of the geniculate ganglion, and thus as a result of a physiologic lesion of the cephalic sympathetic.

Critical Remarks on Hereditary Syphilis M Perrault—p 1349

Radial Pulse in Blood Transfusion—Fourrestier points out that in a previous report (see also THE JOURNAL, September 11, p 913), he discussed the importance of the slackening of the radial pulse during and after blood transfusions that are given in case of hemorrhages. In this paper he discusses the importance of the radial pulse in blood transfusions that are considered as true "hemotherapy", that is, those transfusions which are given without the urgency of hemorrhage. In this type of transfusion the radial pulse must remain practically unchanged from the beginning to the end of the intervention or, after a temporary acceleration, it must revert to the initial rhythm ten minutes after the end of the transfusion. In some cases a mild slackening of the radial pulse may even be observed. This is always a favorable sign and indicates that the transfusion is well tolerated. However, if there is a permanent acceleration of the pulse it may be caused by an imperfect technique of transfusion, or the transfusion may have been too abundant. In certain anemic patients it is necessary to avoid quantities in excess of 200 cc. In these patients it is better to repeat the transfusions than to inject one large quantity of

blood In case a reaction of intolerance is feared, the only efficacious treatment should be resorted to, namely, the injection of morphine, which, if there is the least doubt about the patient's susceptibility for such a reaction, should be given as a prophylactic before the transfusion

Virulent Antigen of Eberthella Typhi—Aichelburg and Montagnini studied thirty-five strains of Eberthella typhi isolated from the feces or the blood of patients suffering from typhoid The group included recently isolated and old strains Researches were also made on twenty-eight specimens of blood serum of the patients Thirty-four strains, in the group of thirty-five, contained the Felix-Pitt "V_i" (virulent) antigen Thirty strains were agglutinated by blood serum which contained the specific O antibody Twenty-nine strains of this group and four of the five which were not agglutinated by the O antibody were agglutinated by blood serum containing the V_i antibody In the majority of the blood serums the agglutinating titer of V_i and O antibodies was high Intraperitoneal inoculation of suspensions containing any of the twenty-nine V_i strains to guinea-pigs killed the animals In twenty-five out of a group of twenty-eight specimens of blood serum of patients suffering from typhoid or of convalescents the content of V_i antibodies was low A relation between the presence and amount of V_i antibodies in the blood serum of the patients and the clinical evolution of the disease cannot be established The antigen-antibody reaction between strains of Eberthella typhi and the O antibody takes place but is invisible It is possible to have agglutination, however, by using a large amount of O antibody The variations S-R (smooth-rough) of typhoid bacilli induce no changes in the agglutinability of the bacilli by V_i antibodies The V_i antigen lasts for years in the strains of Eberthella typhi which are preserved on common cultural mediums The strains of Eberthella typhi which contain V_i antigen are extremely sensitive to the action of antityphoid bacteriophage The authors say that some of their results conflict with those reported in the literature, especially by Felix, Pitt and Kauffmann According to the authors there is no relation between the presence of V_i antigen in Eberthella typhi and the lack of agglutination of the organism by O specific antibodies The existence of reversible gradual transformations of Eberthella typhi into strains having and losing, respectively, V_i antigen and agglutinating properties for O antibody has not been proved Old age has no influence on the agglutinating properties of V_i antigen, provided Eberthella typhi is preserved in simple cultural mediums Most of the strains that contain V_i antigen are virulent to white rats Their virulence to man has not as yet been established V_i antigen does not prevent

binding between O antigen and O antibody The authors conclude that the chapter of serology of Eberthella typhi is waiting for researches, especially because of the importance of V_i antigen in immunization against typhoid

*Sedimentation Speed of Erythrocytes in Intestinal Amebiasis A V Cicchitto and E Cicchitto—p 274

Sedimentation Speed of Erythrocytes in Amebiasis—According to the Cicchittos, in intestinal amebiasis in tropical countries the sedimentation speed of the erythrocytes is slightly increased There is a parallelism between the behavior of the sedimentation speed and the clinical symptoms The most rapid sedimentation speed is in the blood of patients suffering from enlargement of the liver and liver disorders The changes of the sedimentation speed of erythrocytes are due to disturbances of the metabolism of water and sodium chloride, which are induced by diarrhea, to changes in the metabolism of calcium and to alterations in the crasis of the blood Intestinal toxemia, displacement of labile proteins of the blood and the dysfunction of the liver and of the reticulo endothelial system are also increasing factors of importance Administration of a specific treatment improves the crasis of the blood and the general condition of the patient and simultaneously brings the sedimentation speed to normal The sedimentation speed in intestinal amebiasis has no diagnostic value It has a prognostic value, as it shows the evolution of the condition By evaluating the behavior of the velocity of sedimentation during administration of treatment, one is able to determine the intensity and duration of the treatment needed

*Splenopathies in Association with Gastroduodenal Diseases M Velterra—p 267

Intravenous Vaccine Therapy of Brucellosis C Pegoraro—p 270

Splenomegaly and Gastroduodenal Diseases—Velterra reports seven cases of chronic splenomegaly of the congestive fibrous or thrombophlebitic type which was associated with gastroduodenal diseases According to the author, the condition is more frequent in men than in women The enlargement of the spleen follows a chronic course before the gastroduodenal symptoms appear Frequently a transient attack of malaria

takes place early in the course of the disease of the spleen. The clinical and roentgenologic aspects of the gastroduodenal symptoms are varied, showing ulcer, duodenitis, pseudoduodenitis, erosions of the gastric and duodenal mucosae or simple congestion of the gastroduodenal mucosa with a tendency to grave hematemesis and intestinal hemorrhage. The tendency to hemorrhages appears late in the evolution of the disease of the spleen. According to the author, disturbances of the abdominal, especially the portal, circulation are the cause of the disease of the spleen with consequent alterations of the gastroduodenal mucosa, which may vary from simple congestion and erosion of the mucosae to formation of ulcer.

*Observations on Poliomyelitis in Years from 1931 to 1936 A Stender—p 1209
New Simple Colorimetric Procedure for Examination of Function of Sweat Glands L Guttman—p 1212

Observations on Poliomyelitis—According to Stender, it is well known that epidemics change in the course of centuries or even of decades. This is especially true of poliomyelitis, which occurred only sporadically until the beginning of this century but has appeared more frequently in epidemics in the temperate zones during the last four or five decades. In the author's province (Silesia) epidemics were observed in 1932, 1935 and 1936. Diagrams indicating the number of cases and their distribution in the different months of the years from 1931 to 1936 inclusive reveal that epidemics are usually preceded by a series of sporadic cases. Although the epidemics usually cease with the onset of cold weather, they may extend beyond the so called typical months into the winter months. The initial symptoms are frequently like those of influenza, but within a few hours, or one or two days, they are followed by the symptoms of the preparalytic stage, which has been designed as the meningeal period because the symptoms are those of a histologically proved infiltration of the meninges, particularly the pia mater. In the fifty-one cases of poliomyelitis observed by the author, the following preparalytic symptoms were observed: rigidity and pain of the neck (eleven times), pain in the back and lumbago (seven times), pains in the joints (nine times), hypersensitivity to tactile irritation of the skin (twice), profuse sweating (six times), disturbances of the bladder (four times), paresthesias in fingers and toes (once), gastric and intestinal disorders (eight times), abdominal pains (seven times), pharyngitis (nine times). Whereas some of these symptoms are characteristic for poliomyelitis, others might suggest other infections and so it may be impossible to make the definite diagnosis of poliomyelitis on the basis of the preparalytic symptoms. However, if poliomyelitis is suspected, a lumbar puncture should be made for the purpose of examining the cerebrospinal fluid for pleocytosis may exist, during the preparalytic stage. To be sure, leukocytosis of the spinal fluid is found also during the incipient stage of epidemic meningitis, which, however, occurs chiefly during the spring and disappears with the onset of warm weather. Other forms of meningitis are usually readily differentiable from the preparalytic stage of poliomyelitis because the protein values are generally greatly increased which is not the case in poliomyelitis. The paralysis does not always spread to adjoining muscle groups but may first attack a leg, then an arm, then the musculature of the trunk and after that the other extremities. In view of this mode of spreading it has been suggested that from the blood or lymph channels the virus reaches the spinal cord successively at various sites. The ascending type of paralysis was observed twice by the author and in both cases death was caused by respiratory paralysis. Convalescent serum should be administered during the preparalytic stage and even during the paralytic stage. The author injects the serum both into the lumbar portion of the spinal cord and into the muscle and obtained favorable results.

*Simple Reaction for Demonstration of Bilirubin in Urine B von Purjesz—p 1271

The Jaw Winking Phenomenon—Ascher says that Gunn in 1883 gave the first description of the jaw winking phenomenon, and about 100 cases have since been reported. His case reported here presents some unusual aspects and throws light on the origin of the phenomenon. A man, aged 44, had syphilis, complete oculomotor paralysis on the right side, loss of the pupillary reflexes on both sides and bilateral paralysis of the accommodation. The patient was subjected to intensive treatment with bismuth compounds and neoarsphenamine and to malarial therapy. After the completion of these treatments the patient observed one day that when he opened the mouth and chewed, the formerly entirely immobile upper lid jerked upward. After about a week this phenomenon ceased and the upper lid could be moved voluntarily. Meanwhile the other signs of paralysis persisted. The author points out that the majority of cases of jaw winking (jaw lid phenomenon) are associated with congenital ptosis. The intravital development of the jaw lid phenomenon is rare, but what is even more unusual is the fact that it appeared and disappeared in a short time, a peculiarity which never before has been reported. The author points out that the temporary character of the phenomenon contradicts the theory that it is the result of abnormal connections between the nuclei in which originate the involved nerve fibers. The author is inclined to accept as an explanation the existence of innervation complexes which are atavistic and dormant under normal conditions but which become active in case of disturbances in the oculomotor region. He calls attention to other manifestations that suggest a connection between the lifting of the lids and the opening of the mouth (opening of the eyes during eating and opening of the mouth while looking sharply).

Simple Demonstration of Bilirubin—It is pointed out by von Purjesz that the demonstration of bilirubin in the urine is based on the oxidation of bilirubin to biliverdin. The reaction suggested by him is based on this oxidation. From 2 to 3 cc of urine is placed in a test tube and is mixed with 2 cc of a 20 per cent solution of sulfosalicylic acid. Then from two to five drops of a 30 per cent solution of hydrogen peroxide is added. After shaking, the mixture is left standing, the green coloration appears after a few minutes or, at the latest, after fifteen minutes. The intensity of the green depends on the quantity of the bilirubin; if the bilirubin content is slight, there appears an olive green instead of a grassy green. If the urine is free from bilirubin, a reddish color develops. The presence of considerable quantities of blood impairs the reactions, but this shortcoming can be overcome by filtration. Moreover, it is possible to use other types of acid, but the author suggested sulfosalicylic acid because it is available in the smallest laboratory. He stresses that the method is simple, reliable and sensitive and can therefore be used by the general practitioner.

- *Toxic Effects of Arsenic Treatment Siemens and Simons—p 1444
Newer Results in Sphere of Bechterew's Disease L Grabowski—p 1446
*Unusual Form of Vascular Impairment in Scarlet Fever H Zischinsky—p 1448
Question of Treatment of Dazed Condition in Epilepsy F Baldauf—p 1456
Residual Conditions After Cholecystectomy and Their Treatment with Hormone of Wall of Gallbladder R Bimler—p 1458

Toxic Effects of Arsenic Treatment—Siemens and Simons point out that there are widely differing opinions about the toxic effects of the doses of arsenic applied in dermatologic disorders. Moreover the estimation of the incidence of toxic

complications is difficult, because there is no uniformity in the dosage. The authors describe observations in 137 cases of psoriasis in which arsenic treatment according to Gebert was employed for periods of from two to six months. The Gebert treatment was given in the strong dose (fifty-seven cases) or in the weak dose (eighty cases). Gebert's treatment consists in the administration of arsenic in the form of pills (Asiatic pills) and of drops. In the strong treatment pills of 0.005 Gm are given, in the weak treatment pills of 0.001 Gm. All the patients treated by the authors showed toxic manifestations. The maximal dose could be reached only in some of the patients and only a few could support the maximal dose for longer periods. Habituation to arsenic was obtained in a few cases, in others, hypersensitivity developed instead. Abrupt cessation of the arsenic medication never resulted in undesirable manifestations, and it is therefore unnecessary to decrease the number of drops gradually. Since pepper, which is generally added to the Asiatic pills, may cause undesirable complications, it should be omitted. The authors observed also that arsenic treatment does not, as is often stated, result in an increase in weight, but rather in a decrease. Their patients had an average loss of weight of 5 Kg. Cutaneous manifestations were frequently observed in the course of the treatment with arsenic. More than a third of the patients developed melanoses. These signs of intoxication were surprisingly more frequent in the weaker form of arsenotherapy than in the stronger form. Arsenical zoster was observed in thirteen cases of the group in which the weak treatment was administered and in only one of the patients receiving the stronger doses. The zoster disappears again, even if the arsenotherapy is continued, consequently it is no contraindication to the continuation of the treatment.

Unusual Form of Vascular Impairment in Scarlet Fever—Zischinsky recently reported three cases of non-nephritic edema after scarlet fever. In one of the patients, cutaneous hemorrhages developed and, on the basis of this case, the disorder was considered to be a form of vascular impairment. The present report about this relatively rare complication of scarlet fever was occasioned by the observation of another case and by the fact that the author's attention had been called to earlier reports on this condition. It had been pointed out to him that Quincke as early as 1882 described simple dropsy in scarlet fever and in 1906 the same author described observations on toxic dropsy in scarlet fever. Zischinsky thinks that his observations and those reported by Quincke are identical, although Quincke fails to mention cutaneous hemorrhages. After reviewing other reports from the earlier literature of dropsy after scarlet fever, the author suggests that the absence of reports about this form of vascular changes from the recent literature does not mean that such cases did not occur but rather that they were overlooked or incorrectly interpreted.

*Vitamins in Auxiliary Treatment of Chronic Articular Diseases E. Maliwa—p. 996

Vitamins in Chronic Articular Disorders—Maliwa takes up cases of chronic arthritis in which roentgenoscopy discloses a diffuse deficiency in calcium with relatively slight changes in the joints. This calcium deficiency is not manifested by the lacunar outlines characteristic for acute atrophy of the bones, its x-ray appearance being that of the atrophy of inactivity. Clinical examination reveals a diffuse sensitivity to pressure in the involved bone. In such cases medication with vitamin D is a valuable therapeutic adjuvant, in addition to the usual measures. The author recommends the administration of vitamin D in the form of drops, given two or three times daily, for a period of six weeks. After an interval of four weeks, the same medication may be repeated. The second group of cases discussed by the author are those of typical infectious arthritis. He shows that in this disorder medication with vitamin C is helpful. He provides vitamin C in the form of tablets and in the diet. If calcium deficiency develops in cases of chronic infectious arthritis, the combined administration of

vitamin C and D is advisable. The third group of cases are those in which arthritic and neuritic symptoms concur. In some of these the symptoms of the joints are comparatively slight but the pains are usually severe. In such cases the administration of vitamin B₁ is helpful.

*Meningism in Leukemia and in Weil's Disease J. E. Minkenhof—p. 4448

Treatment of Addiction to Alcohol A. M. Meerloo—p. 4456

Food Poisoning by Staphylococci—Timmerman describes several cases of food poisoning that developed after the eating of liver sausage. Examination of the sausage revealed the presence of staphylococci, which proved capable of forming enterotoxins. Since experiments on animals are not conclusive in determining that food poisoning is caused by staphylococci, a test was made on a person who volunteered. The person developed symptoms of acute food poisoning. The author thinks that a larger number of cases of food poisoning are caused by staphylococci than is generally believed and that poisonings that develop after the eating of cheese are often caused by staphylococci. To be sure, poisoning by cheese has been ascribed to *Bacillus coli*, but studies of many samples of cheese revealed that *Bacillus coli* was present in almost 60 per cent of the samples, but none of these samples produced poisoning when consumed. Thus the causal significance of *Bacillus coli* for cheese poisoning seems to be disproved.

Meningism in Leukemia and in Weil's Disease—Minkenhof reports several cases that presented symptoms of severe meningism. The first patient had a subacute lymphatic leukemia which presented the aspects of a meningococcal sepsis with meningitis. The author points out that neurologic changes are occasionally observed in patients with leukemia and he reviews the literature on neurologic changes in leukemias. The other patients had Weil's disease. In these patients the only symptoms were pyrexia and meningeal irritation. The author shows that in patients with Weil's disease there is no direct relationship between the degree of meningism, the composition of the cerebrospinal fluid and the possible occurrence of *Leptospira* in the arachnoid space. Several other authors have made the same observation, namely, that in all forms of Weil's disease the spinal fluid may be normal as well as abnormal. Apparently it is often possible to detect *Leptospira* in the spinal fluid during the first week of Weil's disease. The author emphasizes that in all cases of meningism and serous meningitis in which the cause is obscure the possibility of infection with *Leptospira* should be taken into consideration.

Hyperthyroidism and Exophthalmic Goiter—Krogh and Okkels state that the metabolism and histologic examinations show that simple hyperthyroidism in guinea pigs (hyperthyroidism induced by administration of thyroid preparations) is not affected by iodine either in inorganic preparations or in the form of 3,5 diodo-4-oxyphenylalanine. Experimental exophthalmic goiter (hyperthyroidism caused by injection of a preparation of the thyroid-stimulating hormone) is acted on by iodine, both in inorganic combinations and in the form of 3,5 diodo-4-oxyphenylalanine and when the doses are equal more rapidly by potassium iodide and slowly by 3,5 diodo-4-oxyphenylalanine. The administration of iodine alone, like the administration of thyroxine, to some degree reduces the function of the thyroid; iodine cannot further reduce the function of a gland acted on by thyroxine.

THE PATHOLOGIC PHYSIOLOGY OF THE COMMON BILE DUCT

ITS RELATION TO BILIARY COLIC

WALTMAN WALTERS M.D.

WINFIELD L. BUTSCH M.D.

AND

PAUL A. KNEPPER M.D.

ROCHESTER MINN.

In the past three years we have been aided in our studies of the pathologic physiology of the biliary tract associated with surgical lesions by being able to visualize the common and hepatic ducts under the fluoroscope and by roentgenographic studies after injection into the common duct through a T tube of nonirritating substances which are opaque to roentgen rays¹. Briefly stated, the cholelithograms so obtained will reveal the presence of (1) any narrowing of the common bile duct and persisting pancreatitis, with an abnormally patent duct of Wirsung, (2) an overlooked stone in the common bile duct, (3) spasm or stenosis of the sphincter of Oddi, and (4) carcinoma of the ampulla of Vater or of the head of the pancreas.

In an effort to determine the influence of the sphincter of Oddi in this respect, studies of the pressure within the common duct were carried out in a series of surgical cases in which the common duct had been explored and drained by T tube¹. With spontaneous attacks of pain similar to that described as biliary colic, increase in intraductal pressure occurred. In some cases injections of morphine produced similar effects, and, when roentgenographic studies were made, spasm of the lower end of the common duct was noted and marked filling of the intrahepatic ducts with the opaque substance used to measure intraductal pressure (brominol) was visualized. Recognizing that this afforded an ideal opportunity for physiologic and pharmacologic studies of the sphincter of Oddi in human subjects, the action of various drugs on the common duct was studied, roentgenograms being used to visualize the appearance of the biliary tract and its ability to empty itself. In an attempt to determine whether the spasm noted at the lower end of the duct was due to spasm of the sphincter

of Oddi, either with or without an associated spasm of the duodenum, McGowan and Knepper³ obtained most interesting results.

THE SPHINCTER OF ODDI

Apparently the first description of the sphincteric mechanism at the lower end of the common bile duct was by Gage⁴ in 1879, although Boyden⁵ stated that "Vesalius (1543) must be credited with calling attention to the membranes that prevent regurgitation of duodenal content (into the common bile duct), to the tortuousness of the entrance of the duct into the intestine, and to some impeding flow from the orifice (of the common bile duct)". Boyden stated further that "Oddi's historical investigations were virtually restricted to animals. He demonstrated 'a more or less pronounced bed of circular fibres encircling the choledochal canal. He was the first to measure the resistance of the sphincter, to demonstrate that removal of the gall-bladder caused a marked dilatation of the bile ducts and to postulate that dysfunction of the sphincter might explain certain morbid affections of the biliary tract—a prophecy which has recently become strikingly realized in the condition known as 'biliary dyskinesia' (Westphal 1923, Ivy, 1934)." (Best and Hicken,⁶ 1935, Hicken, Best and Hunt,⁷ 1936).

Hendrickson⁸ (1898), in an excellent study of the musculature of the entire extrahepatic biliary system in dogs, rabbits and man, presented what is now regarded as the classic description of the musculature surrounding the lower end of the common bile duct (fig 1). Nuboer⁹ in 1931, after studying the extrahepatic biliary system, was able to show in microscopic sections of the sphincteric area the relationship of the musculature of the lower end of the common bile duct to the musculature of the duodenum (fig 2). For an excellent summary of these and other anatomic studies on the subject it is suggested that one refer to Boyden's recent papers.

Further experimental work indicating the importance of the sphincter of the common bile duct in surgical conditions, was presented by Judd and Mann¹⁰.

in 1917, who demonstrated that the dilatation of the common bile ducts of dogs which follows removal of the gallbladder does not occur when the sphincter of the common bile duct is cut at the time of cholecystectomy. Changes of pressure in the common duct were measured by Potter and Mann¹¹ by inserting a T tube into the

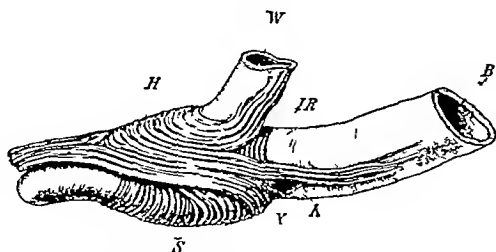

Fig 1—Macerated duodenal portion of common bile duct of man showing musculature of the duct and of the sphincter (after Hendrickson)

common bile duct of the dog. They discovered that pressure in the duct increased markedly following cholecystectomy. They found that rhythmic changes in pressure occurred and that the pressure could be influenced by the diet of the dogs, for instance, milk caused the highest pressure, dog biscuits gave an intermediate reaction, and fasting was accompanied by the lowest pressure. Giordano and Mann¹² showed that alkali placed in the duodenum increased, and acid decreased, the resistance of the sphincter of the common bile duct of the dog. They also demonstrated specimens obtained at postmortem examination of human beings who had had cholecystitis and duodenal ulcer, the musculature of the sphincter had undergone hypertrophy.

Kitakoji¹³ found that preparations which excite the parasympathetic nerves also stimulate the tonus of the sphincter of Oddi, both in vivo and in vitro. He found that muscarine, pilocarpine, physostigmine and espe-

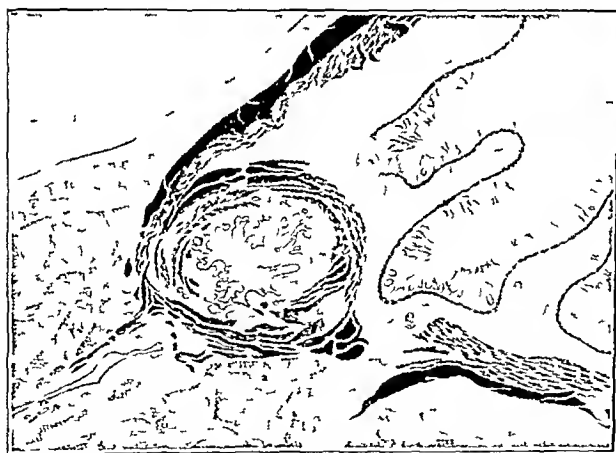

Fig 2—Transverse section showing musculature of the common bile duct at the beginning of the junction with pancreatic duct (after Nubner)

cially acetylcholine produce this action. Atropine and scopolamine paralyze the parasympathetic nerves and relax the tonus of the sphincter of Oddi. Epinephrine

and ergotamine tartrate produce slight change or no change in the intrabiliary pressure. He demonstrated that morphine and nicotine cause a contraction of Oddi's muscle.

Shi¹⁴ confirmed Kitakoji's work and, in addition, demonstrated that solution of posterior pituitary relaxes the sphincter of Oddi. Blass¹⁵ suggested that in the treatment of postcholecystectomy colic 0.06 Gm. of papaverine in 10 cc. of water should be administered through a duodenal tube in order to relax the muscle of the sphincter. A solution of magnesium sulfate should then be placed in the duodenum in order to cause a flow of bile.

The importance of the function of the sphincteric mechanism at the lower end of the common bile duct and the clinical application of knowledge concerning it in the management of disease of the biliary tract have of late been receiving a great deal of attention. before²⁰ Briefly it consists of a water manometer which is connected to the T tube at the level of the subject's abdominal wall. A bottle which is fastened high enough to act as a reservoir, is connected with the system in order to fill it with sterile physiologic solution of sodium chloride and to provide a source of supply

Fig 4—Common bile duct left before administration of morphine right after subcutaneous injection of 0.01 Gm of morphine sulfate

when it is desired to perfuse the common bile duct with a quantity of this solution. Thus two readings were obtained: (1) that for the intrabiliary pressure, which is obtained by observing the height at which fluid will stand in the manometer, and (2) that for the perfusion pressure, which is obtained by observing the height at which the fluid must be raised in the manometer in order that the resistance of the sphincter at the lower end of the common bile duct may be overcome and the fluid may flow into the duodenum. For the purpose of obtaining permanent records a U shaped manometer that contained a float and writing point which was in contact with a smoked drum was substituted for the water manometer. Roentgenograms of the common bile duct, which are made after the injection of an opaque oil (brominol), afford a further method of studying the mode of action of the drugs used.

DRUGS WHICH PRODUCE SPASMODIC CONSTRICTION AT THE LOWER END OF THE COMMON BILE DUCT

The first observation of significance was that subcutaneous injection of one-sixth grain (0.01 Gm) of morphine sulfate caused an increase in the intrabiliary pressure from the normal of from 0 to 20 mm of water to from 200 to 300 mm of water. This elevation of pressure began from two and a half to five minutes after the injection of the morphine and reached its maximum in fifteen minutes. Concomitant with this rise in pressure the patient may experience an attack of biliary colic. In other cases there may be no pain but only a sense of epigastric tightness and fullness. The injection of morphine frequently will produce an increase in intrabiliary pressure without evoking pain. The pain, which originates in the epigastrium and right upper quadrant of the abdomen and extends to the right subscapular region has been found to follow the administration of morphine only in cases in which relief is sought because of the "postcholecystectomy syndrome."

²⁰ McGowan J M, Butsch W L and Walters W L. Pressure in the Common Bile Duct of Man: Its Relation to Pain Following Cholecystectomy. *J A M A* 106:2227-2230 (June) 1936.

After the administration of morphine the value for the perfusion pressure also was elevated from a normal of from 150 to 200 mm of water to from 400 to 450 mm of water.

The effect of morphine on the common bile duct is prolonged. The pressure in the common bile duct may remain elevated two hours or more after the administration of this drug.

Injection of one-third grain (0.02 Gm) of pantopon (the hydrochlorides of the alkaloids of opium, principally morphine), one thirty-second grain (0.002 Gm) of dihydrid or 1 grain (0.065 Gm) of codeine produce an elevation of both the intrabiliary pressure and the perfusion pressure, but the elevation was neither so swiftly produced nor so high as that which follows the injection of morphine (fig 3).

The means by which these drugs cause an elevation of the intrabiliary pressure and delay in the emptying of the common bile duct is well shown by roentgenograms. The roentgenograms of the common bile duct which are shown in figure 4 were made before and after the administration of one-sixth grain (0.01 Gm) of morphine. The sharp constriction of the lower end of the common bile duct effectually prevented the emptying of the duct. This blocking of the common bile duct dammed back the medium and caused it to enter the hepatic ducts (fig 4).

DRUGS WHICH RELAX SPASMODIC CONSTRICTION AT THE LOWER END OF THE COMMON BILE DUCT

Inhalation of amyl nitrite produced an immediate and dramatic decrease of the elevated intrabiliary pressure to zero. Simultaneously with this fall there was a prompt relief of the pain or of the feeling of fullness which accompanied the elevated pressure. Inhalation of amyl nitrite will instantly lower the elevated intra-

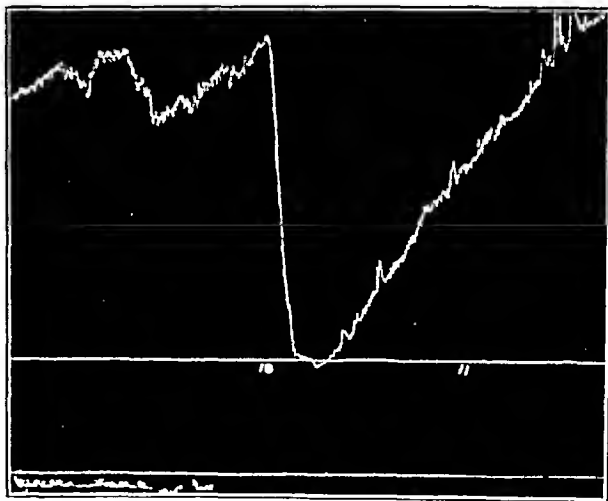

Fig 5—Effect of inhalation of amyl nitrite on increased intrabiliary pressure caused by injection of morphine sulfate.

biliary pressure, whether it is spontaneous or the result of injections of morphine. In the latter case the relaxation produced by inhalation of amyl nitrite is prompt but immediately afterward the pressure begins to increase slowly until it reaches its former level. This is the result of the prolonged action of morphine (fig 5).

Administration of glyceryl trinitrate in doses of one one-hundredth grain (0.0006 Gm) produced a decrease

in the elevated pressure, which was less marked but more lasting than that which was produced by inhalation of amyl nitrite, but if the elevation in pressure was the result of injection of morphine, it again increased to its former height. As glyceryl trinitrate produces a more lasting decrease in the pressure than does inhala-

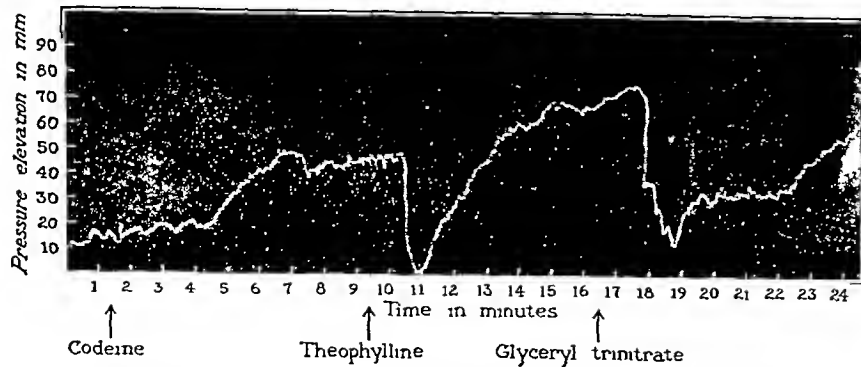

Fig. 6—Comparison of the effects of glyceryl trinitrate and theophylline with ethylenediamine on elevated intrabiliary pressure

tion of amyl nitrite, the former drug is of more value for therapeutic purposes. It is effective when placed under the tongue.

Intravenous administration of 4 grains (0.24 Gm.) of theophylline with ethylenediamine produced a relaxation of the sphincteric mechanism similar to that produced by inhalations of amyl nitrite. Figure 6 shows a comparison of the actions of theophylline with ethylenediamine and glyceryl trinitrate on the elevated intrabiliary pressure of a patient who previously had received 1 grain (0.065 Gm.) of codeine hypodermically.

The roentgenograms of the common bile duct show very graphically how inhalation of amyl nitrite relaxed the spasm at the lower end of the common bile duct which morphine produced, and how the former drug caused emptying of the hepatic and common bile ducts (fig. 7).

THE ACTION OF OTHER ANTISPASMODIC DRUGS

Other drugs which generally are believed to have an antispasmodic action were tested for the effect on the sphincteric spasm caused by injection of morphine.

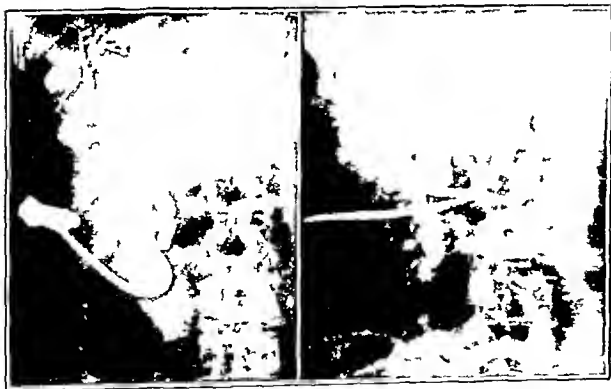

Fig. 7—Left spasm of lower end of common bile duct following injection of 0.01 Gm of morphine sulfate; right relief of spasm by inhalation of amyl nitrite.

The drug to be tested was first injected so that we might be sure that it did not elevate the intrabiliary pressure. Then one-sixth grain (0.01 Gm.) of morphine was injected and a few minutes later, after the elevation of pressure produced by the morphine had reached its maximal height, another dose of the drug to be tested

was given. In this manner it was found that injection of one seventy-fifth grain (0.0009 Gm.) of atropine produced dilatation of the pupils and dryness of the mouth but did not relax the sphincteric spasm caused by the injection of the morphine. An injection of one one-hundredth grain (0.0006 Gm.) of scopolamine hydrobromide did not have any effect on the spasm of the sphincter (fig. 8).

Other drugs which have been prescribed because of their ability to relax spasm of other muscular organs were administered in order to determine whether they would lower the intrabiliary pressure produced by injections of morphine. Forty milligrams of muscle relaxant, 30 cc of alcohol, 0.6 mg of histamine, three fourths grain (0.05 Gm.) of epinephrine and 1 cc of a 1:1,000 solution of epinephrine did not have any effect on the pressure in the common bile duct when they were administered subcutaneously at different times. Intravenous administration of 10 cc of a 10 per cent solution of calcium chloride

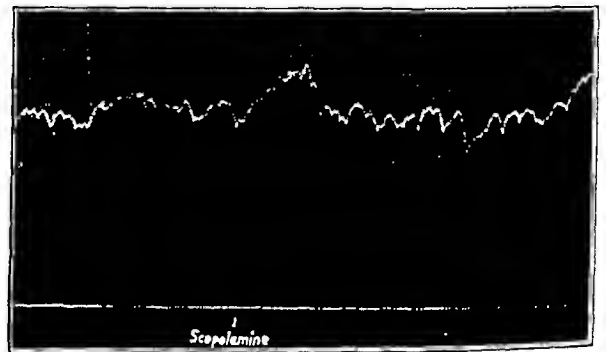

Fig. 8—Effect of injection of 0.0006 Gm of scopolamine hydrobromide on increased intrabiliary pressure caused by injection of morphine.

also failed to lower the pressure. No decrease in the pressure was noted after the intravenous administration of one-half grain (0.032 Gm.) of papaverine hydrochloride or after the intramuscular administration of 3 grains of the same drug.

Of the parasympathicomimetic drugs, both physostigmine and acetylcholine were tested, but no effect on the intrabiliary pressure was noted. The synergistic action of these two drugs was recognized and they were administered in combination, that is, 100 mg of acetylcholine was given twenty minutes after the administration of one twenty-fifth grain (0.0026 Gm.) of physostigmine, but no further effect was noted.

Administration of 0.5 cc of a 1:2,000 solution of ergotamine tartrate, 7½ grains (0.5 Gm.) of caffeine and 2 grains (0.12 Gm.) of phenobarbital sodium at different times, likewise produced no effect. All the drugs were administered hypodermically unless otherwise stated.

DUODENAL MOTILITY

During the course of these studies we were aware of the fact that it would be necessary to try to determine whether the increase in pressure within the common duct could be attributed to spasm of the sphincter of the common duct (Oddi) alone or to spasm of the sphincter of the common duct in combination with

spasm of the duodenum (acting on the intraduodenal portion of the common duct), the result of increased duodenal peristalsis. This opinion was expressed in an editorial²¹ published in August 1936.

It will be recalled that Orr²² in 1933 presented experimental evidence of the stimulating effect of small doses of morphine on intestinal peristalsis. To study the problem properly in human subjects it is necessary that the motility of the duodenum be recorded by means of a rubber balloon lying in the duodenum. This is difficult to place properly and, although Knepper is continuing to work on methods of recording such movements through a closed, intrinsic pressure apparatus, the studies presented have been made with an open tube in the duodenum. Barium sulfate is injected into the duodenum through this tube and brominol is simultaneously injected into the common duct through the T tube. The pressure recording apparatus is then connected to the T tube. Roentgenograms are made to determine normal appearance of these simultaneously injected structures (fig 9). An injection of morphine is then given hypodermically, the changes in intraductal pressure are recorded and roentgenograms are taken. Following the injection of morphine contraction of the duodenum can be

noted to occur simultaneously with spasm of the lower end of the common duct, with a descent of 2 cm in the position of the area of spasm of the common duct. The biliary tract, both extrahepatic and intrahepatic, fills with the opaque substance and pain is experienced by the patient (fig 10). On inhalation of amyl nitrite, pain is relieved, spasm of the duodenum is

Fig 9—Outline of duodenum (barium sulfate) and common duct (brominol)

released, the lower end of the common duct relaxes, and the opaque fluid in the common and hepatic ducts is discharged into the duodenum (fig 11). Further studies are being undertaken to see whether independent stimulation of these structures, namely, the sphincter of Oddi and the duodenal wall, cannot be accomplished in order to determine whether they act independently or whether one influences the other.

SUMMARY AND CONCLUSIONS

The data which we have collected suggest that the administration of morphine is likely to precipitate an attack of biliary colic in some patients with lesions of the biliary tract. Administration of one-sixth grain (0.01 Gm) of morphine in such cases will frequently produce an increase of intrabiliary pressure to from 160 to 300 mm of water for two or more hours, accompanied by severe pain. While a large dose of morphine will decrease sensibility to pain by acting on the higher nerve centers, it at the same time prolongs and even augments the increase in pressure in the common bile duct.

Morphine, codeine and dilaudid produce a marked increase in the pressure within the common bile duct because they produce a spasm in the sphincter at the lower end of the duct. Amyl nitrite, glyceryl trinitrate and theophylline with ethylenediamine will completely relax the sphincteric spasm and thus produce a fall in the pressure. Certain other drugs which have been tested do not have any effect on the pressure within the common bile duct.

We have studied a series of nine cases in which repeated attacks of biliary colic developed after the gallbladder had been removed. In these cases the subcutaneous injection of one-sixth grain (0.01 Gm) of morphine sulfate produced pain, which was completely relieved by the administration, under the tongue, of one one-hundredth grain (0.0006 Gm) of glyceryl trinitrate or by inhalation of amyl nitrite. In two of these cases, stones were subsequently found in the common bile duct at operation.

In two of the cases pain, which was associated with biliary colic and which occurred before cholecystectomy, was relieved by the administration of glyceryl trinitrate. In three other cases the patients were relieved of similar attacks which occurred shortly after cholecystectomy.

Patients who have disease of the gallbladder frequently say that morphine gives them a feeling of fullness or makes them sick. The explanation probably is that a normally functioning gallbladder can maintain

intrabiliary pressure at a normal level by absorption of fluids and relaxation of its smooth muscle whereas a diseased gallbladder on the other hand, does not possess this function. We suggest the use of morphine as a diagnostic procedure in the study of patients who have the postcholecystectomy syndrome.

If the administration of morphine brings on an attack of pain and glyceryl trinitrate relieves it, the evidence is in favor of the condition being the result of a disturbance in the sphincteric mechanism at the lower end of the common bile duct, either with or without associated stones in the duct. Administration of glyceryl trinitrate in doses of one one-hundredth grain (0.0006 Gm) will

relieve the pain associated with the postcholecystectomy syndrome. We do not recommend its use except as a temporary measure, until after the common bile duct has been explored, since stones in the common duct frequently account for the sphincteric spasm.

We have not noted any untoward effects from the use of glyceryl trinitrate except a feeling of warmth, weakness, and occasionally of tightness in the head. These are purely transitory, however, and pass off in a few minutes. However, we recommend that the patient be in the recumbent position when the drug is taken. We have found that the tablets made for hypodermic use are more effective than the regular triturates.

ABSTRACT OF DISCUSSION

DR A. C. ILL, Chicago. Dr Walters and his co authors are extending to the human being in the clinic under well controlled conditions observations which have been made on animals and medical students. I believe that a spasm of the sphincter of Oddi does occur in the human being and is not infrequently responsible for the production of symptoms and disorders of the biliary tract. Morphine, which the authors have used to produce the spasm or hypertonus of the sphincter, is the drug which Dr Lueith in my laboratory used to show the relation between duodenal tone and motility and the resistance offered to the flow of bile from the common duct into the duodenum. So I can accept the observation without any reservation that morphine will increase the resistance to the flow of fluid from the common duct into the duodenum. I am not surprised that the antispasmodics used decrease this resistance. I am surprised however that the authors did not get some decrease in resistance with atropine. Of course, they used only one seventy-fifth of a grain (0.0008 Gm.) and we generally employ from one fortieth to one sixtieth of a grain (0.0016 to 0.0010 Gm.), a larger dose. I have observed that atropine relaxes the sphincter in the animal and possess indirect evidence that one sixtieth of a grain of atropine hypodermically will do the same in man. It is surprising that pain is experienced by a patient from an increase in pressure of only from 10 to 20 cm. of water pressure. Normally the biliary passage is subjected to a pressure of 10, 15 or 20 cm. of bile and no pain is experienced. I should like to ask the authors in that regard how quickly they raised the pressure. As a general rule the speed with which the pressure is increased is important in the production of visceral pain of any sort. I have an idea that, if the pressure was exerted more slowly, pain might not result.

DR ROBERT L. PAYNE, Norfolk, Va. The authors have pointed out types of cases of disturbance in the common duct in which they have placed a T tube for drainage. Practically seven methods of trying to determine the condition of the sphincter of Oddi are recognized: (1) injection of saline solution through the tube; (2) clamping of the T tube to shunt the bile down; (3) the food test; (4) the question of bile in the stools; (5) Reid's hydrostatic test which is very valuable; (6) the question of bilirubinemia; and (7) X-ray visualization. Of all these except X-ray visualization the most valuable is clamping of the tube. Even though it does not produce pain and apparently is turning all the bile through the sphincter into the duodenum, this does not mean that such an act is taking place, because study of the blood shows that frequently after the tube has been clamped for twenty-four hours the serum bilirubin will be found to have risen above the previous normal level. X-ray visualization should be used in preference to all other methods. The authors have called attention especially to the value of the X-rays in showing obstruction at the sphincter of Oddi, whether due to stone or spasm, postoperatively. I would emphasize the value of X-ray delineation of the common duct and particularly obstruction at the sphincter of Oddi at the time of operation. My associates and I have done about seventy-five of these sorts of which have been visualizations at the time of the operation. Some of these cases of postcholecystectomy colic we have eliminated by the deter-

mination by means of X-rays at the operation that there was a small stone or two small stones located at the sphincter that could not be felt, or that there was spasm and obstruction at the sphincter from some form of disturbance. Surgeons rather broadly postulate that in cholecystitis there is some hypertrophy of the sphincter. Bakes, Allen and others have attempted to overcome this by dilation when it could be demonstrated in the operative table by exploration of the duct or not with X-ray visualization. I have tried this dilation a good many times. I don't know whether the sphincter stays dilated. I doubt the propriety of the method as a routine to the point where one carries it up to 10 mm. as Bakes advocates. The authors have brought the relief of pain in undetermined types of postcholecystectomy colic by the use of amyl nitrite or glyceryl trinitrate. I cite the case of a woman who had stones in the common duct after cholecystectomy but who could not come for operation for various reasons. I gave her hypodermic tablets of glyceryl trinitrate and she was able to get relief from putting one or two of these under her tongue during the repeated attacks of colic.

DR R. RUSSELL BEST, Omaha. Inspired by Dr Ill's publications some three years ago, I began injecting radiopaque substances into the common duct at the table, and through T tubes or fistulas following operation. I discovered that the sphincter of Oddi was usually contracted under anesthesia, and not infrequently following operation, and that morphine, atropine or a combination of these had an inconstant effect on this spastic state. Glyceryl trinitrate, although not always effective, was found to be more consistent than atropine in relaxing the sphincter. During the last year I have experimented with increasing the flow and pressure of bile within the common duct and have displaced stones from the common duct into the duodenum. I operated on a patient in whom palpation, probing and irrigation revealed nothing within the common duct. A cholangiogram one week later showed a filling defect at the lower end of the common duct and one ten days later identified this as a stone. I gave dehydrocholic acid to increase the flow and pressure of bile. Taking the readings was a little difficult because I was working against a sphincter the status of which I do not know or understand. In conjunction with the acid I gave the antispasmodics atropine and glyceryl trinitrate and magnesium sulfate to relax the sphincter from the duodenal side and also injected warm olive oil into the common duct to relax the sphincter from the choledochal side. By repeating the treatments over a period of a month, I dislodged the stone, as proved by a cholangiogram. I operated on a woman and opened her common duct, but no stones were discernible. One week later a cholangiogram revealed that the common duct was filled with stones. The foregoing treatment was instituted and a cholangiogram repeated in four days. Only one stone remained at the lower end of the common duct. Nine had been recovered from the stools. The treatment was repeated and the last stone was passed. The cholangiogram reveals no stones in the duct. I cannot advocate the routine use of dehydrocholic acid to wash these stones out of the liver and common duct unless one has a safety valve in a T tube or fistula. I might add that I have used it in cases in which these were not present, but with full appreciation of its dangers.

DR WALTER WALTERS, Rochester, Minn. Of the problems presented today let us take the method of visualizing the common bile duct postoperatively by injecting an opaque substance into it. This has enabled one to visualize among other things a persisting common duct stone overlooked at the time of operation. I want to mention a case, because after fragmenting the stone with ether, as suggested by Pribram, and diluting the ether with alcohol so as to increase the intraductal pressure relaxation of the sphincter of Oddi was accomplished by amyl nitrite and the stone fragments were forced through the duct into the duodenum. Dr Payne's suggestion regarding the use of hippuran is an excellent one and we will try it. Dr Pett is to be congratulated for calling attention (I think it is two years or so ago) to the value of roentgenologic examination of the duct at the time of operation. I must confess that my trials with it at operation have not been as satisfactory as I would have liked so I have more or less relied on clinical manifestations of common duct obstruction: palpation, etc.

is not accurate), exploration of the interior of the duct, which is very accurate if one can explore the intrahepatic as well as common ducts, and dilation of the end of the common bile duct with scoops. Relative to the underlying cause of the spasms of the sphincter of Oddi which persist after cholecystectomy when there is neither pancreatitis nor common duct stone but when there is increased resistance or spasm of the sphincter of Oddi, what is best to do with such patients? These cases continue to be ones in which further study may determine effective methods of overcoming such spasms.

THE LATE EFFECTS OF ACUTE PYELITIS IN GIRLS

LAWRENCE R WHARTON, M D

LAMAN A GRAY M D

AND

HARRIET G GUILD, M D

BALTIMORE

What is the ultimate effect of pyelitis in girls? Does it clear up completely, leaving a perfectly normal urinary tract? Or may it leave behind residues which although symptomless, may predispose toward subsequent recurrence? Is the child who has had only one attack of pyelitis less liable to suffer persisting damage than the child who has had repeated attacks? Is it possible that the effect of pyelitis in childhood may persist asymptotically into adult life, thus correlating the two great groups of urinary infections?

The object of our study has been to try to answer some of these questions, because these particular problems are important and have not received the attention they deserve. This is a preliminary report, as we expect to continue our studies. It is quite probable that the answer to these questions will definitely affect our attitude toward the treatment of urinary infections in girls.

We use the term pyelitis rather loosely when referring to childhood. Strictly speaking, one should employ the term urinary infection unless infection is actually demonstrated in the upper part of the urinary tract. Practically however, the word pyelitis is so well established and the clinical picture so definite that we continue to use it, with the aforementioned reservation.

METHOD OF INVESTIGATION

From the files of the Harriet Lane Home for Invalid Children (the Pediatric Department of the Johns Hopkins Hospital) we obtained and studied the histories of girls who had had urinary infections years ago. In addition, Dr Gustav Woltebeck furnished the records of four private patients whom he had treated for pyelitis in infancy. This gave us a group in which we could observe the late effects of uncomplicated urinary infection in fairly normal and healthy children. Through the social service department we tried to find and induce these former patients to return for study. It is at once evident to persons who have made any such follow-up studies that we were attempting a rather difficult task in inducing high school pupils, young mothers or employed women to return for urologic

study, because most of them were perfectly well and knew nothing of their childhood illness or had dismissed it from their minds.

Our method of investigation had to be suited to this situation. Obviously, we could not perform any investigations which might be painful or cause reactions or incapacitation. In other words, we could not ask too much of the subjects because they had already granted us the favor of returning for the examination. We assumed the entire responsibility for the procedure.

The investigative procedure was therefore a compromise between our desire to make a complete genito-urinary and cystoscopic examination and the necessity of interfering as little as possible with the daily occupation of these young women. The procedure we adopted was as follows: (1) history, (2) physical examination, (3) examination of catheterized specimen of urine from the bladder, (4) culture of urine from the bladder, (5) intravenous phenolsulfonphthalein test for thirty minutes, (6) intravenous urography.

This method of examination is practically painless, causes no incapacitation and enables the patient to

Fig 1 (case 2).—At the age of 4 years this patient had one attack of acute urinary infection. She had no further urinary disorders. Follow up study at the age of 20 showed occasional leukocytes in the urine and colon bacillus infection. The upper part of the ureters are dilated and redundant; the right ureter is redundant and the left ureter is angulated. The patient is in excellent general health; the only symptom being occasional pain in the back.

return to her duties immediately afterward without any further inconvenience. It requires about one hour. We realize that such an examination falls short of our ideal in many ways. As far as we know, however, ours is the only comprehensive attempt to study this particular problem.

RESULTS OF THE FOLLOW-UP STUDY

Thirty of the former patients have returned for follow-up study. For convenience we have divided them into two main groups: (1) those who had only one attack of pyelitis in childhood and (2) those who had more than one attack. The patients in each of these groups are then classified into two subgroups according to their condition at the present time. (A)

From the Departments of Gynecology and Pediatrics of the Johns Hopkins Hospital and the Johns Hopkins University School of Medicine. Read before the Section on Urology at the Eighty-Eighth Annual Session of the American Medical Association, Atlantic City, N. J., June 9, 1917.

Dr John W. Pierson and Dr Charles A. Waters of the roentgenologic department of the hospital examined all urograms. The Winthrop Chemical Company supplied the diodrast and the Mallinckrodt Chemical Works the hypuran used in this study.

those who at present have a normal urinary tract and (B) those who now have urinary abnormalities. The thirty former patients are thus classified as follows:

1 Those who had only one attack of pyelitis in childhood, nine patients. A Normal urinary tract now, three patients. B Urinary abnormalities now, six patients.

2 Those who had more than one attack in childhood, twenty-one patients. A Normal urinary tract now, nine patients. B Abnormal urinary tract now, eleven patients.

We shall consider these groups in the order named, presenting tables which show the clinical data relating to the urinary infection of childhood and other tables which present in detail the results of the urologic examinations of the same patients made years later, in our present follow-up study.

THE EFFECT OF ONE ATTACK OF PYELITIS IN CHILDHOOD

In table 1 we have summarized the clinical data recorded during the former urinary infection in the histories of these nine children who had only one attack diagnosed clinically as acute pyelitis, at ages ranging from 10 months to 4 years. During their illness, they presented only the usual characteristics found in patients with fairly severe acute pyelitis.

Table 2 shows the present condition of the urinary tract of the same nine persons. Their present ages vary from 10 to 20 years. On the average, thirteen years has passed since their former urinary infection. All but one are now in excellent or good health, the health of one is fair. Not one of these young women is aware of any urologic disorder or has sought professional advice because of any urinary symptoms.

Fig 2 (case 4)—At the age of 2 years this patient had one attack of pyelitis; she had no further urinary disorders. Her present age is 10 years. The urine now contains streptococci as it did eight years ago. The urogram shows a small stone in the highest calyx of the left kidney.

Urologic examination of three of the nine revealed no disorder whatever; they are now completely normal.

Six of the subjects, however, showed definite though usually slight abnormalities on urologic study. They had no spontaneous complaints, but, on questioning, we found that one had nocturia, one had enuresis and

one occasionally had pain in the back (fig 1). Our examination showed that three have a varying number of leukocytes in the catheterized urine from the bladder, five have positive urinary cultures, one has a distinct diminution in renal function and five have urographic abnormalities. One has a small stone in the left kidney.

Fig 3 (case 13)—Beginning at the age of 4 years this patient had recurrent urinary infections for five years. Her present age is 13 and her general health excellent. The urine is normal and sterile. The urogram shows a dilated right ureter. The patient has pain in the right flank at times.

(fig 2), four show slight grades of ureteral or pelvic dilatation. One girl who had streptococci in the urine eight years ago shows the same organism now.

In summary, then we have made urologic examinations of nine girls or young women who had only one attack of pyelitis, on the average thirteen years ago. Three of these have perfectly normal urinary tracts now, in six we found slight though definite pathologic changes in the urinary tract. All but one of these persons look perfectly well and are in good health.

THE EFFECT OF REPEATED ATTACKS OF PYELITIS IN CHILDHOOD

Table 3 outlines the clinical data observed during the repeated attacks of urinary infection in a group of ten children who now have completely normal urinary organs. In this group the age at onset varied from 1 to 5 years. The attacks recurred for a number of years varying from one to five. On the average ten years has passed since the last attack, the longest period of observation being nineteen years. None of these children suffered any permanent urinary damage whatever, although they had repeated attacks of pyelitis.

Table 4 outlines the clinical data on a group of eleven children who had repeated attacks of pyelitis years ago and who still have persisting pathologic changes in the urinary tract.

In general, these children had recurring attacks for a long time, varying from one to thirteen years. The average number of years during which they had recurrences was six. On the contrary, it will be noted that in the group that showed no subsequent pathologic change the recurrences in childhood continued on the

average for only two and four-tenths years. In other words, the longer the attacks continue, the greater the likelihood of permanent damage to the urinary tract.

The chronicity of the infection in childhood is the feature that distinguishes this group, the individual attacks seemed to show no unusually severe characteristics.

Table 5 shows the present condition of the patients whose former condition is outlined in table 4. Their present ages vary from 9 to 27 years. We examined them from eight to nineteen years after their first attack and from three to fourteen years after their last attack.

The general health of the group as a whole is strikingly good. Only one person is in bad health, and two are in fair health, the general condition of the others is excellent or good.

The present symptoms of these young women usually vary with their urologic condition. One has distinct renal insufficiency, with pain in the right side and edema of the extremities. Her phenolsulfonphthalein excre-

tion is advised by urologists that she should never have any cystoscopic treatment.

This case illustrates the extreme consequence of neglected pyelitis in childhood—chronic, recurring infection which persists throughout life, a nephrectomy which may have been unnecessary, pyelitis in preg-

nancies which should never have occurred, and subsequent advice which has kept her an invalid. The greatest damage was done when she was neglected as a child.

The only other serious urologic abnormality in this group is found in case 17, a functionless shrunken kidney. This girl had recurring urinary infections between the ages of 5 and 11 years, she is now 15 years old. Urine from the bladder showed moderate pyuria with colon bacilli on our first follow-up study. Retrograde cystoscopy revealed a functionless though sterile left kidney, after the drainage from the right kidney was improved, its function increased to 60 per cent phenolsulfonphthalein excretion in thirty minutes. Although this girl has shown much improvement, it may be impossible to restore the function of her left kidney.

The remaining nine in this group are all in average good or excellent general health. One young woman, now 18 years old, has an interesting syndrome, recurring pain in the right side with fever (from 100 to 102 F) during menstruation. The removal of her appendix in 1923 had no effect on this situation. She has a urinary infection with the same organisms (colon bacilli and staphylococci) which were present seven years ago during her last definite attack of pyelitis. Her urograms are normal.

tion for thirty minutes is only 20 per cent. She is now 27 years old. Ten years ago her left kidney was removed at a local hospital presumably for infection. Her remaining kidney is hydronephrotic, ptosed and infected (fig 4). The urine contains numerous white blood cells, a few red blood cells and the Shiga dispar bacillus. She has had two pregnancies both of which were stormy, one being complicated by exacerbation of the urinary infection. This young woman has been

As table 5 shows, in all these cases there are definite urologic abnormalities. All but one subject have positive urinary cultures, all but three have varying numbers of leukocytes in the urine, five have phenolsulfonphthalein excretions below 40 per cent for half an hour and seven have urographic abnormalities. One has a small stone in the ureter.

Only two of these subjects have any notable symptoms. From seven we could elicit a history of occasional discomfort which may have been due to the urinary tract. Two have no discomforts at all. All these patients need urologic attention now.

In summary, we are presenting urologic studies of twenty-one girls and young women who had repeated attacks of urinary infection in childhood. The likelihood of permanent damage increases directly with the persistence of the infection in childhood. Approximately half of these young women still have urinary abnormalities from three to fourteen years after their childhood infection.

PYELITIS IN PREGNANCY

Only three of the thirty patients have been followed through pregnancies. One of the three had a recurrence of pyelitis at that time. Our inability to foretell what will happen in any individual case is illustrated by one particular experience. A woman now 19 years old (case 14) had pyelitis from the age of 5 years till she was 11. When examined one year ago, the catheterized urine showed albumin, colon bacilli and an occasional white blood cell. The urogram was perfectly normal. She went through her recent pregnancy without the slightest suggestion of a urinary infection,

Fig. 4 (case 18).—Urogram showing the hydronephrosis and ptotic right kidney.

although her child was born one month prematurely. Both mother and child are now apparently well. Although we rather feared that she might have pyelitis again while pregnant, she failed to do so.

FOCI OF INFECTION

While studying the histories of these thirty patients we were impressed by the frequency of tonsillitis, otitis

media and sinusitis in childhood. An analysis of this feature gave us the data which we are presenting in tables 6, 7 and 8.

In the group of nine children who had only one attack of pyelitis, tonsillitis was diagnosed only three times and otitis media once (table 6). On the con-

Fig. 5 (case 19).—At the age of 4 years this patient had one attack of pyelitis due to the colon bacillus. Her present age is 21 and her general health is good. She is married and has one child born in 1934. The pregnancy was complicated by toxemia. The patient now has beta streptococci in the urine. The urogram shows slight hydronephrosis with redundancy of the upper part of the right ureter.

trary, in the group of twenty-one children who had many attacks of pyelitis, eighteen had tonsillitis and nine had otitis media. Thirteen had a tonsillectomy. Adenitis, pharyngitis, sinusitis, bronchitis and pneumonia occurred in some cases. Three of the patients had an appendectomy, but in no case was the appendix acutely inflamed.

It therefore seems that, in the children with many attacks of pyelitis, accessory infections were much more common than in those who had only one attack. Whether any of these accessory infections might be considered focal in the usual sense cannot be concluded from this study. Thus, we found that residual urinary infections were just as common in the subjects who had had their tonsils removed as in those who had not. In spite of this fact, however, one cannot dispute the equally evident fact that the removal of diseased tonsils is good therapy, even though one cannot promise that it will have any effect on the urinary infection.

CONGENITAL ABNORMALITIES

We found no definite significant congenital abnormality in this group. In two cases there was a marked elongation of the highest calyx bilaterally, a rather spider leg appearance, which one of our radiologists suggested, might be the beginning of polycystic kidney. In another case a kidney was rotated.

SUMMARY

Only two of thirty girls and young women who had pyelitis in infancy and childhood and who were examined on the average, nine and six-tenths years after

their last attack of pyelitis, are now in poor health. Only one has been treated for any urologic disease since her childhood pyelitis. This young woman has been an invalid, owing to chronic urinary infection. She has lost one kidney, and the remaining kidney is hydro-nephrotic and infected.

Twenty-eight have had average good health since childhood, most are in excellent health.

The vast majority had no complaints whatever, symptoms when present, could be elicited only by questioning.

Our follow-up urologic examination showed that seventeen (57 per cent) have definite abnormalities in the urinary tract at the present time.

Of nine who had only one attack of urinary infection in childhood six now show urinary abnormalities.

22	0	0	Alpha strepto coci	3+	Fair	None	Right kidney rotated stone in ureter

Of twenty-one who had recurring infections in childhood, eleven now have urinary abnormalities.

In general, ten now have mechanical abnormalities, as shown by intravenous urography. Ten have varying numbers of leukocytes in the catheterized urine. In fifteen cases, cultures of the urine are positive. Two subjects have small stones.

In one case we found a functionless kidney in a girl of 15, with practically no symptoms.

Three of these young women have borne children, one has had pyelitis while pregnant.

COMMENT

The results of our examinations surprised us as much as they will probably surprise some of our readers. In this series the after-effects of pyelitis appear much more grave than we had expected them to be. And yet after all only one of the patients was really incapacitated from usual activity; all but two were in average good or excellent health. In other words, the persisting lesions were slight but definite. If it is

reasonable to suppose that the changes which we found on follow-up examination are the persisting aftermath of a childhood infection, then we must adopt a different attitude toward urinary infections in early life. We realize that this study is open to at least two definite criticisms: first, that the series is small and, second, that it may include only the most serious types of

pyelitis in childhood because practically all the children were hospitalized. Both criticisms are probably valid. It remains to be seen, however, what future studies will reveal.

With due regard for these limitations, our study has shown that urinary infections in girls cannot be dismissed casually, as has been our usual custom. They behave just as they do in adults and require just as careful attention. This does not mean that all children with pyelitis should be examined cystoscopically, because half of them even though they have severe

grades of infection, recover completely and have normal urinary tracts afterward. But our study shows that one can never tell just what patients will show complete recovery.

Consequently, we advise that after symptomatic recovery is complete and after the child has been well for several months (long enough for her to throw off the infection completely if she can do so), one should make a follow-up study such as we have made in this series. If a residual lesion is present, it should receive appropriate treatment.

1201 North Calvert Street

NONOBSTRUCTIVE DILATATIONS OF UPPER URINARY TRACT IN CHILDREN

ALEXANDER B. HEPLER, M.D.

SEATTLE

From the etiologic standpoint, dilatations of the upper part of the urinary tract in children may be divided into three groups: (1) those due to mechanical obstruction, most frequently congenital fibrosis, muscular hypertrophy or exaggerated constriction at the points of normal anatomic narrowing, the ureteropelvic and ureterovesical junctions and the vesical outlet; (2) those that are a sequence of neurologic lesions either central or peripheral involving the bladder, such as poliomyelitis, cerebrospinal syphilis, spina bifida, toxic neuritis or the less definite dysfunctions classified as idiopathic; (3) those in which no obvious cause either mechanical or dynamic can be demonstrated.

The confusion which exists concerning the pathogenesis of the dilatations in the last group is attested by the variety of terms used to describe them. Speculation as to etiology is usually divided between embryologic developmental, intrinsic inflammatory or neurogenic causes. It has included the contention that the dilatation is the result of a persistence of the sausage type of fetal ureter, hypoplasia of the muscularis, fetal ureteral valves which have disappeared, a congenital primary motor functional defect or atony, disturbance either central or peripheral of the nerves supplying the ureter, hypoesthesia and hyperesthesia of the mucosa, inflammatory atony, insufficiency of the ureterovesical valves with vesico-ureteral reflex, vesical spasm, and, more recently, intrinsic ureteral functional imbalance. Some urologists do not admit the existence of so-called idiopathic dilatation but contend that, if carefully looked for, obstruction of some sort will be found or at least has existed at some time.

From personal experience and a review of the increasing literature on this subject, the impression is obtained that in many cases dilatation called primary because no obstruction can be found, and therefore assumed to be a developmental or functional defect of the ureteral wall itself, is really secondary.

Although no organic obstruction is present, the dilatation in some instances follows functional imbalance at the ureterovesical junction. Neuromuscular disturbances at this point offer resistance to ureteral emptying and set in motion the same physical and dynamic factors which produce the dilatation in the mechanical obstructions. The urinary tract's reaction

to the stasis of functional retention is no different from that of mechanical obstruction. In advanced neurogenic lesions the process may be hastened by neurotropic changes in the musculature, but in the segmental imbalances such as abnormal activity of the sphincter, the condition may be considered as a true obstruction. The progressive changes are the same.

Confusion has arisen from the tendency of some authors to consider various phases of the same disorder as pathologic entities having separate etiologies. Two types of nonobstructive dilatation which have been described are the congenital megalo-ureter with a thickened, hypertrophied muscularis and the enormously dilated thin-walled, atrophic, atonic ureter.

In the former quite frequently there is little ureteral elongation or tortuosity and at times comparatively little pyelectasis. The muscularis is hypertrophied, and it has been shown that although the dilatation is marked the ureter may be hypertonic. The condition has been compared to Hirschsprung's disease and has been attributed to an embryologic developmental defect of the ureteral wall.

In the latter the ureter consists of a dilated atonic tube of connective and fibrous tissue with inflammatory round cell infiltration and very little muscularis. The condition has been attributed to primary atony, to a developmental defect of undergrowth or hypoplasia and to intrinsic inflammatory changes without ureteral obstruction.

Although these conditions may be distinct entities, it has not been sufficiently emphasized that one may be the end stage of the other and that the two may be the result of a reaction to the same etiologic factor, resistance to ureteral emptying from a functional imbalance at the ureterovesical junction. The first represents a stage of compensation with muscular hypertrophy and hypertonicity comparable to the compensating hypertrophy of the bladder due to obstruction of the vesical neck. The second represents the end stage of broken compensation brought about by continuous or progressive stasis or the onset of infection, with inflammatory changes and the introduction of secondary obstructive factors, a clinical picture similar to that seen with any of the obstructive uropathies.

The compensating stage may be short or absent, and secondary changes appear early. On the other hand, because resistance to ureteral emptying is apt to be less unyielding in the functional imbalances of the lower part of the ureter than in the mechanical obstructions, compensating hypertrophy with dilatation confined to the ureter and the absence of elongation and tortuosity are more apt to be found with the neuromuscular dysfunctions and, therefore, have been considered characteristic of nonobstructive dilatation.

The clinical picture and the cystoscopic appearances as observed in four children with varying degrees of hydronephrosis and hydro-ureter are presented to add to the steadily growing evidence that in at least some cases dilatation may be the result of a disturbance of ureteral dynamics or of functional imbalance at the ureterovesical junction.

URETERAL DYNAMICS

The innervation of the ureter is entirely autonomic and in the upper third comes from the renal plexus, in the middle third from the spermatic plexus and in the lower third from the hypogastric ganglion. Ganglion cells are present in the adventitia only and are most abundant in the lower and intravesical portion. Some

are found in the region of the ureteropelvic junction. Activity is greatest in the portion where the ganglions are most numerous. Stripping a segment of adventitia from the whole circumference results in atony and dilatation above that point.

The mechanism responsible for ureteral activity is not thoroughly understood. It can be said that peristalsis is automatic and can be initiated from

Fig 1—Cystogram showing vesico ureteral reflux in a boy of 5 years who died of urosepsis. Despite the autopsy report of no obstruction of the urinary tract, the evidence of chronic distention of the bladder (1) dilatation (2) irregular outlines with cellulæ and (3) vesico ureteral reflux (regurgitant orifices) indicated obstruction in the lower part of the tract or neuromuscular vesical dysfunction.

intrinsic influences in the isolated ureter, that it is partly neurogenic and not the property of smooth muscle alone. Despite its automaticity it is under some control of the autonomic nervous system and can be modified through the sympathetics.

The lower and intramural part of the ureter and the vesical trigon may be considered as an anatomic and physiologic unit. They have a common embryologic origin, which is distinct from that of the rest of the bladder.¹ The muscles of the trigon are formed from a continuation of the longitudinal fibers of the ureters, the lateral extensions forming Bell's muscle and the mesial extensions which unite with those of the opposite side forming Mercier's bar. Fibers from the central muscle of the trigon loop about the intramural portion of the ureter.

Pharmacologically it has been shown that this unit has a common nerve supply and responds to drugs differently than the rest of the bladder. It receives fibers from the hypogastric nerves only, and stimulation of these nerves produces a strong contraction of the intravesical ureter where the ganglions are most numerous and of the adjacent trigon.²

This neuromuscular arrangement has considerable functional significance. Although there is no circular muscle comparable to the anal sphincter, the ureterovesical valve cannot be considered a simple mechanical device due to the obliquity of the intravesical ureter. There is evidence on cystoscopic meatoscopy that it takes a part in ureteral dynamics. There is active relaxation with opening of the orifice synchronous with the termination of the peristaltic wave. This is followed by a period of contraction, or expulsive effort, at which time the orifice is of pinpoint size and is drawn upward and outward with the adjacent trigon or ureteral mound. There may then be partial relaxation followed by a second contraction or expulsive effort, after which there is complete relaxation with a return of the slitlike orifice to its normal position and shape. The process is comparable to the action of the levator ani muscles in completing the act of defecation.

DISFUNCTIONS

It is not illogical to assume that there may be disturbances in ureteral activity which are comparable to those recognized in like mechanisms for the emptying of an involuntary or smooth muscle tube with a sphincter at its distal end, such as the gastro-intestinal tract.

In this discussion I am not concerned with the neuromuscular disequilibrium of renal sympathetic origin, the so-called renal sympathicotonia or hyperdynamic activity, but only with segmental imbalance at the ureterovesical junction, of which two types have been described: (1) increased tonicity or spastic contraction and (2) achalasia. A number of cases of the first type have been reported, and Braasch⁴ has noted two in which the abnormal tonicity was overcome and ureteral drainage improved by a presacral neurectomy.

The foreign literature contains an increasing number of reports of cases of the second type, or achalasia.⁵ Here there is incoordination between ureteral peristalsis and the relaxation and expulsive activity at the ureterovesical junction. The "law of the intestine," that is,

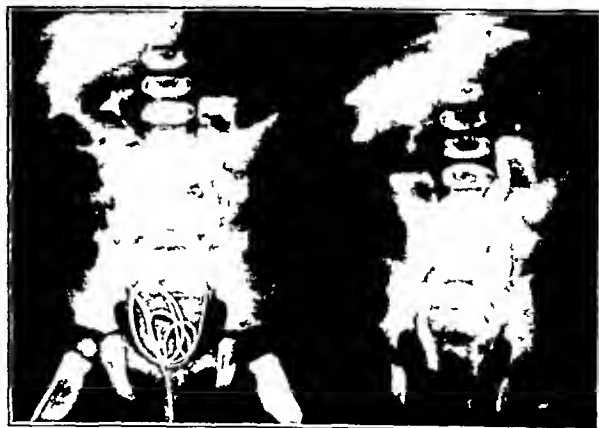

Fig 2—Retrograde urograms of a girl 16 months old with achalasia at the ureterovesical juncture. The ureterectasis is out of proportion to the pelvic dilatation although there are some beginning elongation, tortuosity and pyelectasis on the right.

contraction above accompanied by relaxation below, is disturbed. When the peristaltic wave reaches the intravesical ureter there is an absence of active relaxa-

tion, or opening, and the inert musculature resists ureteral emptying, although probably to a lesser degree than in the mechanical obstructions. As a result there are increased peristaltic activity, muscular hypertrophy, dilatation, stasis and, finally, atony. The onset of infections may hasten these changes and with inflammatory infiltration of the ureter and at the uretero-

Fig. 3 (case 2)—Hydronephrosis on the right side without obstruction in a boy 4 years old. The incomplete injection fails to show the marked dilatation of the entire ureter found at operation.

vesical junction produce secondary obstructive factors which modify the clinical picture and obscure the primary etiology. Whether this dysfunction is the result of abnormal impulses through the hypogastric nerves or whether it is entirely intrinsic is not known.

DIAGNOSIS

The recognition of these functional imbalances is based on a careful exclusion of the commoner and better known lesions, together with positive manifesta-

Criteria for Diagnosis of Ureterovesical Achalasia

A Negative

- 1 Absence of any nervous lesion either central or peripheral involving the lower part of the tract
- 2 Absence of mechanical obstruction at the vesical outlet or posterior urethra
- 3 Absence of stenosis, spasm or incontinence (regurgitant orifice) at the ureterovesical junction

B Positive

- 1 Relaxed easily catheterized ureteral orifice
- 2 Absence of tone about the ureterovesical orifice and in the juxta ureteral trigon
- 3 Disturbance in ureteral dynamics as evidenced on ureteral meatoscopy
- 4 Character of dilatation of the upper part of the tract

tions which are suggestive. In the early or uncomplicated stages the signs are fairly conclusive, but with the development of secondary changes the border line between the functional and the mechanical is less clearly defined. The criteria enumerated in the accompanying table permitted a diagnosis of achalasia of the ureterovesical junction in four cases of varying degrees of ureteral and pelvic dilatation in children.

Neurogenic vesical dysfunctions and mechanical obstructions at the vesical outlet and in the posterior urethra were ruled out by neurologic examination and the absence of urinary symptoms and the cystoscopic and cystographic changes characteristic of these conditions. One child had had myotonia congenita of the flaccid type which was evidently not true Oppenheim's disease because he had fully recovered. He did have marked strabismus, speech defect and other evidences

of nervous instability, but no urinary symptoms or signs of dysfunction of the bladder.

Because of the frequency with which obstructions at the vesical outlet and posterior part of the urethra are overlooked, extreme care was taken to rule out contracture, bars and valves in this region. Cystograms were normal and residual urine was absent in all cases. The absence of obstruction was confirmed by an open operation in one.

Likewise, there was no stenosis, either spastic or organic, or incontinence (regurgitant orifice) at the ureterovesical junction. Catheters and bulbs could be passed easily, and ureteral reflux on cystography was absent. There was no spasm or imbalance of the first type. On the contrary, in three cases there were flabbiness and lack of tone about the ureteral orifice and in the juxta-ureteral trigon. This was an impression gained from its relaxed appearance and the ease with which the orifice could be stretched and the ureteral mound moved about by manipulation of the catheter. On ureteral meatoscopy after the injection of indigo carmine, it was noted that the expulsive action was sluggish and the urine appeared to seep through the immobile and apparently closed orifice. The contraction and subsequent relaxation were weak or absent.

The gaping rigid golf hole type of orifice with vesico-ureteral regurgitation, which is considered by the French as characteristic of nonobstructive dilatations, was not found. It is more apt to be present with obstruction in the lower part of the tract, either mechanical or neurogenic and associated with maturational changes. Even if no obvious obstruction is

Fig. 4 (case 2)—Megalocolon in a boy 4 years old who had megaloureter on the right side without obstruction.

present the cystographic evidence of chronic retention by the bladder, such as dilatation, irregular outline with cellules, and vesico-ureteral reflux rules out functional imbalances of the ureter (fig. 1).

Ureterectasis out of proportion to the pelvic dilatation with comparatively little elongation and tortuosity is supposed to be characteristic of nonobstructive lesions (fig. 2). At times it occurs also with low

mechanical obstruction and may simply represent a stage of compensation in which the ureteral changes have so far protected the pelvis

REPORT OF CASES

CASE 1—A girl 16 months old had had pyelonephritis for several months. The acute symptoms responded to the standard methods of treatment, but the pyuria persisted. A general physical examination showed no gross abnormalities.

Cystoscopically no obstruction in the urethra or at the vesical outlet was seen. There was no residual urine and the cystogram was normal, showing no ureteral reflux. The ureteral orifices were not gaping but two No. 4 French catheters could be passed easily on each side. The ureteral mounds were flabby, and the ureteral orifices could be stretched widely and moved about by manipulation of the catheters. Expulsive action was sluggish, with absence of brisk opening of the meatus, and the urinary jet was weak. The separate functions of the kidney were equal and good. Retrograde urograms (fig. 2) showed bilateral ureterectasis more marked on the right, with some early dilatation of the right pelvis. There was evidently a beginning break in compensation on the right with secondary obstructive factors, elongation and kinking near the ureteropelvic junction.

After the ureteral catheterization the pyuria cleared up. The referring physician on the assumption that if a neuromuscular dysfunction was present it must be a spasm gave atropine in daily doses of one fortieth grain (15 mg). The pyuria returned and has resisted all internal medication. A presacral neurectomy was recommended but refused.

The observations in this case fulfilled all the standards previously enumerated for a diagnosis of achalasia and the condition was regarded as typical in all respects of a neuromuscular dysfunction of that type.

CASE 2—A boy 4 years old complained of abdominal discomfort and distention. The persistent observation of a few pus and blood cells in the urine and tenderness in the right lumbar region led to a renal study, in which hydronephrosis on the right side was found apparently caused by obstruction at the ureteropelvic junction (fig. 3).

There was no obstruction in the lower part of the tract or at the ureterovesical junction. Because of advanced hydronephrotic atrophy, a nephrectomy was advised. At operation it was evident that the urogram had been misinterpreted because of the obviously poor and incomplete injection. Grossly and histologically there was no obstruction at the ureteropelvic junction, but the ureter was markedly dilated throughout its entire length. In the absence of any obstruction the possibility of functional imbalance of the lower ureter was considered.

Because of persistent obstipation and postoperative abdominal distention a barium sulfate enema was given which showed typical Hirschsprung's disease (fig. 4).

It is now generally accepted that the dilated esophagus of cardiospasm and the dilated bowel in megacolon or Hirschsprung's disease are the result of achalasia of their respective sphincters, the cardiac and anal or pelvic rectal. Successive stages of compensation with hypertrophy of the muscle and dilatation followed by decompensation with atony and atrophy have been observed. Craik⁶ in 1923 called attention to the analogy of megalo-ureter and megacolon and considered them both to be primary congenital dilatations. Hurst⁷ in 1931 was the first to emphasize that in some cases megalo-ureter might be secondary to achalasia at the ureterovesical junction, and there is increasing evidence to support his contention.

Other authors (Marchand, Gerner, Rath Roy, Ishikawa and Schmidt⁸) have observed nonobstructive dilatation of the urinary tract associated with Hirsch-

sprung's disease. Lehmann⁸ reported megacolon in a baby, aged 4 years with bilateral hydronephrosis without mechanical obstruction and with marked hypertrophy of the ureteral walls. Still and Thompson⁵ and Priesel⁸ have seen megalo-esophagus with hydro-ureteronephrosis. These observations have led some persons to the conclusion that achalasia is a systemic disease of the sphincters with smooth musculature. The majority are of the opinion, however, that it is a local condition and in the urinary tract may be unilateral or bilateral.

The association in this boy of megalo-ureter and megacolon may be entirely coincidental. However, recent studies at least suggest that the two conditions may be the result of a response to the same type of

Fig. 5—Advanced ureterohydronephrosis on the left side and a functionless right kidney following deep diathermic incision at both ureterovesical junctions for achalasia. The subsequent scarring and contraction converted an apparent functional disturbance into a mechanical obstruction.

etiologic factor. A lumbar sympathectomy was followed by marked improvement in function of the bowel.

TREATMENT

The indications for treatment of a condition so little understood and concerning which there have been so little clinical data are not clearly defined.

In the case of functional imbalance of an organ whose nerve supply is entirely from the autonomic system attention would of course be directed to the possibility of correction through surgical treatment of the sympathetics. However, knowledge is incomplete as to nervous control of ureteral activity, the direct pathways of the inhibitor or augmentor impulses, which impulse predominates to produce the dysfunction and how their balance can be modified. In a number of cases of nonobstructive hydro-ureter it has been clearly shown that presacral neurectomy has resulted in improved ureteral drainage and disappearance of the dilatation.⁴ R. Ogier Ward⁹ reported a case and attributed the striking results to the fact that the ureters were freed of abnormal hypogastric impulses.

⁸ Quoted by Rizzzi.

allowing them to act by the contractile powers which are essentially inherent in all unstriated muscles

Hypogastric overactivity is known to produce spasm at the ureterovesical juncture, but just what abnormal impulse is responsible for the dysfunction without spasm, the dissynchronism of achalasia, is not known. Further studies may show whether the disturbance is intrinsic, peripheral or central and the effect of hypogastric section. Experience may prove hypogastric section to be the method of choice in the treatment of all types of functional imbalance of the lower part of the ureter.

Attempts have been made to overcome the obstruction of the inert sphincter and improve drainage by operation on the intramural ureter. Thomson-Walker² in 1928 did a plastic resection in a case of megalo-ureter attributed to achalasia, enlarging the opening and sewing the ureteral mucosa to that of the bladder. Clinical cure was reported, but no follow-up as to the effect on the dilatation.

Incisions of the junction by the high frequency knife have been reported. To be effective, the incision must not be limited to the mucosal valve but must include the entire thickness of the intramural ureter. This procedure was followed in one of my cases.

In a boy of 4 years with bilateral ureterohydronephrosis without obstruction, a suprapubic cystotomy was done to confirm the absence of obstruction of the vesical neck and permit deep diathermic incision of both ureterovesical junctions. Despite repeated cystoscopic dilatations, scarring and contraction produced resistant fibrosis and converted an apparent functional disturbance into a mechanical obstruction. After three years the right kidney was functionless and there was advanced hydronephrotic atrophy on the left (fig. 5).

Hurst⁷ recommended gradual dilation of high degree. Rizzi⁵ suggested forcible dilation or avulsion in preference to plastic resection or incision, as less likely to result in orifices that are regurgitant.

With persistent infection, ureteral dilation, the use of an indwelling ureteral catheter, pelvic lavage and other accepted methods are indicated. With decompensation and secondary obstruction and infection, the indications for nephro-ureterectomy are the same as with the obstructive lesions.

SUMMARY AND CONCLUSIONS

Two types of functional imbalance at the ureterovesical junction are recognized: (1) increased tonicity, or spasm, and (2) absence of the usual active relaxation synchronous with the termination of ureteral peristalsis, or achalasia.

The resistance to ureteral emptying caused by these dysfunctions sets in motion the same physical and dynamic factors which produce dilatation in the mechanical obstructions. Compensation is more apt to occur in the functional imbalances than in the mechanical obstructions, because resistance to ureteral emptying is apt to be less unyielding, hence the observation of ureterectasis out of proportion to the pelvic dilatation and the absence of elongation and tortuosity.

In some cases, congenital idiopathic dilatation considered as a primary embryologic developmental defect may in fact be secondary to a segmental imbalance or abnormal activity of the sphincter.

The association of megacolon and megalo-ureter in one child is of interest in view of the contention that the mechanism of their pathogenesis is similar.

PRIMARY MALIGNANT TUMORS OF THE UROGENITAL TRACT IN INFANTS AND CHILDREN

MEREDITH F. CAMPBELL, M.D.
NEW YORK

Although the incidence of primary malignant tumors of the urogenital tract in the young is comparatively low, the extremely high mortality induced by these lesions makes them a problem of grave clinical concern. Renal neoplasms are far the most frequent of these tumors and merit corresponding attention. Yet the scope of the subject and the limitations of space scarcely permit me to hope that the present discussion will more than direct attention to the newer methods of diagnosis and treatment. In short, the only prospect for lessening the extremely high mortality of these lesions lies in (1) earlier diagnosis by urography, aspiration biopsy or hormone tests (Aschheim-Zondek), as indicated in a particular case, together with (2) intensive preoperative and postoperative radiation therapy by the fractional dose method (Coutard). The data here presented are based on the clinical and/or pathologic study in seventy-seven cases of primary malignant urologic disease in infants and children between the ages of 3 days and 9 years.

TUMORS OF THE KIDNEY

I could find but two reported instances of carcinoma in children (Philip and Salin,¹ Cathcart²).

Hypernephroma accounts for from 2³ to 11⁴ per cent of malignant renal tumors in children and appears to be more common in girls. Recent studies of hypernephroid tumors by biologic assay have shown a content of cortical hormone (adrenal cortex extract) comparable in amount to that found in the normal adrenal.⁶ These studies, together with such symptoms as fever, pigmentation of the skin and changes in blood volume,⁶ tend to support the Grawitz theory of adrenal cell rests as the origin of these tumors. Hypernephroma metastasizes by the lymphatics, blood stream and direct extension, the lungs and the long bones are most apt to be involved. In a fifth of the patients, metastases exist when the patient first presents himself. Hematuria is the dominant early symptom of hypernephroma in children, quite in contrast to the initial symptom of a mass in the loin such as occurs in Wilms' tumor. Sometimes the passage of large blood clots produces renal colic, but otherwise pain in the loin is due chiefly to distention of the renal capsule by the growth. When the diagnosis is made early and prompt nephrectomy follows, the prognosis is slightly better than for Wilms' tumor. Hematuria or a mass in the region of the kidney will direct attention to the urinary tract, but the diagnosis will rest chiefly on retrograde pyelography. The results of irradiation are not as phenomenal

in patients with hypernephroma as in those with Wilms' tumor, yet such therapy may advisedly be employed both preoperatively and postoperatively. Chief reliance must be placed on early diagnosis and nephrectomy.

Embryonal adenomyosarcoma (congenital mixed tumor, Wilms' tumor) is the commonest neoplasm of the urinary tract and abdomen in the young, in whom it constitutes about a fifth of all tumors. Because of the heterogeneous histology of these embryonal growths, they have been variously described as adenosarcoma, embryonal sarcoma, myxosarcoma, chondromyxosarcoma, rhabdosarcoma, rhabdomyoma and lipomyoma. Seventy-five per cent of Wilms' tumors appear before the fifth year, and two thirds appear before the third year, which is the average age at which the tumors are first recognized. These growths have been observed in the fetus, I have seen one in an infant aged 3 days and have performed nephrectomy on an infant aged 6 weeks. After the seventh year hypernephroma is more apt to occur than embryonal adenomyosarcoma. Statistics suggest that the tumor has a slight predilection for the left side and for males.

The embryologic etiology has been admirably discussed by others, suffice it to note here that the genesis of these tumors is satisfactorily explained only on embryologic grounds. The prevailing theories (of Ribbert,⁷ Wilms,⁸ Birch-Hirschfeld,⁹ Ewing,¹⁰ Muus¹¹ and Dean and Pack¹²) vary chiefly in the hypothecated time at which the embryonal tumor anlage develops. Dean and Pack expressed the belief that the nature of the tumor indicates the period of formation of tumor anlage. Thus tumors characterized by primitive renal tubules and glomeruli originate at the stage of blastema or nephrotome, but most renal tumors found in children show such varied structure that these writers explained their origin at an earlier period, i.e., before the urogenital ridge which contains the multipotent cells has formed the nephrotome.

The size, rate of growth and weight of the Wilms tumor vary greatly, the growth may account for half of the body weight. Enlargement of the tumor frequently produces compression symptoms, especially of the bowel. In an 18 months old boy with a large Wilms' tumor on the left side, the distal two thirds of the compressed pancreas resembled the tongue in a shoe.

On section Wilms' tumors may be soft, brainlike, gelatinous, grumous, semitranslucent, edematous or fibrous, with or without cystic areas, grayish pink, grayish yellow or white, and areas of hemorrhage or necrosis may be seen. A fifth of the patients show metastases. The spread is characteristically through the blood stream, yet by lymphatic or direct extension the liver, spleen, spine, intestine, diaphragm and lungs may be invaded. Less frequently the skull, brain, scapula, ileum, abdominal and lumbar muscles and even the corpora cavernosa have been the site of metastases. With extrarenal extension, the retroperitoneal lymph nodes are usually involved. Metastases were found in fifteen of thirty-seven cases of renal tumor observed

in hospitals¹³ with which I am or was formerly associated, in fifteen additional cases in this series the presence or absence of metastases was not recorded.

Microscopically these tumors show a variety and complexity of structure, striped and unstriped muscle, elastic fibers, cartilage, bone, adipose tissue and mucoid stroma, all of which are normally foreign to the renal parenchyma, are commonly described. Tubular structure is sometimes seen and even abortive attempts at glomerular formation. In rapidly growing tumors the fragile capillaries rupture easily to produce intratumoral hemorrhage. In one of my patients, an 18 months old boy, an enormous renal tumor appeared overnight, the specimen showed widespread fresh hemorrhage in the center of the growth. Thus, the observation of sudden enlargement of renal or testicular neoplasms suggests hemorrhage into the growth.

Symptoms—A tumor in the region of the kidney is the usual early symptom of Wilms' tumor and is generally noted accidentally by the parent or the nurse. In one case a 4 year old boy first called attention to his renal neoplasm. As the growth enlarges the child becomes pot bellied. Compression by the enlarging tumor may produce marked gastro-intestinal respiratory or cardiac disturbances, with vomiting, jaundice, anorexia, cachexia, anemia, dilatation of the superficial abdominal veins, cutaneous petechiae, varicocele, diarrhea, constipation, cyanosis or pleural effusion. In a 13 months old boy I operated on at the Babies Hospital, a large renal rhabdomyosarcoma on the left side produced a fair sized varicocele on the same side, which disappeared after nephrectomy.

Pain occurs with about 35 per cent of Wilms' tumors and results principally from capsular tension consequent to the enlarging parenchymal growth. Pain due to mass weight and abdominal pressure is also frequent. Hematuria does not occur until late and in only about 15 per cent of cases, quite in contrast to its high incidence in renal hypernephroma. Pyuria and disturbances of urination have been noted in from a third to a fourth of the cases. Half of all patients with renal neoplasm have fever, which may be high continuous, low continuous, or low remittent and may appear early in the course of the disease or terminally. The mechanism of this reaction is not understood, but it is observed in children who have other types of malignant neoplasm, such as lymphosarcoma or endothelial myeloma.

Diagnosis—This is strongly suggested by palpation of a mass in the renal area. A renal tumor grows forward, a protruding mass in the posterior iliocostal space rules out renal neoplasm and suggests neuroblastoma of the adrenal. Intravenous or excretory urographic studies may suffice to make the diagnosis, but interference with the renal function by the tumor often prevents the obtaining of a satisfactory excretory urogram. Yet the method will assist one in determining that the opposite kidney is sound. This is of vital interest, especially when nephrectomy offers hope of cure. Nevertheless, only a retrograde pyelogram can be relied on for a clear urographic demonstration of the pelvis of a tumor-bearing kidney in a child. Because the problem is one of life and death and because retrograde pyelography can be performed with

negligible risk, the positive diagnosis should rest on data obtained by this method. In renal tumor the pelvis may be completely obliterated, but as a rule the diagnosis rests on urographic demonstration of the bizarre changes in pelvic conformation consequent to (1) mechanical distortion of the pelvis by the new growth, (2) obstruction of the upper part of the ureter or the pelvic outlet and (3) ulceration resulting from infection or necrosis. In performing the urologic examination it is most important to determine that the better kidney is able to support life. Moreover, at the time of examination it is equally important to determine the existence of metastases—by abdominal and cervical palpation as well as by roentgenography of the chest.

Differential Diagnosis—The conditions from which renal tumor must be differentiated are chiefly adrenal tumor, hydronephrosis, solitary cyst, congenital polycystic disease, extrarenal mass or tumor, Hodgkin's disease, hepatic or ovarian tumor, splenic, fecal, intestinal or pancreatic tumor, mesenteric or retroperitoneal cyst, tuberculous peritonitis and perirenal abscess. Of these, neuroblastoma of the adrenal and hydronephrosis merit most consideration. According to my experience, tumors of the adrenal occur a third as often in children as tumors of the kidney, and the urographic demonstration of a kidney compressed well downward and showing marked pelvic distortion is at least suggestive of adrenal tumor. Yet the tumor may be simply a massive one of the upper portion of the kidney. On the other hand, in a boy of 10 months referred for examination because of "renal tumor," the growth was found to be a neuroblastoma springing from the left sympathetic chain at the level of the fourth lumbar vertebra. The tumor mass was approximately 12 cm in diameter and by urography was demonstrated to push the kidney upward. Hydronephrosis is doubtless the commonest abdominal tumor in children and when simulating renal neoplasm usually results from ureteropelvic obstruction, either congenital stricture at the ureteropelvic junction or vascular obstruction of the ureter at the pelvic outlet. The pyelogram should make the differential diagnosis evident.

Aspiration Biopsy—If there is still doubt as to the diagnosis, an aspiration biopsy may be performed. The center of the tumor mass is determined by triangulation from a study of the urogram, and into this central area an 18 gage needle attached to a 5 or 10 cc syringe is plunged. Moderate suction is applied as the needle is introduced, and when it is at the desired depth the suction is increased sufficiently to draw out tissue for microscopic examination. At the Memorial Hospital for the Treatment of Cancer and Allied Diseases this diagnostic procedure has not been observed to influence adversely the subsequent clinical course.¹⁴

Prognosis—When the usual surgical treatment of nephrectomy only is employed the mortality is about 95 per cent. Only five of fifty-five patients lived longer than one year, a mortality of 91 per cent. The average life expectancy following nephrectomy alone is eight months; recurrences are usually found after four months. A child surviving a year without evident metastases is probably cured. These figures consistently stand in all the larger series of cases reported. Nor will this mortality be reduced without the employment of intensive preoperative and postoperative radiation therapy.

Treatment—Radiation Therapy The therapeutic results consequent to the greatly increased tissue dose which it is possible to obtain by the multiple (dark) fractional dose method¹⁵ should be more widely appreciated. In fact, at the Memorial Hospital in New York recent observations on radiation therapy in the treatment of testicular tumor (which closely simulates biologically the activity of Wilms' tumor) have shown that a fourth (29 per cent) of the inoperable tumors were apparently cured by this means alone.¹⁶ Moreover, the development of and improvement in radiation therapy as applied to urogenital neoplasm constitute one of the major recent advances in urologic therapeutics. The technical details of the therapy should be entrusted to a competent radiologist. Here only the generalities can be indicated. As a rule portals 9 or 10 cm in diameter are large enough for the treatment of renal tumors in children. Anteroposterior, postero-anterior and lateral exposures should cover not only the known tumor-bearing area but the lower part of the abdomen, the chest and the mediastinum if they are known to contain metastases. A total dose of from 1,200 to 1,500 roentgens to each portal may be equally divided into daily doses (usually except Sunday) for three or four weeks. In the employment of radiation in treatment of the young, due caution must be observed, and vital organs, such as the liver, spleen and opposite kidney, must be protected. Reduction of the dose or even temporary cessation of treatment may be demanded by reactions—febrile hematopoietic (anemia, leukopenia) or gastro-intestinal (nausea, vomiting, diarrhea). If the child stands the treatment well, the total dose can be increased or the therapeutic period prolonged, but in any event the young patient must be closely watched, the intensity of the local cutaneous reaction, the regression of the tumor and the general tolerance being noted especially.

Operation (Nephrectomy) After the preoperative irradiation the optimum time for operation appears to be from three to six weeks. With irradiation the tumor becomes markedly reduced in size, but if nephrectomy is not performed within six weeks it recurs, and growths which follow irradiation are less radiosensitive than the original growth, they may even become irradiation fast and the opportunity for cure may be lost.

The advisability of nephrectomy in the presence of metastases merits consideration. Although fully aware of the usual hopeless prognosis when metastases have developed, I am led by the excellent results which have been obtained by well planned irradiation in the treatment of teratoid tumors of the testicle to give every child with Wilms' tumor the benefit of irradiation and nephrectomy even though metastases are known to exist. In short, only by treating the many will one cure the few.

Postoperative Irradiation Beginning three or four weeks after removal of the tumor a course of irradiation similar to the preoperative course and including irradiation of the metastases is employed. As a rule, if cure is to be achieved it will result from the treatment already outlined. Yet if the child will tolerate it, a second postoperative course of irradiation for therapeutic fortification may be given six weeks after

completion of the first, and a second course must be employed when there is evidence of recurrence of the tumor or metastasis.

The following case illustrates the use of the method described.

In a boy of 13 months a Wilms tumor estimated to be 10 by 10 by 15 cm in size was demonstrated in the left loin. Preoperative irradiation reduced the growth to slightly larger than the size of a normal kidney, a total of 4,500 roentgens was given anteroposteriorly, postero anteriorly and laterally in divided doses daily except Sunday for two weeks. Despite the child's tender age there was no unfavorable reaction to the irradiation, and three weeks after the last exposure nephrectomy was performed. No local metastases were observed at operation, and the postoperative course was uneventful. Postoperative irradiation by divided daily doses was begun three weeks after nephrectomy, a total of 2800 roentgens being given in ten days. The child was apparently cured fifteen months later, abdominal examination with anesthesia revealed no evidence of recurrence, and roentgenograms of the chest were normal.

In the case of Wilms' tumor, failure of recurrence in six months materially improves the prognosis (q v), for the average life expectancy following the initial discovery of the tumor is eight months.

Yet not all children do as well as this boy. For example, in a 5 year old girl with a comparable Wilms tumor on the left side, who was subjected to similar treatment, a profound reaction (febrile and gastrointestinal) to the irradiation required cessation of radiotherapy after 1,210 roentgens had been given. Operation disclosed local and intraperitoneal metastases. Tumor-bearing regional lymph nodes appeared caseous (irradiation necrosis). The child died of tumor four months after nephrectomy and an aborted attempt to give postoperative irradiation. Here an extensive lesion plus hypersusceptibility to irradiation defeated treatment.

Age is no contraindication to nephrectomy. Deming¹⁷ performed this operation on an infant aged 29 days, and I have on an infant aged 6 weeks. The latter patient is of special interest because of her age and because apparently she is one of the relatively few who have been cured.

In a 5 weeks old girl referred by Dr Charles Gilmore Kerley, a mass was first noted in the right loin at the age of 3 weeks. A complete urologic examination was carried out at 5 weeks. The diagnosis of Wilms' tumor was made, and at 6 weeks nephrectomy was performed. An embryonal adenomyosarcoma weighing 500 Gm was removed. The child was apparently cured three years later. In this case the question of preoperative irradiation was seriously considered, but two radiologic consultants advised against it in view of the child's extreme youth.

In a boy of 13 months an enormous rhabdomyosarcoma of the right kidney was removed. On section the gross appearance strongly resembled that of uterine fibroids. The boy was alive and well four years later. Except for these three apparently cured patients and two additional patients operated on by others, all fifty-five children with malignant renal tumor died.

Tumors of the renal fibrous capsule are extremely rare. Three fourths of the ninety-two reported cases were in girls, and most of the patients were under 10 years of age. These lesions are predominantly sarcomatous and are likely to be correctly recognized only at operation or by histologic examination.

Tumors of the renal pelvis are so scarce in children as to merit scant clinical consideration, Perlmann¹⁸ reported a case of pelvic epithelioma in a child of 3 years.

Tumors of the ureter in children are almost exclusively secondary to renal tumors and even so are seldom seen.

TUMORS OF THE BLADDER

Tumors of the bladder are most unusual in children and are predominantly of mesodermal origin, papilloma has been reported, but no undisputed instance of carcinoma. In 1924 Deming¹⁹ found but sixty-four authentic cases, to which he added two, I know of some ten cases which have occurred since that time, three of which are unreported. More than half of tumors of the bladder in children are sarcomas, a few are myxomas and the remainder are fibroids, polyps, rhabdomas, dermoids, myomas or papillomas.

The symptoms of tumor of the bladder are consequent to obstruction or neoplastic ulceration. Thus there are dysuria, frequency, often burning and hematuria, and, with infection, the urine is cloudy with pus. A palpable vesical mass may be either the growth itself or the result of complete urinary retention consequent to tumorous obstruction. During the past year, at Bellevue Hospital myxosarcoma arising from the floor of the bladder was observed at autopsy in a 4 year old boy.

The diagnosis of vesical tumor is made by cystoscopy, but to date no case has been recognized sufficiently early to justify radical treatment. Cystography may show a filling defect caused by the growth.

Treatment—It is possible that satisfactory results may some day be obtained by (1) the employment of a modification of the Coutard therapeutic method of irradiation, (2) direct interstitial irradiation by radon implantation or (3) ureterosigmoidostomy followed by total cystectomy. Because of the extremely high malignancy of tumors of the bladder and the consequent radiosensitivity, it would seem that the best results might be expected from irradiation alone or at least from combined radiation and surgical therapy.

TUMORS OF THE PENIS AND THE URETHRA

Malignant growths of the penis and the urethra are almost unknown in the young. Urethral polyps are not uncommon in children and merit consideration because they may produce obstruction and may be precancerous lesions. In a 6 year old boy subjected to urologic examination because of persistent enuresis, a pedunculated tumor 12 mm in diameter, fastened by a broad pedicle 1 cm long, was found to spring from the roof of the posterior part of the urethra directly above the verumontanum, to pass back into the outlet from the bladder, where it produced a ball valve obstruction. The growth was removed through the opened bladder.

Rhabdomyoma and carcinoma of the scrotum in children have been described. I saw an extensive hemangioma of the left side of the scrotum in a 6 months old boy, consent for treatment was refused. Radical excision is the usual indicated therapy, although freezing with carbon dioxide snow or irradiation (with testicles protected) may be employed.

TUMOR OF THE TESTICLE

Approximately 150 cases of tumor of the testicle in children have been reported, I have seen the condition but once, in a 13 months old boy. Of over 300 patients treated by Dean¹⁶ for teratoma of the testis, only two were boys 3 and 4 years of age. There is no predilection for one side or the other. Examination of the growths shows them to be of congenital or embryonal origin, they have been observed at birth. According to Dean the cryptorchid testicle is 200 times as likely to become malignant as the normally situated organ.

Testicular tumors are now generally classified as embryoma and seminoma. The embryonal tumor is the one characteristically seen in children and commonly presents structures indicative of a tridermal origin, practically every tissue of the body may be represented in a single tumor. Seminoma—a tumor presumed to be derived from cells of the spermatogenic system—is practically unknown in the young. Rare instances of adrenal rests as a site of malignant testicular tumor have been reported, as have dermoid cysts within or attached to the testicle. Testicular tumors metastasize early and widely, at first through the lymphatics to the iliac and the lower lumbar muscles, with subsequent vascular invasion and hematogenous spread to distant structures such as the liver, brain, lungs or bones. Enlargement of the testicle is the earliest manifestation, but by the time this is noticed an abdominal metastatic mass may exist. Growth of the tumor is rapid, and in a few months the classic sequence of testicular tumor, visceral metastases and death, occurs.

Diagnosis—The correct diagnosis is suggested by palpation of a hard or enlarged nodular testis. In palpating the enlarged testicle one should avoid squeezing, especially when tumor is suspected, lest malignant cells be forced into the circulation. Abdominal palpation for metastases should not be neglected, cervical or cranial metastatic nodules may also be palpated.

Hydrocele, spermatocele, testicular contusion, tuberculous, syphilis, hernia or congenital cyst of the scrotum must be considered in the differential diagnosis. Not only can these various conditions usually be ruled out by physical examination, but a modified Aschheim-Zondek test for the identification of testicular tumors performed under most sensitive conditions (with white mice) will almost always correctly identify the malignant lesion.²⁰ Most testicular tumors provoke the elaboration of the follicle-ripening hormone of the anterior pituitary gland which is eliminated in the urine. By the injection of this urine into young virgin mice, the estrual cycle is induced. Finally, should the diagnosis still remain dubious, aspiration biopsy will enable one to identify a malignant growth.

Prognosis—This is always bad, and only by the employment of the method outlined in the following paragraph can one hope to reduce the high mortality which now generally exists. By this method the usual mortality for adults, 95 per cent, has been reduced at the Memorial Hospital to 14 per cent for patients in whom the tumor is operable, and 29 per cent of the patients in whom the tumor was inoperable were apparently cured by irradiation alone.¹⁷

Treatment—The fundamentals of treatment of testicular growths in boys are those which have been described for the treatment of renal tumor. Intensive

preoperative (orchidectomy) and postoperative irradiation given by the divided dose method and applied to the local growth (500 roentgens), isolaterally to the abdomen and to pulmonary or other metastases if they are known to exist. When the testicular tumor has diminished it may be removed with local anesthesia, but, as indicated in the preceding paragraph, in over a fourth of adults with inoperable testicular tumor Dean obtained apparent cure by radiation therapy alone.¹⁶

The technic and the amount of radiation therapy are usually best determined by a skilled radiologist. Dean recommended the following treatment for a child with primary tumor of the testicle and without demonstrable metastases:²¹

Assuming a primary tumor 4 by 4 cm in size, use high voltage roentgen rays at a distance of 50 cm and with a portal of 6 by 6 cm. Protecting the opposite testis as well as possible with leaded rubber, give 500 roentgens to the tumor. This dose is twice repeated with a day intervening between treatments. Measurements should be taken at short intervals, and in from two to four weeks, or when the testicle has regressed to approximately normal size, an orchidectomy should be performed.

Whether or not metastases are palpable in the pelvis or abdomen, these areas should be treated. I would use four portals, the lower and the upper part of the abdomen, anterior and posterior, on the same side as the tumor. Two hundred and fifty roentgens should be given each portal. Two portals should be treated daily—those opposite each other. By this is meant that the lower abdominal portals, anterior and posterior should both be treated the same day with 250 roentgens until from 2,100 to 2,400 roentgens has been given each portal (i.e., eight or nine exposures each). The upper abdominal portals, front and back, should be similarly given the same total dose. It is notable that a day of rest should be allowed between the treatments of each portal, i.e., the lower abdominal portal should be treated one day and the upper abdominal the next. The size of the portals, of course, depends on the size of the patient, but treatment should be given from the testis up to and including the part of the epigastrium which underlies the xiphoid process, and the treatment should extend at least an inch beyond the midline.

Perhaps two or three of these cycles would suffice but no definite statement can be made concerning this point. Whether or not further treatment is given depends entirely on the response of the patient, the condition of the skin and other observations of the urologist.

It must be emphasized that the general condition of the patient must be carefully watched and that close observation must be made of the condition of the blood, especially the white cells.

An illustrative case has been reported by Dean. A boy of 4 years had a hard, rapidly growing swelling on the left side of the scrotum for six weeks. Orchidectomy revealed a spindle cell sarcoma. When he was admitted to the Memorial Hospital, a pea-sized tumor was found near the lower end of the operative scar. The scrotum, groin and left part of the abdomen were heavily irradiated with the radium pack. The nodule soon disappeared, the boy was well fourteen years after treatment.

Tumors of the tunica vaginalis, epididymis and spermatic cord are uncommon and frequently benign, malignant growths are usually sarcomatous.

TUMORS OF THE PROSTATE

Tumors of the prostate are extremely rare and in children are almost exclusively sarcomatous. Symptoms are those of urinary obstruction, often with hematuria, and ultimately chronic complete retention. The

²¹ Dean A. L. Jr. Personal communication to the author.

diagnosis is made by urologic examination, in which the rectal examination reveals a large mass filling the prostatic region and sometimes compressing the bowel. The mass may be firm or semifluctuant. It is notable that in most of the reported cases of prostatic sarcoma the surgeon operated after an erroneous diagnosis of prostatic abscess had been made. To date the outcome has been uniformly fatal. Only by early recognition and radical treatment is there a chance for cure. Radiation is of palliative value. I have seen but three cases, in boys 4, 17 and 18 years old, respectively.

The 4 year old boy, referred by Dr Harry Morton and first seen Oct 15, 1936, had had urologic symptoms for six weeks. There had been rapidly increasing dysuria for two weeks and acute retention for the past month, during most of which time an indwelling catheter had been employed. Rectal examination disclosed a slightly irregular firm, fixed mass, about 10 by 10 cm, filling the prostatic and vesical region. Cystoscopy showed multilobular intusion of the tumor at the neck of the bladder and over the trigon. Suprapubic cystotomy was performed to establish permanent drainage of the bladder. Through the open bladder two pieces of tissue approximately 1.5 cm in diameter, translucent and closely resembling thick yellow gelatin, were enucleated from the prostatic mass. Histologic examination showed myxoliposarcoma (Ewing). Intensive radiation therapy daily except Sunday, 157 roentgens a day (3,200 roentgens in three weeks) applied to the prostate anteroposteriorly, antero-obliquely, postero-anteriorly and twice perineally, reduced the tumor two thirds in size. There was practically no irradiation sickness. One month after the completion of the first course a similar course of irradiation was given. The tumor diminished still further, and free voiding permitted the suprapubic tube to be clamped off, I do not dare remove it. It seems unlikely that benefit in this case is more than transitory, yet irradiation offers the only hope.^{21a} The case is here recorded (1) to illustrate the beneficial effects of radiation therapy and (2) because it is unique or at least one of the very few cases of prostatic sarcoma in a child to be treated by irradiation.

TUMORS OF THE ADRENAL

Embryologically and endocrinologically the adrenal must be considered as intimately related to the urogenital tract. Benign adrenal tumors are occasionally seen post mortem in the young but are seldom encountered clinically except in rare instances of cortical or subcortical growth in which development of the genital tract and sexual precocity are striking manifestations. The important malignant adrenal tumor in children is the neuroblastoma or neurocytoma, and according to my observation it occurs fully a third as often as malignant renal tumors. Histologically the neuroblastoma is composed of embryonal nerve cells and fibrils. The latter are often arranged in rosettes, sometimes in longitudinal bundles. The metastases generally simulate the primary growth, but round cells predominate.

Neuroblastomas grow rapidly and not only push the kidney down but are likely to protrude posteriorly—a point differentiating them from renal tumors. The growths metastasize rapidly, principally through the lymphatics. Various types of metastatic tendencies have given rise to clinical designations such as (1) a variety showing extensive hepatic metastases (Pepper²²), (2)

a type characterized by extensive metastases to the skull and the orbit (Hutchison²³) and (3) a form showing only a local enormous central interrenal or midabdominal mass.

The diagnosis will most often be made at the operating table, although the urographic characteristics of adrenal tumor, as described in the paragraph on the differential diagnosis of renal tumor, may enable the clinician to recognize the condition preoperatively. It is possible that periadrenal pneumography²⁴ may eventually prove of as much diagnostic value for children as it has for adults with adrenal enlargements.

Treatment—Removal of the growth is the treatment, but in the case of adrenal tumor, too, preoperative and postoperative intensive radiation therapy by the divided dose method, as previously described, appears to offer the only hope for the reduction of the extremely high mortality. Rarely, the tumor can be shelled out, more often it is found to surround the great vessels of the abdomen. The operative mortality is from 30 to 40 per cent, of twenty surgically treated patients in New York City, whose cases I studied, nineteen died.

SUMMARY

For successful treatment of malignant tumors of the urogenital tract in children, early diagnosis is imperative, urography, aspiration biopsy in the case of renal growths and the modified Aschheim-Zondek test in the case of testicular tumors are important. Radiation therapy merits first place in the immediate treatment of these tumors, especially in the young, and only by its intensive employment—preoperatively and postoperatively by the divided daily dose method—together with judicious surgical intervention, can one hope to reduce their appalling mortality.

140 East Fifty-Fourth Street

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS WHARTON, GRAY AND GUILD,
DR HEPLER AND DR CAMPBELL

DR VINCENT VERMOOTEN, Johannesburg, South Africa. "Achalasia" of the ureter is a term which has recently been used in Britain to describe the dilated ureter in children, presupposing that it is a condition similar to Hirschsprung's disease. The word is derived from the Greek *α*, negative, and *χαλασις*, relaxation, and should therefore be used to indicate the failure to relax on the part of a bodily opening such as a sphincter or the esophagus. Dr Hepler uses the term to indicate the incoordination between peristalsis on the one hand and the relaxation and expulsive activity at the ureterovesical junction on the other. Also he bases his thesis on the existence of a sphincter at the ureterovesical junction, a fact which I am inclined to doubt. That the condition may actually exist is probably correct, but I feel that the term 'achalasia' is an unfortunate choice, and so too is his advocacy of sympathectomy for the relief of the condition. He refers particularly to Berkman's report in which a case of the exactly opposite type of segmental neuromuscular imbalance (increased tonicity or spastic contraction of the ureterovesical junction) was relieved by sympathectomy. It is difficult for me to understand how the same operation can relieve two conditions of a distinctly opposite nature. As for the sphincter at the ureterovesical junction, Dr Hepler states that according to the work of Hinman and Wesson the lower and intramural ureter and vesical trigon may be considered as an anatomic and physio-

21a. This child died of his tumor shortly after this paper was submitted for publication.

logic unit. Assuming this to be correct, one would therefore be surprised if the ureteral orifice remained patently open or closed and did not retract or dilate as the normal peristaltic wave passes down a normal ureter. If one can pass one or two very small catheters through a ureteral orifice into a ureter the lumen of which is ten or more times greater, it does not necessarily indicate that there is no actual mechanical obstruction at the ureterovesical junction. If there should be a ureterovesical junction the diameter of which was, say, 0.5 cm and an associated ureter the diameter of which was, say, 3 cm, that junction would be, relatively speaking, an obstruction to the free flow of urine from the ureter, at least far more so than if the lumen of the ureter was also 0.5 cm in diameter. This would be all the more true if the ureter itself was somewhat atonic. Can one therefore find some explanation other than a segmental neuromuscular imbalance for these dilated ureters with no apparent obstruction at the ureterovesical junction? I feel that a large percentage of the so called achalasias of the ureter can be explained if one is willing to accept Chwalla's work on the embryology of the ureter, which has apparently been overlooked by Dr Hepler and by other urologists who have written on this subject.

DR. HENRY F. HELMHOLZ, Rochester, Minn. I was particularly interested in the paper of Drs Wharton, Gray and Guild because it represents the sort of thing that pediatricians have been trying to call attention to, namely, the importance of a complete urologic examination if urinary infections cannot be cleared up. I do not believe that we were told in how many of these cases the infection persisted, and I, for one, and the urologists have been constantly calling to the attention of the medical men that a patient should not be discharged until one knows that the infection is actually cured. By cured I do not mean the absence of pus in the urine but the absence of bacteria determined by culture after discontinuation of the treatment. I think that this is the all important point in the treatment of pyelitis. Only in this way can one be sure that there will not be a series of cases that have gone along the way this series has, so that after a period of anywhere from five to fifteen or twenty years these infections still persist. I feel sure that those cases in which the urinary tracts were normal could have been cleared up with intensive therapy even back in the days when we were using only methenamine. Certainly at the present time with the new drugs that we have at our disposal that should be readily accomplished. When infections do not clear up rapidly, a urologic examination is essential and it ought not to be necessary to tell this to a group of urologists—they have been telling us of the necessity of this procedure. I, for one, have been preaching to my pediatric confreres the importance of a cure controlled by cultures in all cases and the necessity of a complete urologic examination when this is impossible.

DR. ALBERT E. GOLDSTEIN, Baltimore. The term "pyelitis" which Wharton, Gray and Guild use might be misleading, although it was stated that the term was employed in a general sense. If the cases are those of pyelitis with frequent attacks, the kidneys surely cannot be considered normal as the authors made mention of. This is borne out by postmortem specimens which show in these cases that there are lesions in the kidney cortex which on microscopic study show definite abnormality in the form of round cell infiltration. I can't conceive of a case of pyelitis in which there is an infection in the pelvis without an infection in the parenchyma of the kidney. That certainly can be misleading to most of us and we should be careful about it. I think the burden of proof is on the examiner when he claims that he is dealing with a case of pyelitis without having the patient examined cystoscopically and the urine obtained from the kidneys. I do not see how it is possible to state that there is a kidney infection from symptomatology alone or from the obtaining of a specimen of urine and finding pus. That doesn't seem quite reasonable, yet in all probability the symptomatology points to the kidney. The early examinations which they make note of here, while they may not have been possible certainly should not be considered pyelonephritis until urine is obtained from each kidney and pus and organisms have been demonstrated. This is important because I believe that otherwise we shall be classifying

all these cases as pyelonephritis. A better term, as Dr Helmholtz designated, would be infection of the urinary tract. One should then determine whether one is dealing with just a cystitis or with a urethritis. Nevertheless, the work done by the authors furnishes a tremendous amount of food for thought. All these cases should have careful urologic and systematic and routine examinations when pus is found in the urine.

DR. WILLIAM E. STEVENS, San Francisco. In the presence of fever of uncertain origin in infants, pyelitis should always be suspected. Pyelitis during infancy is a self-limited disease in 50 per cent of cases. Some abnormality of the urinary tract will be found in about one third of the remainder. Pyelitis may persist indefinitely, however, with few, if any, symptoms. Other cases progress more rapidly and, if untreated, result in destruction of the kidney. I believe that pyelitis occurring during pregnancy is occasionally an exacerbation of low grade infection that has persisted since infancy. The same urologic procedures that are useful in adults, such as cystoscopy, ureteral catheterization, functional kidney tests and pyelography, should be more universally employed in the examination of the urinary tract in these patients.

DR. WILLIAM F. BRAASCH, Rochester, Minn. The paper of Dr Wharton and his co-workers contains many data which should prove to be of great clinical value. I was especially interested in those data concerning the relation of pyelonephritis of children to chronic renal infection of the adult. It has been a moot point whether adult renal infection continued from renal infection of children or whether its origin was recent and independent. I have always believed that renal infection of children had little or no bearing on adult renal infection, and that infection which continued from childhood was due to some abnormality such as Drs Wharton, Gray and Guild have mentioned. It is of interest that they so frequently find renal infection persisting from childhood to adult years without the presence of any abnormality. Although the comparative incidence of infection which continues from childhood probably is small, it is evident that it can occur. Dr Wharton and his co-authors called attention to the fact that children with repeatedly recurring attacks of pyelonephritis were particularly likely to have the infection continue into later years. It is my impression that these recurring attacks represent acute exacerbations of continued chronic pyelonephritis rather than separate episodes. It would seem probable that recent methods of chemotherapy will eliminate many infections of children and will reduce to some extent the incidence of pyelonephritis of adults. I also want to refer briefly to the interesting observations made by Dr Hepler. About twenty-two years ago I first read a paper on atonic or inflammatory dilatation of the renal pelvis and ureter before this section in Atlantic City. I described the pathology and urographic diagnosis of this condition and showed how atonic or adynamic pyelo-ureterectasis differed from the dynamic form. It would seem that an embryonic etiology is present in but few cases of adynamic ureterectasis. It is usually not difficult to distinguish between the microscopic pathologic changes of the two conditions. Adynamic ureterectasis usually results from infectious changes, leaving a thickened ureteral wall with much cicatricial tissue. With dynamic ureterectasis, on the other hand, the wall is thinned and contains but few cicatricial cells. It should be remembered that both dynamic and adynamic ureterectasis may be present and it may then be very difficult to identify the predominant factor. Trautner's contributions to the physiologic distinction between the two conditions are particularly significant. It is difficult to explain how ureterectasis follows inflammation. Possibly it is caused by disturbance of innervation of periureteral origin; however, ureteroscopy will demonstrate but little reduction in ureteral peristalsis.

DR. ALEXANDER B. HEPLER, Seattle. Considering the uncertainties which surround this subject, the criticisms have been very generous. This is still a controversial subject. This condition has not been established as a definite entity. I simply wanted to add some clinical observations on these nonobstructive dilatations in the hope that by the discussion stimulating interest we could come to a nearer solution of the mechanism that is behind it.

FRACTURE OF THE SKULL INVOLVING
THE PARANASAL SINUSES
AND MASTOIDS

C C COLEMAN, M D

RICHMOND, VA

Fracture of the skull involving the paranasal sinuses and mastoids is important mainly because it exposes the brain to infection. Less serious effects are paralysis of cranial nerves and facial deformity from displacement or loss of bone fragments.

Fractures of the skull, whether of the vault or base or, as they usually are, of the two in combination, frequently produce serious damage to the brain, and the brain injury should receive primary consideration. Fracture of a paranasal sinus is often only a minor effect of an injury which damages important regions of the brain at the base of the skull and severely macerates the cerebral cortex by the indriven fragments of an associated compound fracture of the vault. Consideration of the sinus fracture in serious cases of head trauma must at times be postponed or even entirely abandoned in favor of a management which gives the patient the best chance to withstand the primary effects of his injury.

The two main objectives of surgical treatment of head trauma are the prevention of infection and the removal of intracranial hematomas. Open wounds of the vault of the skull, while often inadequately treated, should present few problems of management to surgeons familiar with such injuries. The situation created by compound fractures of the base of the skull, because of their extent and frequent inaccessibility and their common association with severe fractures of the vault, is often a most complex one, totally unfavorable to effective surgery.

The limitations of the x-ray examination in the demonstration of fracture lines at the base of the skull are well known, and the diagnosis must generally depend on such effects of the fracture as bleeding from the cranial orifices, cerebrospinal fluid leaks, suggestive ecchymoses and palsy of the cranial nerves.

The situation is better with respect to the sinuses accessible to surgical exploration, such as the frontal and the anterior ethmoid, but even with fractures of these sinuses one cannot often be sure that operation is required to close a dural laceration for the prevention of meningitis. If operation is done, other dural lacerations in the remote ramifications of the fracture line, even more important than the sutured laceration, may be entirely unsuspected.

The uncertainties as to the location and extent of a fracture of the base involving the sinuses, and the difficulty in the majority of cases of determining the presence of dural lacerations, tend naturally to the promotion of conservatism in the management of these injuries. Unless there is good reason to believe that an accessible dural laceration exists, with communication between the bony sinuses and meningeal spaces, operation is not advisable.

The dangers of fracture of the paranasal sinuses depend almost entirely on the laceration of its dural covering, and the only positive sign of such laceration is a cerebrospinal fluid leak or pneumocephalus. Cere-

brospinal fluid leaks may result from fracture of any of the cranial sinuses. When the fluid is escaping from the nose or mouth the dural fistula may be in either the anterior or the middle fossa. A dural tear in the middle or posterior fossa may permit the discharge of cerebrospinal fluid from the ear. Fluid discharged from the nose or mouth escapes more often through the cribriform plate than from either the frontal or the sphenoid sinus, although the sphenoid is believed by Rawlings to be involved in from 40 to 50 per cent of all basal fractures.

Local applications to the nasal passages, packing and intranasal douches used in an effort to prevent infection in cases of fracture of the base are not only futile but harmful. If the dural laceration can be closed, meningitis may be prevented, otherwise the development of meningitis will depend almost entirely on whether the fractured sinus through which the fluid is escaping is infected.

Compound, depressed fractures of the frontal region frequently involve the frontal sinus, with extension of the fracture line into the floor of the anterior fossa and through the ethmoids. Patients with fractures of this type, notwithstanding the severe laceration of the frontal lobe, are often free from shock, and early operation for the prevention of infection should be done. Fragmentation of the walls of the sinus is not uncommon in this type of injury, and the dura may be extensively lacerated. In the operation for such a wound it is of the greatest importance that a secure closure of the dura and scalp be made to prevent infection or herniation of the brain through the orbit. The debridement of the wound should include removal of fragments of bone from the wall of the sinus and generally the removal of its mucous lining. Drainage of the sinus may be used, but the drainage material should not be placed in contact with the sutured dural laceration. The prognosis of these severe injuries is excellent, provided all contaminated tissue, including pulped brain, is removed and the dura securely closed.

Depressed fracture of the outer wall of the sinus is not infrequent. This fracture, while often compound both externally and internally, is sometimes unique in being confined to the sinus and often requires no treatment other than disinfection, excision and suture of the cutaneous laceration. If the outer wall is deeply depressed, operation is required to elevate the bone and to permit a thorough inspection of the sinus. Depression of the supra-orbital region, if of concern to the patient, may be leveled later with rib cartilage.

The frontal sinus may be involved in linear fractures which radiate from the vault, and in these cases there is much difference of opinion as to treatment. The majority of such fractures pass through the walls of the frontal sinus to the floor of the anterior fossa and may or may not lacerate the dura covering its inner wall. I know of no way to determine whether the dura is lacerated except by inspection. The presence of bloody spinal fluid means only that there has been subarachnoid hemorrhage, but the source of subarachnoid bleeding as determined by lumbar puncture is nearly always a matter of conjecture in cases of head injuries. Even if the dura is lacerated by a linear fracture of the inner sinus wall, and this is infrequent and generally a matter of considerable doubt before operation, meningitis seems unlikely unless the sinus is infected or a hematoma of the sinus develops. I have treated such cases conservatively if there was no evidence of infection in the sinus.

or indications definitely pointing to a hematoma or a leak through the sinus with or without adjacent pneumocephalus. A conservative attitude toward this type of fracture seems to be justified by my own experience.

In a series of 940 cases of head trauma observed at the Neurosurgical Service, Hospital Division, Medical College of Virginia, in 1935-1936, there were 216 fractures of the skull, with eighty-seven fractures of the base. Of the eighty-seven basal fractures, fifteen involved the frontal sinuses, six of these were associated with severe compound, depressed fracture of the frontal vault and operation was promptly done for disinfection, debridement and closure of the dura. One patient with a slightly depressed compound fracture of the outer wall of the frontal sinus was treated by debridement and suture of the laceration overlying the fracture. Prompt recovery followed in this group. There were seven patients with linear fracture of the frontal sinus, and all recovered promptly without operation. One patient with a linear fracture of the frontal sinus died of meningitis eleven days after admission. In addition to the fracture of the right frontal sinus, autopsy disclosed comminution of the ethmoids, with extension of the fracture through the petrous portion of the temporal bone on the right side. Extensive laceration of the brain was present, and fractures of both arms, thigh, ribs and a chest injury indicated the body-wide violence of the trauma. Because of the patient's serious condition no attempt at x-ray diagnosis was made. This case illustrates well the difficult situation not infrequently found in dealing with fracture of the skull involving the paranasal sinuses.

I have exposed the anterior ethmoids a few times to close a laceration in the dura when there was a persistent cerebrospinal fluid leak. In one case this was done for the cure of pneumocephalus of the left frontal lobe. It may be done through a small frontal flap, with elevation of the dura from the floor of the fossa, access thus being given both to the inner wall of the frontal sinus and to the ethmoid on the side of the operation. It is only in the exceptional case that operation to close a cerebrospinal fluid leak presumably from a fracture of the ethmoid is advisable, but the operation may be entirely successful and should be undertaken if the leak persists for three or more days after injury, provided the patient's condition permits.

The dangers of coughing, sneezing and straining when there is a basal fracture have been frequently emphasized. Vomiting and respiratory difficulties of the unconscious patient also increase the risk of intracranial infection in the early stages of the injury, and meningitis often develops in the first few days.

Pneumocephalus is a rare complication of head trauma. Although we have employed x-ray examination almost as a matter of routine in the study of head injuries, the condition has been discovered in only four cases. In two of these cases the air was in the subarachnoid space, and in one patient there was a small amount in a lateral ventricle. Both patients had free bleeding from the nostrils, and on the day of admission subarachnoid air was demonstrated by x-ray examination. One patient died on the third day, of pneumococcal meningitis. The other made a prompt recovery without operation. In both cases the air was believed to have entered through a fracture of the cribriform plate, as is usually the case when air has a subarachnoid distribution. Two other patients had large pockets of

air in the frontal lobe, one on the left and the other on the right. Pneumocephalus had been recognized by x-ray examination in both these patients before admission. Neither had a cerebrospinal fluid leak while under observation, but one had a history of rhinorrhea for some days after a severe compound, depressed left frontal fracture about six weeks before. This fracture had involved the left frontal sinus and ethmoid, and among other things had paralyzed the left third nerve, and there seemed to be some involvement of the right third nerve. At no time was there a sudden escape of fluid from the nose on sneezing. There was no indication of increased pressure. Operation was undertaken to elevate a depressed fracture of the vault and to eradicate the large pocket of air in the frontal lobe with a stalk leading to the ethmoid region. The anterior ethmoid region was exposed extradurally through the bony defect made by removal of the depressed bone fragments, and the air cyst was incised. Its communication with the ethmoid sinus was plainly shown. A dural tube, caught in the crevice of the fracture through which the air entered the frontal lobe, was released and obliterated by suture. There was no connection of the pneumocephalus with the frontal sinus. Prompt recovery followed the operation. In a second case a large air pocket was present in the right frontal lobe. Intracranial pressure was normal. Through a frontal burr opening the air was displaced by Ringer's solution, which was allowed to flow into the pocket by gravity while a second needle provided for the escape of air from the pocket. Roentgenograms seven months later showed no reaccumulation of air. There was no fracture of the frontal sinus demonstrable in this case and no history of a cerebrospinal fluid leak.

In cases of acute head injury, the discovery of intracranial air should lead to repeated x-ray examinations to determine whether the amount of air is increasing or diminishing. If it is increasing or is stationary for three or four days and cerebrospinal fluid is escaping, surgical intervention for closure of the dural laceration is indicated. In cases of large air pockets under tension and associated with a leak of fluid, operation is strongly indicated to close the fistula. If a leak is not present even intermittently, and the intracranial tension is not raised, the air may be released by puncture of the air cyst and the cavity filled with Ringer's solution.

Fractures of the mastoid and petrous portion of the temporal bone are recognized usually by such indirect evidence as bleeding from the ear in the absence of injury to the external canal, escape of cerebrospinal fluid, Battle's sign and involvement of the seventh and eighth nerves.

Hemorrhage from the ear is rarely profuse, and no treatment is required except cleansing of the external canal and auricle with alcohol and covering of the ear with a sterile dressing. There is not infrequently a collection of blood in the middle ear, and this may become infected, giving rise to otitis media and mastoiditis. In the presence of a compound fracture through the petrous portion of the temporal bone, the development of otitis media or mastoiditis places the patient in great danger from intracranial infection. To lessen the danger from retained hemorrhage of the middle ear when the drum membrane is unruptured early paracentesis should be done, and this is urgently required if the tympanic membrane shows evidence of increased intra-aural tension. Early surgical treatment of mastoiditis secondary to fracture is of the greatest importance. It is obvious that the welfare of the patient

with fracture of the mastoid or petrous portion of the temporal bone is best protected when there is close cooperation between the otologist and the neurologic surgeon. These injuries frequently come within the domain of both specialists, and treatment without appreciation of this fact is not conducive to the best results.

In forty-nine of the eighty-seven cases of fracture of the base of the skull there was free bleeding from one or both ears. Four patients died as a result of intracranial infection, giving a mortality rate of 8.16 per cent.

Compound, depressed fracture of the mastoid with laceration of the lateral sinus in one case (not in this series) caused a hemorrhage from the ear which nearly exsanguinated the patient. Arrest of the hemorrhage was accomplished by exposure of the lateral sinus and occlusion of the tear with a large muscle graft. In two cases, disabling Meniere's syndrome followed fracture of the petrous portion of the temporal bone. The two patients had deafness, a leak of cerebrospinal fluid after injury and temporary facial paralysis. Intracranial section of the auditory nerve completely relieved one patient, while the other did not improve but refused operation.

The main purpose of this discussion is to emphasize the dangers arising from infection in fracture of the base of the skull. Only a brief reference may be made to injuries of the cranial nerve which may result from these fractures. The first eight cranial nerves are liable to injury from fractures which traverse the paranasal sinuses or mastoid. Blindness of one eye, extra-ocular palsy and anosmia are not rare with fractures of the anterior fossa. Unilateral blindness and deafness are usually permanent. Oculomotor involvement with dilatation of the pupil, due to fracture, comes on immediately, while later dilatation of one pupil indicates a homolateral clot. Facial paralysis following fracture of the skull is rarely permanent. It usually appears a few days after injury. Inflammation is probably the chief cause of this paralysis. Permanent paralysis of the nerve requires anastomosis with another healthy motor cranial nerve.

ABSTRACT OF DISCUSSION

DR FRANCIS C GRANT, Philadelphia. There is no question about the method of handling a cerebrospinal fluid leak from the ear. I leave all those cases alone. The external canal is kept sterile. The patient is turned with that ear down to encourage drainage. No lumbar punctures are done, and nothing is done to interfere with the escape of the fluid. My experience has been that the fluid leak will disappear spontaneously at the end of four or five days. I looked up statistics on the escape of cerebrospinal fluid from the ear in the last two years. There have been sixty-three cases, with one patient dying from a meningitis. The others recovered. My impression is that a cerebrospinal fluid leak from the ear properly treated, gives the patient a good prognosis because decompression had been done at the time of his injury. The escape of cerebrospinal fluid from the nose is an entirely different problem. I agree with Dr Coleman that when one knows exactly the situation of the leak, as is not uncommonly the case in a badly compounded fracture with a tear in the dura, every effort should be made to close that defect leaving a water tight dura. The difficult cases to handle are those of a rhinorrhea with no definite evidence as to whether the fluid is coming through the cribriform plate or one of the sinuses. I do not believe that operation should be done unless one is absolutely certain of the point at which the dura has been torn. My experience in the last six cases of compound frontal fractures with leakage of cerebrospinal fluid from the nose has been four recoveries following operation. I have had five

patients without a demonstrable fracture line and two of those have died from meningitis without operation. I did not feel in any of these five cases that operative intervention was justified, because I did not know the point at which the dura had been torn. A transfrontal craniotomy is a major operative procedure requiring special instruments and technic. Furthermore, unfortunately, the dura in the frontal area is thin and difficult to suture. If thin dura is encountered that tears when one attempts to suture it, the proper procedure is to place a pad of muscle over the area and sew the dura together over the muscle. Then carry a drain through the operative field, attempting to sidetrack the cerebrospinal fluid leak from the potentially infected sinus out through the presumably sterile operative field.

DR WELLS P EAGLETON, Newark, N J. Any fracture which passes through the sinuses is a dangerous fracture if the dura is torn, because a fracture which extends from a frontal sinus through the dura and into the brain has a direct communication with the outer world. It is in reality a compound fracture. A fracture through a nasal sinus with a tear in the dura may not only cause meningitis promptly but a 'late meningitis', because, in its effort to repair, the mucous membrane of the sinus grows rapidly into the defect and may continue its growth wherever there is damaged cerebral tissue, causing a large cyst connected with the frontal sinus. Later, if the mucous membrane of the nose becomes infected by a cold, bacteria may pass from the nose through the crack and the dura into the arachnoid by direct continuity of tissue infection. In the *Journal of Laryngology and Otology* (November 1929) I described three such cases. All terminated in a late meningitis. As a result of these experiences, I now put a layer of skin or fascia lata tucking it in and thus short-circuit the nose from the pia-arachnoid by walling off the sinus, so as to prevent later infections. If the tear is small, I take a piece of mucous membrane from the mouth and place it over the defect with the freshly cut surface applied against the dura. Fractures through the temporal region cause meningitis in only 8 per cent of the cases. I have a definite rule about such cases. I keep the patients in bed and watch them carefully. If the temperature rises, associated with headache, or if there is a rise in temperature which cannot be accounted for and the cell count in the lumbar fluid is increased, I operate and follow the fracture wherever it leads. I have cured one case of meningitis in which the fracture went directly across through both petrous apices.

DR CLAUDE C COLEMAN, Richmond, Va. Dr Grant has referred to the posture of the patient with leakage of cerebrospinal fluid from the ear. It has been rather difficult for me to determine just what is the best position for these patients, that is, whether the leaking ear should be down or up. If the escape of cerebrospinal fluid is encouraged by placing the leaking ear down, fluctuation in intracranial pressure by loss of fluid might tend to promote infection by aspiration from the ear into the meningeal spaces. I have treated these patients in both ways but have preferred to place the patient in bed with the leaking ear uppermost. Dr Grant has emphasized the difficulty in determining when a dural laceration should be closed. If one knows that the laceration is accessible, certainly it would be good surgery to attempt closure, provided the patient's condition will permit such a procedure. A fracture may start in the frontal region, extend through the cribriform plate and involve the petrous portion of the temporal bone. In such a fracture it would be difficult if not impossible to determine the location of the dural laceration responsible for the leak. One is sometimes able to be reasonably sure of the location of the dural laceration responsible for the leak, and if such laceration is accessible it should be sutured or repaired with fascia. The presence of blood in the cerebrospinal fluid associated with a fracture of the posterior wall of the frontal sinus, is considered by Dr Eagleton to be an indication of a laceration of the dura adjacent to the fracture. Subarachnoid bleeding is frequently caused by head injury and even when the patient has a fracture of the frontal sinus the subarachnoid hemorrhage as determined by spinal puncture might easily come from some part of the subarachnoid space remote from the fracture. Mastoiditis and aural infections following fracture of the petrous portion of the temporal bone are problems

for the otologist. Such cases in my clinic are treated by the otologist. The importance of early operation on mastoid infection secondary to fracture of the petrous portion of the temporal bone should be emphasized. It would seem that these cases would be especially liable to intracranial infection if not promptly treated.

BREECH DELIVERY

A COMPARATIVE STUDY OF LOCAL AND GENERAL ANESTHESIA

MAGNUS P. URNES, M.D.
AND
HARRIS J. TIMERMAN, M.D.
CHICAGO

Breech presentation is always of interest because of the difficulties and complications so often encountered. The problem of a suitable anesthetic is a pertinent one. It is the purpose of this paper to present the results of a large series of breech deliveries in the home and the technic employed, with special reference to the use of local anesthesia. During the four year period July 1, 1932, to June 30, 1936, 11,772 patients were delivered at the Chicago Maternity Center. Three hundred and forty-six breech presentations occurred in 336 cases, an incidence of 2.8 per cent. Seventy patients were primiparas and 266 multiparas.

TABLE 1—Eighty-Six Operative Deliveries 24.9 Per Cent of 336 Cases

Operations	No.	Para sacral	Puden dal	Ether	Mixed	None
Breech extraction	16	7	2	4	1	2

Breech extraction with cranialotomy	3	2	0	1	0	0
Cesarean section	2	0	0	1	0	0
Totals	86	23	30	21	9	2

The Chicago Maternity Center is a large outpatient obstetric service. All patients are delivered in the home except those with antepartum bleeding or severe toxemia and those for whom cesarean section is advised. Only two patients were hospitalized primarily because of breech presentation. Both had markedly contracted pelvis and both were delivered by cesarean section. An intern, a nurse and one or more students conduct the labor and delivery in the normal cases. The resident sees all patients when breech presentation is diagnosed, and either he or one of the attending staff conducts the delivery. At times, however, the intern must conduct the delivery alone, either because of his failure to make the diagnosis or because of a very rapid labor. Several babies probably were lost that might have been saved had the resident, with adequate equipment, been present. When the time for delivery is imminent the patient is placed on a table and everything prepared for immediate intervention should that become necessary. Her legs are supported by students or members of the family. The sterile instruments in pans and basins of solutions are placed on a board supported between two chairs on the operator's right. The intern acts as the assistant and another intern as the anesthetist if ether is to be used. It is our policy to allow the patients to deliver spontaneously unless a

definite indication arises for intervention, with the exception that an episiotomy and a prophylactic application of forceps to the aftercoming head are done on most primiparas. In our opinion an episiotomy is indicated for primiparas and forceps to the aftercoming head saves much delay and decreases the incidence of birth injuries from the strong traction on the neck so often necessary. The De Lee modification of the Simpson forceps is used. In these cases and in cases of multiparas in which assistance seems likely, a pudendal block anesthesia is induced as soon as the breech is distending the perineum. The breech is allowed to be born spontaneously, and manual aid is given to the shoulders, if necessary. The head is brought into the pelvis by combined pressure from above with the outside hand and traction below with a finger in the baby's mouth and is then delivered by forceps.

Local anesthesia, although not new in obstetrics, apparently has been used little for breech delivery. King¹ in 1916 and Torlund² in 1930 described a method of perineal block and recommended its use for normal deliveries and repairs. The original technic for pudendal block was described by Laven. Our method differs somewhat from the others but accomplishes the same result. We have found it particularly adaptable for breech deliveries. The patient is awake and able to cooperate to deliver her baby spontaneously. The uterine contractions are not affected. The relaxation of the pelvic floor and perineum obtained is comparable only to that with surgical ether anesthesia, and the excruciating pain attendant on the distention of the pelvic floor and perineum is completely obliterated. Episiotomy and forceps to the aftercoming head (except high forceps) can be performed easily with little discomfort to the patient. The duration of the anesthesia is about one hour and a half.

TECHNIC OF PUDENDAL BLOCK

With the patient in an exaggerated lithotomy position, intradermal wheals are made bilaterally half way between the rectum and the tuberosity of the ischium. One per cent procaine hydrochloride with 2 minims (0.12 cc.) of epinephrine (1:1,000) per ounce (30 cc.) is used. The index finger of the left hand inserted into the rectum palpates the left ischial spine. A 10 cm. needle is passed horizontally through the cutaneous wheal directly to the spine and then allowed to slip just under and beyond it. Because of the direction of the needle and the guiding finger in the rectum there is no danger of piercing the rectum. From 10 to 15 cc. of solution is deposited at this point, blocking the internal pudic nerve as it passes dorsal to the spine of the ischium just before entering Alcock's canal. The needle is then withdrawn until it lies just beneath the skin. The direction is changed laterally toward the tuberosity of the ischium, and the needle is inserted until the point strikes the bone. Five cc. is injected while the needle is gradually being withdrawn. This anesthetizes the large perineal branch of the posterior cutaneous femoris. Again the needle is withdrawn until it lies just under the skin, and its direction is changed vertically upward. While it is advancing, 5 cc. is deposited in the subcutaneous tissue of the labium majus, blocking off the perineal fibers of the ilio-inguinal nerve. The procedure is repeated on the opposite side, the operator using the same finger in the rectum or changing to the index finger of the right hand. The vaginal mucosa and the skin of the perineal area as high as the clitoris

become anesthetized within five minutes. Relaxation of the levator ani and the perineal muscles is usually complete.

An analysis of this series of 346 deliveries reveals that eighty-six, or 24.9 per cent, were terminated by operative intervention. Two hundred and sixty patients delivered spontaneously. Table 1 lists the operations and the anesthetic agent under which they were performed. Pudendal block was used successfully for episiotomy and forceps to the aftercoming head twenty-eight times. In three instances it was necessary to supplement the local anesthesia with a small amount of ether.

Should an indication arise necessitating breech extraction, parasacral block anesthesia is induced. Five extractions were done with the patient under pudendal block with one fetal death, but this method is not recommended because little or no relaxation of the uterus is obtained. During 1932 and part of 1933, before parasacral anesthesia was used to any extent, drop ether was the anesthetic of choice for this type of delivery.

The technic of parasacral block has been described in detail by Tucker and Benaron.³ The anterior sacral nerves are blocked as they leave the anterior sacral foramina. The uterine contractions are obliterated, and sufficient relaxation of the uterus is obtained for the extraction to be performed. As with pudendal block, the pelvic floor and perineum are relaxed and complete cutaneous anesthesia results in practically all cases. Twenty breech extractions were performed by this method, with two fetal deaths in eighteen viable cases, a fetal mortality of 11 per cent.

Contraindications to the use of local anesthesia for extractions, or even for the simpler operations, are threatened rupture of the uterus, severe fetal asphyxia and inflammatory lesions of the perineum. In the cases presenting one of these objections and in the early cases previously mentioned, ether was used. In six cases the parasacral block was supplemented by ether anesthesia because in the operator's judgment not enough relaxa-

MATERNAL COMPLICATIONS

The more common maternal complications of delivery encountered are listed in table 2. Postpartum hemorrhage was the most frequent and the most serious. It occurred twenty-eight times in the entire series of 336 patients, an incidence of 8.4 per cent. The average loss of blood was 830 cc. in the cases of hemorrhage. Seventeen of the twenty-eight deliveries had terminated spontaneously. Eight cases of hemorrhage occurred after breech extraction, of which four were in the

TABLE 3—Fetal Deaths (Corrected), Twenty-Three, 66 per Cent

parasacral series and four in the ether series. In the forty spontaneous deliveries with forceps to the aftercoming head there was one hemorrhage when pudendal block was used and two when ether was the anesthetic. There were, however, twenty-five cases of pudendal block and only twelve of ether anesthesia in this series.

Manual removal of the placenta was performed thirteen times, an incidence of 3.8 per cent. Six of these cases were in the spontaneous group and seven in the operative group. Four of the extractions under ether required this intervention while only two of those under parasacral anesthesia needed it. The remaining case occurred in a forceps delivery with ether anesthesia. There was one ruptured uterus, following a difficult extraction with high forceps to the aftercoming head, with the patient under ether anesthesia. The patient, a multipara, had been in labor many hours under the care of a midwife, who had made several unsuccessful attempts at extraction. When the operative personnel of the Maternity Center was called the mother was exhausted and the fetus in poor condition. When a massive hemorrhage immediately followed the delivery, a ruptured lower uterine segment was discovered on intra-uterine exploration. Manual removal of the placenta was followed by insertion of a uterine pack and the patient was hospitalized. A supracervical hysterectomy was performed. Both mother and baby made an uneventful recovery.

MATERNAL MORTALITY AND MORBIDITY

There was one maternal death in this series, a mortality of 0.3 per cent. A brief summary of this case is given.

A Mexican septigravida, aged 38, had antepartum care at the Chicago Maternity Center and on May 8, 1934, was delivered spontaneously without anesthesia of a 1,400 Gm. stillborn fetus. At the time of delivery her temperature was 100.2 F. and there were pulmonary symptoms. She was hospitalized on her second postpartum day with a diagnosis of pulmonary tuberculosis. Death followed on the twelfth postpartum day. Autopsy revealed the cause of death to beiliary tuberculosis.

It is difficult to evaluate with any degree of accuracy the morbidity in a home series such as this because the

TABLE 2—Complications Encountered at Delivery

Complication	No.	Spontaneous		Spontaneous with Forceps		Extraction	
		No Anesthesia	Pudendal	Block	Ether	Parasacral	Ether
		260	25	12	20	17

Ruptured uterus	1	0	0	0	0	1	
Cervical laceration	2	1	1	0	0	0	

tion of the uterus was obtained for him to proceed with safety. These are the cases classified as mixed in table 1. In the seventeen cases of extraction performed with ether or mixed ether and local anesthesia there were four fetal deaths, a fetal mortality of 25 per cent. The total mortality for the forty-four breech extractions was 17 per cent. This figure compares favorably with recent reports of large series of breech extractions reported by Gordon and Garlick⁴ from Brooklyn and by Cannel and Dodek⁵ from Cleveland.

³ Tucker, Beatrice E. and Benaron, Harry B. W. Am. J. Obst. & Gynec. 27: 850-863 (June) 1934.
⁴ Gordon, Charles A., Garlick, Ralph and Oginsz, Philip. Am. J. Obst. & Gynec. 28: 140-150 (July) 1934.
⁵ Cannel, Douglas E. and Dodek, Samuel M. Am. J. Obst. & Gynec. 27: 517-528 (April) 1934.

temperature is taken only once a day. We felt, therefore, that morbidity statistics for this series would be of little value, and so they were omitted.

FETAL MORTALITY

Of the 346 babies born, sixty-five were stillborn or died during the first two weeks of life, a gross mortality of 19 per cent. Of this number twelve were nonviable (under 1,500 Gm.), eleven monsters and nineteen macerated. Deducting these cases, twenty-three babies were lost, giving a corrected fetal mortality of 6.6 per cent.

Table 3 lists these fetal deaths under the various forms of delivery and anesthesia and their cause as determined at the time of delivery or at autopsy. Dystocia with the aftercoming head was the most frequent complication and occurred seven times, five of the seven in spontaneous deliveries. In each instance the labor was rapid and the intern had to conduct the delivery without assistance from the resident staff. Shoulder dystocia was the cause of stillbirth in two cases, one in a spontaneous delivery and the other in a breech extraction with parasacral anesthesia. In the latter case the fetus weighed 10¾ pounds (4,876 Gm.). Autopsy revealed cerebral injury as the cause of death in three fetuses in which no dystocia was recorded. Prolapsed cord accounted for two deaths. Two neonatal deaths resulted from pneumonia. There were seven deaths of undetermined origin.

CONCLUSIONS

1 The fetal mortality of this series of breech deliveries in homes compares favorably with that in reports of recent hospital series.

2 Parasacral anesthesia for breech extractions in our opinion is preferable to ether anesthesia, since in this series the fetal mortality was slightly lower and the incidence of maternal complications definitely lower when it was used. It possesses the added advantage that its use does not require the presence of a skilled anesthetist in addition to the operator, and it may be used in cases of toxemia or pulmonary complications.

3 Pudendal block anesthesia is particularly adapted to spontaneous delivery with episiotomy and forceps to the aftercoming head. It produces no relaxation of the uterus, so that the serious complications of postpartum hemorrhage and manual removal of the placenta will not occur as frequently as with the use of ether.

4753 Broadway

ABSTRACT OF DISCUSSION

DR. JOSEPH B. DE LEE, Chicago: The importance of topical or local or regional anesthesia in breech cases is being recognized more and more. In a paper on the subject by C. McIntosh Marshall (*J. Obst. & Gynec. Brit. Emp.*) the importance of local anesthesia was stressed and proved. It is proved again by Urnes and Timmerman. Local anesthesia is very simple and can be used by any doctor with ordinary ability. The apparatus can be sterilized in the office, and the materials for injection can be obtained in ampules so that they do not have to be prepared at the place of the operation. I might also call attention to the superiority of forceps to the aftercoming head, to replace the brutal and violent measures that heretofore have been adopted for these cases. The Mauriceau-Smellie-Veit and the Martin-Wiegand-Celsus procedures should be abolished from the treatment of breech presentation. If the head does not enter the pelvis with moderate pressure from above aided by moderate traction on the jaw from below, which traction, however, is not used to pull the baby out but is used to adjust the baby's head to the best diameter and the circumference of the pelvis, the forceps should be applied to the aftercoming head. It is not necessary to have a special forceps like Piper's.

The ordinary Simpson forceps will do just as well. I would like to make one correction in respect to the use of the term the prophylactic forceps to the aftercoming head. One tries to prevent damage to the mother and baby by the forceps operation, and therefore all forceps operations are prophylactic. However, the so-called prophylactic forceps operation is intended to be used in cases in which the head has passed the cervix and has come down to rest on the perineum, has completely rotated, and is retained by the pelvic floor. The idea of the prophylaxis in this particular instance is that it prevents damage to the baby's brain from prolonged pounding of the head on the pelvic floor and that it prevents the overstretching of the pelvic floor and the damage resulting from pounding. That is the prophylactic forceps operation.

DR. HARRIS J. TIMERMAN, Chicago: I wish to emphasize the simplicity of the local anesthesia procedures, especially the pudendal block. We found that inexperienced interns could readily be taught the procedure. I would caution that after the anesthetic has taken effect the patient loses most of her desire to bear down because of the deadening of the perineum and pelvic floor. She must be reminded frequently by the obstetrician if she is to expel her baby spontaneously. Fetal injuries were not included in the paper. There were but few. Three fractured clavicles occurred, one in a spontaneous delivery and two in breech extractions under general anesthesia. There were two fractured skulls and one of the two babies died. That baby was delivered spontaneously without anesthesia. The delivery was rapid. The autopsy revealed a fractured skull and cerebral hemorrhage. The other case was a depressed skull fracture occurring in a breech extraction under parasacral anesthesia.

FAVISM

AN UNUSUALLY OBSERVED TYPE OF HEMOLYTIC ANEMIA

JOHN E. HUTTON, MD

Associate Professor of Clinical Medicine, New York Post Graduate
Medical School of Columbia University, Associate Attending
Physician, New York Post Graduate Hospital

NEW YORK

Favism is a disease characterized by a rapidly developing anemia accompanied by jaundice, hematuria and hemoglobinuria, and owes its onset to the ingestion of the bean *Vicia faba* or to the inhalation of pollen from the blossoming plant. This bean seems to be a common article of food in the southern part of Italy, Sicily and Sardinia. Reports of the disease are not uncommon in the Italian literature and there are a few references to it, as fabismus, in the German. Although the beans are eaten by Italians resident in this country there seems to be little or no reference to it in English or American literature. A single case report of McCrae and Ullery¹ in 1933 and the following personally observed instance seem the only ones described in this country.

B. B., a man, aged 21, was admitted to the hospital complaining of weakness, a yellowish tinge of the skin and abdominal distress. The illness came on suddenly at a ball game and was attributed to a heavy meal taken just previously. The patient was indefinite about the presence of fava beans in this meal but had had them several times in the past few days. The patient thought he had experienced similar distress before but could not recall the exact circumstances. He had always been strong and in good health previously. There were no food intolerances, recurrent abdominal pains or other gastro-intestinal disturbances in the past history. He had suffered for two or three years from chronic sinusitis. The family history was given as negative. The father and mother were living and well. Two sisters had died in childhood.

From the Department of Medicine of New York Post Graduate Hospital.
McCrae, Thomas and Ullery, J. C. *Favism*. *J. A. M. A.* 101: 1389 (Oct. 28) 1933.

The patient was acutely ill. Though tanned, he showed definite icterus in the sclerae and soft palate. A postnasal discharge was present. The examination was otherwise negative except for a questionably palpable spleen. The fever was 104 F and the pulse rate 100. The urine was deep reddish brown, with a specific gravity of 1.012 and marked albuminuria, red cells were profuse, with many hyaline and granular casts. The benzidine reaction was 4+ on the urine. The Wassermann reaction was negative. The blood culture was negative. The stool showed a 4+ benzidine reaction. The hemoglobin was 32, red cells numbered 1,600,000, white cells 12,400, with polymorphonuclears 68 per cent, eosinophils 1 per cent, monocytes 2 per cent and lymphocytes 31 per cent. The smear showed anisocytosis. No malaria parasites were present. The bleeding and clotting times were normal. The icterus index was 30, the direct van den Bergh test was negative, the indirect van den Bergh 6 mg per hundred cubic centimeters. The blood showed nonprotein nitrogen 18.0 and sugar 121. The cholesterol was 202. Gastric analysis showed free hydrochloric acid present. The fragility of the erythrocytes was from 0.450 to 0.315. There was no bilirubinuria was present, 6 mg per hundred cubic centimeters. The Donath-Landsteiner reaction was negative.

A chest roentgenogram showed old puerile type tubercle foci. Gastrointestinal study showed moderate splenic enlargement, moderate antral hyperactivity and some duodenal stasis classed as functional in origin. Genito-urinary roentgenograms and cystoscopic study were negative. The gallbladder was free from disease and essentially normal to x-ray examination.

Later questioning revealed that the maternal grandmother, the mother and one of the mother's brothers had been repeatedly jaundiced at times.

The first impression was of an acute hemolytic anemia such as paroxysmal hemoglobinuria, hemolytic family icterus or chemical poisoning. There were, however, obvious contradictions to those diagnoses.

The course was as follows. For two days the complaints were of headache, weakness and unlocalized abdominal distress with general malaise. Marked anorexia was present. After that, fatigue was the only complaint. The patient was up in a chair fifteen days after admission.

The urine five days after admission showed albuminuria 1+, from 4 to 6 red cells per high power field and a few granular and hyaline casts. The benzidine reaction was still 2+. Ten days after entrance the urine was entirely normal. The hemoglobin and red cells fell to 32 per cent and 1,300,000 respectively four days after entrance. A few normoblasts and marked polychromasia were noted. After transfusion, on the eighth day in the hospital the red cells were 4,600,000, the hemoglobin being 70 per cent. A week later the hemoglobin was 80 per cent, red cells 3,900,000 and white cells 6,900. The reticulocytes were 12 per cent. After twenty-one days in the hospital the hemoglobin was 85 per cent and red cells 4,600,000, with normal smear. The fragility varied from 0.450 to 0.315 and from 0.495 to 0.315. The stools became benzidine negative after two weeks. The icterus index was 9 and the van den Bergh reactions were normal after six more days in the hospital. The blood nitrogen was normal after twelve days.

The therapy employed was a high protein diet, rest, ample dosage of ferric ammonium citrate and one transfusion of 500 cc.

The patient returned to the clinic one month after admission with the story of rapid gain in strength and no further gastrointestinal upset or abnormality of the urine. The color was good and the sclerae were clear. The hemoglobin was 95 per cent and the red cells numbered 4,600,000. The spleen was just palpable. In another week both the blood count and the patient were entirely normal and have remained so despite intercurrent infections of the upper respiratory tract, three nasal sinus operations and a mastoidectomy.

Attention to the case report of McCrae and Ullery prompted further investigation of the history with the following developments. The maternal grandmother had had several attacks of sudden weakness, pallor, jaundice and dark brown bloody urine. The acute picture lasted three or four days and was followed by

rapid recovery to the normal state. The mother had had similar attacks. The eldest brother had one attack of the same nature. The maternal great grandfather and his sister and all of her children had had attacks almost yearly in the spring during the fava season, all attacks being of a stereotyped nature. One of the maternal grandmother's children died in an attack, a neighbor having given her a few raw green fava beans to play with. These she ate and died in twenty-four hours with collapse and jaundice.

All of these familial attacks last about three or four days. There is jaundice, pallor, dark red urine and great weakness at the onset, with rapid recovery. There has been no asthma, rhinitis or urticaria of paroxysmal nature, either associated with the attacks or at other times, in members of this group. The attacks are attributed by the affected members of this group to the bean and are said to come when it is green and fresh. They are accepted as a penalty for partaking of the beans. After the beans are dry and brown they are said to produce disturbance no longer. In the Italian countryside of origin of this family group, poisoning was apparently common and was produced at times even by the "smell" of a field of growing beans.

When directly consulted, the patient's family readily agreed that the described attack in this patient was undoubtedly due to ingestion of beans.

Skin tests² performed intradermally with extracts of fava beans in amounts from 0.0001 to 0.1 mg were negative in this patient.

He has declined the suggestion of a trial ingestion of green beans at the proper season.

In the case of McCrae and Ullery, a man, aged 53, was first observed in a serious condition with pallor, jaundice, hemoglobinuria, tender liver and severe anemia. He was discharged in thirty-eight days with no jaundice and a normal urine. An extract of the fava bean in a dilution of 1:1,000 gave a positive skin test and caused malaise and backache for four days. This reaction was later duplicated. The patient had eaten a large meal of cooked fava beans five days before admission. An hour later he felt very weak and two hours later voided very black urine.

This syndrome is mentioned by ancient authors and has been reported as an idiosyncrasy since the middle of the nineteenth century. After an incubation period of from two to six hours with inhalation, and of from one to two days in ingestion cases, the symptoms begin. Occasionally they may develop much sooner. Chills, fever, vomiting, weakness, vertigo, tinnitus and loss of consciousness may occur. Marked pallor and jaundice, rapidly increasing to the third day, an enlarged and tender liver and often splenomegaly are noted. Biluria may be found and the urine constantly shows red blood cells and hemoglobin with albumin and granular casts. The hemoglobin and red cells fall rapidly, often to 20 per cent and 1,000,000 respectively. After an initial leukopenia there is a leukocytosis. The resistance of the red cells is normal and auto-agglutination is not found. Hemoglobinuria is not constant. The serum of patients is not hemolytic to their own cells or to the cells of others but the injection of such serum into rabbits produces hemoglobinuria and leukocytosis. Abortive and malignant types are observed. Death may occur from anemia (8 per cent in Sardinia). Usually in from two to four days the clinical picture improves.

The diagnosis is apparently easy in regions of common occurrence but is difficult elsewhere without the

² Performed in the Allergy Clinic through the kindness of Dr. W. C. Spain.

aid from the patient or relatives of a history of ingestion or exposure, especially in the abortive forms Malaria and paroxysmal hemoglobinuria can usually be excluded

As to therapy, epinephrine has been suggested for the early shock and transfusion of blood for the anemia. The administration of iron may expedite convalescence if the body iron reserves are depleted.

In about 20 per cent of cases a hereditary factor is present (as in allergy). In certain families every member for generations has been reported as severely affected. The individual susceptibility varies. After years of eating the beans with impunity, a severe attack may occur with subsequent freedom. The onset is usual in adult life and in old age. Ingestion by immune mothers may affect the suckling offspring. There is no sex predilection. In 1,211 cases, 38 per cent originated in inhalation from blooms and 62 per cent in the ingestion of raw or cooked beans. The prevalence of the condition apparently varies from year to year. It occurs oftenest following the first ingestion of the green bean in season, and in those who consume them infrequently.

The reaction is not due to foreign fungus contamination but to some of the substance of the bean. Animals can be sensitized by feeding or injection. Some authors hold that there is a state of hypersensitiveness to the bean protein and that the manifestations are due to an anaphylactic reaction. Only a few of those exposed to a single preparation of the bean will become ill and there is no quantitative relationship noted in its effect. Death may occur from a small quantity.

THE EARLY DETECTION AND TREATMENT OF DEFECTIVE HEARING IN CHILDREN

HORACE NEWHART, M.D.

MINNEAPOLIS

The purpose of this paper is to stress the importance of the early discovery of deficiencies of hearing in children by accurate methods recently made available, which make possible the more effective treatment of diseases of the ear resulting in defective hearing.

Otology has kept pace with other medical specialties in productive research, pathology, diagnosis and improved technic in the surgical treatment of complications involving the middle ear. Achievement in the prevention of deafness, however, when compared with accomplishment in other fields of preventive medicine, leaves much to be desired. Both the medical profession and the public have largely failed to appreciate the importance and magnitude of the problem of conserving the hearing, on which the individual to a great extent is dependent for his normal intellectual development, for the acquisition of speech and for maintaining his economic and social security.

The magnitude of the problem is indicated by the statement that 10,000,000 persons in the United States have a demonstrable deficiency of hearing, causing a recognized or potential handicap. Of these, 3,000,000 are school children, of whom 300,000 already are handicapped in their scholastic achievement.

Since a large percentage of all cases of impaired hearing are preventable by the application of knowledge now available to every physician, it may be stated without fear of contradiction that the ear, in proportion to its importance, is the most neglected organ of the body.

The attitude of the average person toward efforts to remedy this tragic condition has been one of indifference, owing chiefly to a lack of understanding of fundamental facts involved in the problem.

The pediatrician has been a notable and consoling exception. Through his interest and success in reducing the incidence of the contagious diseases of childhood, with their many complications involving the ear, he has rendered valuable service in lessening the incidence of deficiencies of hearing in his patients. His close contact with children has caused him to realize that his opportunities and responsibilities in helping to solve the problem of better hearing are often greater than those of the otologist.

Many factors, ordinarily overlooked, have caused the failure to secure more satisfactory results in this field of preventive medicine. Among them the following should be mentioned:

- 1 The inaccessible anatomic location of the ear has been a difficult barrier to otologic research, diagnosis and effective treatment of diseases of the ear causing defective hearing.

- 2 Because of the physiologic factor of safety, whereby man has been given a materially greater hearing acuity than is required to meet his ordinary needs in civilized life, a person may lose a considerable percentage of his hearing acuity without being conscious of his loss. This fact accounts for frequent neglect of the ears until it is too late to obtain the most satisfactory results from treatment and has been the foundation for the widespread, persistent, cruel fallacy to the effect that when once the ear has begun to deteriorate treatment is not worth while. This defeatist attitude has caused much needless deafness.

- 3 A most important factor has been the inadequacy of the older methods of testing hearing acuity to disclose a slight but significant loss of hearing. The presence of such a deficiency often is not recognized by the child himself, his parents or his teachers. It has only recently been shown that slight losses of hearing in school children cause retardation, speech defects, inferiority complexes and unsocial behavior.

The older methods, the watch tick, acoumeter, whisper and conversational voice, as ordinarily applied, have been too crude, inaccurate and time consuming to meet the requirements of modern otologic practice. In their application, until lately, certain fundamental acoustic principles which must be observed in order to insure accuracy in making tests of the hearing by any method have been overlooked.

- 1 No test of the hearing can yield accurate results when made in the presence of noises of sufficient intensity to mask the tones or the sounds used for testing. Such noises are especially disturbing in tests of children. They must be suppressed as far as possible at the source of origin and excluded from and absorbed by the walls of the space in which the tests are made by adequate acoustic treatment. Such treatment can be effectively applied for practical purposes at a moderate cost. Recently planned schools and medical office buildings are now constructed to reduce the level of noise to meet this need.

2 To avoid a common source of error, each ear must be tested separately. The ear not being tested must be excluded by some effective masking method.

3 Otologic practice today requires that for the purpose of accurate diagnosis, in distinction from screening, the physician shall be able to determine the threshold of hearing at different frequencies or pitches for both air and bone conduction.

The individual merits and shortcomings of the older tests are too many for enumeration here. However, I must protest against the frequently quoted, antiquated statement that "the ordinary-sized watch should be heard by the normal ear at 4 feet." With the great variation in the loudness and the pitch of the sound produced by different watches this is obviously untrue and, to the uninformed, is seriously misleading. Every watch used for testing hearing acuity must be calibrated by determining the distance at which it can be heard by the normal ear. This distance serves as the denominator of the fraction whose numerator is the distance at which the watch is perceived, the fraction expressing the hearing acuity.

An improved substitute for the watch, recently produced by Dr. Frederick N. Sperry, consists of a standardized stop-watch movement of relatively low pitch without face or hands. Unfortunately it is too loud to disclose a slight loss when used in a small acoustically treated room. The advantages of the Sperry tester commend it for use by the physician, the school and public health nurse and the teacher for roughly detecting and estimating the degree of a loss of hearing when better means are not available.

The cochleopalpebral test to determine total absence of serviceable hearing in infants and very young children, though not infallible, should be known to every pediatrician. A normal reaction consists of the quick, reflex blinking of the eyelids in response to a suddenly made loud noise.

Accurate detection of a slight or moderate hearing deficiency in the infant or very young child is impossible. The presence of mouth breathing, pathologic cervical glands, cleft palate, frequent infections of the upper respiratory tract, failure to talk at the normal age and unresponsiveness to speech and noises should cause one to suspect defective hearing. Children over 4 years of age by training can be conditioned to respond to various tests for an approximate determination of the degree of hearing acuity they possess. In testing the hearing of young children one should never forget their inability to concentrate the attention for any sustained period. The acoumeter, the accentuated whisper and the conversational voice are all too loud for the accurate detection of slight degrees of impairment of hearing. Only the suppressed whisper, and not the "stage whisper," as erroneously stated in some textbooks, should be used for disclosing a slight loss of hearing.

Tuning forks, when properly calibrated as to their decibance, when struck with a uniform blow and when used in a place affording sufficient quiet are valuable for determining the presence, type and degree of loss of hearing when the saving of time is no object.

The one most effective measure for actual accomplishment on a large scale in the field of prevention of deafness is the regular, periodic testing of the hearing of children during the school age. Then large numbers are kept under close supervision can be accurately tested in groups by screening methods for the purpose

of detecting those having a significant defect, and are available for frequent observation. The best results from preventive and corrective treatment are possible at this age.

The early detection of deficient hearing, accurately made as a regular part of the school health program, has definite objectives.

1 To provide that the child with defective hearing shall receive whatever special educational care and adjustment his condition requires in order that he may have equal opportunity with the normally hearing child.

2 To make possible the earliest application of medical or surgical corrective treatment that may be necessary to improve or maintain his hearing acuity.

3 To safeguard him against the possible burden of a severely handicapping loss of hearing in later life from causes which, on the basis of extensive clinical observation, now are known in many cases to have their origin in pathologic conditions present in childhood, such as inflammatory disease of the nasopharynx, tubotympanitis, pathologic adenoids, tonsils and nasal sinuses and many other diseases.

Audiometers of different types afford the most accurate and practical means of detecting and measuring impairment of hearing. The 4-A audiometer, in its improved form known as the 4-B, or phonograph audiometer, is used for screening purposes. With it, a maximum number of forty pupils who are old enough to write dictation are simultaneously tested. By this means three or four times as many pupils are discovered to have loss of hearing as were revealed by the older methods.

Younger pupils and preschool candidates for the Summer Roundup sponsored by the National Congress of Parent-Teacher groups can be individually tested by a modified application of the phonograph audiometer. In New York State since 1928, on the recommendation of Emily A. Pratt, M.D., of the New York State Education Department, the 4-A audiometer has been used for testing younger pupils individually. Miss Olive Burdge of Cincinnati, principal of the Oral School for the Deaf, successfully uses the phonograph audiometer for testing young children in groups by a method called the Cincinnati telephone game, in which the children whisper to assistants the numbers they hear. Preschool children and children in the lower grades can also be individually checked by the 2-A or the 6-A audiometer or any one of several other pure tone audiometers, used for diagnostic purposes, recently made available at a cost less than that of the original 2-A instrument.

The regular, periodic testing of all school children by scientifically accurate methods was endorsed first by a resolution of the House of Delegates of the American Medical Association in 1926 and later by many other national and state medical organizations.

The federal government two years ago gave its unqualified approval by helping to underwrite WPA project 188-1177, providing for a comprehensive survey including the medical and statistical follow-up of 1,000,000 children in public and parochial schools in New York City. In 1936 the New York legislature passed a law making mandatory the audiometric testing of all school children. In the same year a bill was passed requiring that all school children in the state of New York having a loss of hearing be reported by the attending physician, nurse or other person responsible through the local health officer, to the state health

department In 1937 a law was passed in New York creating a temporary commission to study hearing conditions among preschool and school children

During the present year legislation for the prevention of deafness and for the better care of the deaf and hard of hearing was considered or passed in several states, including California, Iowa, Minnesota, New Jersey, Oklahoma and Pennsylvania¹ This successful and attempted legislation is a fine evidence of a rapidly growing interest in the problem of better hearing

Audiometer tests during the past ten years, as a part of the school health program have been carried out in many widely separated communities in the United States with very satisfactory results A striking result of the consistent use of the audiometer over a ten year period in the Minneapolis public schools is the notable reduction in the incidence of significant loss of hearing in the school population from 8 per cent to 5.3 per cent

In the adjacent rural districts, the same screening methods being used, in a survey made as a University of Minnesota WPA project, the incidence of significant loss of hearing was found to be 13.6 per cent Using the older methods, Minnesota public health nurses found a corresponding loss of only 2.2 per cent in rural school children These figures indicate the urgent need of a better school health program in rural areas This can be provided in many country districts only through the help of federal or state aid

The educational care of the child having a deficiency in hearing calls for the understanding guidance of the teacher, the assignment of a classroom seat most favorable for hearing and speech-reading and, if the loss is greater than 20 decibels in the better ear, for special instruction in lip reading and speech correction, if needed A last step for the severely deafened child is enrolment in a special class for the hard of hearing in a residential or day school, to be continued only for such a period as will give sufficient skill in lip reading and voice training to enable the child to continue his schooling with normal children To educate a hard of hearing child with deaf children is a grave pedagogic error

The use of modern individual and group hearing devices is of great help to the child having a loss of hearing of 40 decibels or more in the better ear if, on thorough trial, it materially increases his ability to interpret articulate speech All children of kindergarten age or older having a defect which can be materially compensated by a hearing device should be given the benefit of such an aid The use of a hearing device by the child with a handicapping loss of hearing will in the near future probably be as common as is the use of corrective glasses by the child with a visual defect causing an equal handicap

The depression and the high cost of the needed equipment have definitely delayed the more general adoption of the audiometer in school health work Recently the price of audiometers was materially reduced Experience has shown that the cost of regularly testing the school population with the audiometer is more than compensated by the saving effected through reducing the number of repeaters due to defective hearing It has been estimated that a program including the early discovery and the medical

corrective treatment of defective hearing, instruction in lip reading, the use of electrical hearing aids and favorable seating for the hard of hearing pupils will reduce by 50 per cent the amount of retardation This would result in a saving of at least \$3,600 per thousand pupils

The medical treatment of children with defective hearing begins with notification of the parents of the discovery of the loss of hearing and the recommendation that the child be given a thorough medical and otorhinologic examination by the most skilful physician available The medical care of the indigent should be the responsibility of the local members of the medical profession While it is eminently in order that the screening tests be made by the school nurse teacher or technician, this work should be supervised by qualified physicians The medical care of children having defective hearing consists of the application of such corrective medical or surgical treatment as is indicated by the results of the examination and is in accordance with the latest teachings of otology In the accurate diagnosis of a lesion of the ear, determination of the threshold of hearing, for both bone and air conduction, at various frequencies by a reliable audiometer is desirable

Modern otology has shown that defective hearing in children often results from pathologic conditions in parts of the body other than the ear itself Dr E P Fowler and others have reported the frequent coexistence of sinusitis and inflammatory disease of the ear in children A tendency to repeated colds and nasopharyngitis is a common cause of otitis media Likewise faulty methods of swimming and diving as well as prolonged exposure of the body to cold water produce inflammation of the tube and middle ear, as pointed out by Dr H Marshall Taylor, chairman of the American Medical Association Committee on the Otorhinologic Hygiene of Swimming Malnutrition, a deficient diet, endocrine imbalance, allergy, anemia and various systemic diseases are all recognized causes of diminished hearing acuity According to Taylor the effects of chenopodium, salicylates, quinine and many other drugs in susceptible persons produce a loss of hearing acuity He also suggested that the administration of certain drugs to a pregnant woman may cause deafness in the new-born child

A cause of loss of hearing in children which too often is overlooked is the frequent recurrence of adenoid masses or adhesions adjacent to or about the pharyngeal cushions of the auditory tubes, whose function their presence often impairs Chronic suppurative otitis media because it not only causes loss of hearing but because it is a constant menace to life itself should never be neglected

Many perplexing cases of insidiously increasing loss of hearing from obscure causes may be solved by the cooperation of the otologist and the pediatrician, together with the occasional help of consultants in other highly specialized fields of medicine Modern otology is rapidly becoming less tolerant of the defeatist attitude, as our knowledge of the causes of diseases of the ear resulting in loss of hearing increases

CONCLUSIONS

1 Accurate periodic testing of the hearing by modern scientifically approved methods is necessary for the early discovery, diagnosis and successful treatment of many diseases of the ear which result in impairment of hearing

¹ Since the paper was read Pennsylvania has passed legislation similar to that of New York State effectively providing for annual audiometer tests of all school children and for the necessary educational and medical follow up

2 The incorporation in the school health program of the regular periodic testing of hearing of all school children has proved to be the most effective single procedure for reducing the incidence of loss of hearing

3 There is urgent need for the enactment of federal and state laws which will make possible the incorporation in the public school health program of periodic audiometric tests of all school children, especially in rural areas

4 Increasing interest in the health of the preschool child is a special challenge to the pediatrician, since he has the first opportunity to determine the presence of diseases which threaten the integrity of the organ of hearing

78 South Ninth Street

ABSTRACT OF DISCUSSION

DR AUSTIN A HAYDEN, Chicago Let me first express the appreciation of the Committee on Deafness Prevention of the American Academy of Ophthalmology and Otolaryngology for the inclusion of Dr Newhart's paper, "The Early Detection and Treatment of Defective Hearing in Children" in a pediatric program. The conservation of hearing begins long before we are born and ends only on the postmortem table. Obviously the entire life span of the conservation of hearing can be touched on only at its highest spots. Modern genetics definitely points to a close relationship of certain types of loss of hearing (otosclerosis) with the family history of the individual. Post-mortem examination of ears will lead great assistance to the problem that Dr Newhart has brought before this section. I am not so optimistic as to believe that any number of pediatricians will buy audiometers or use tuning forks in a routine way. In the emphasizing of these new methods I make a plea that the older methods, including the careful attention to the case history, the statements of the parents and other people that come in contact with the child are not to be overlooked. Neither are the whisper, the watch tests and the tuning forks to be done away with. But all these should be properly correlated in a sort of universal screening test by any method whatever that is readily available, because almost any method is better than no attention to the ears at all. When the children with defective hearing have been selected by any of the foregoing means, individual tests of the 4 or 5 per cent of children in public schools that these tests show to have loss of hearing should be conducted to an otologist's office. No one has done more for the perfection—indeed very few as much—of these procedures and the plea for their universal adoption than has Dr Newhart.

DR LEO S FRIEDMAN, Cincinnati I congratulate Dr Newhart on his excellent presentation of a very timely subject. I am from a city which has been taking a leading part in this work. Largely through the interest of Drs McCarthy and Howard, Cincinnati is doing her share in the early detection and correction of hearing defects in children. About 12,000 hearing tests are carried out each year, which reveal about 900 children with hearing defects. Of this number, 500 are referred to private physicians and the remainder to a well organized clinic under the guidance of experienced workers. The latest reports indicate that approximately 52 per cent of these defects have been corrected. But valuable as this work is, I believe we are not getting at the cause sufficiently early, that is, in the infant and the preschool child. Of course it is realized that audiometer tests cannot be carried out until after 4 years of age has been reached. Particular care must be taken with regard to the nutrition diet and hygiene of infancy. Many young babies who regurgitate their feedings through the nose and are allowed to remain on their backs may be predisposed to ear infections and thus to hearing defects. Repeated evidence of this has been found in very young babies. Immunization against the preventable diseases, such as measles, diphtheria and scarlet fever and the early treatment of syphilis meningitis and the like will go far in the solution of this problem. The early use of such agents as immune globulin represents valuable aid in the prevention of defects of hearing.

MYXOFIBROMA OF THE SPERMATIC CORD, POSSIBLY NEUROGENIC

REPORT OF A CASE

ABRAHAM L VOLBARST M D

NEW YORK

Compared with the frequency of cysts of the spermatic cord which are fairly common,¹ tumors are quite rare. In 1934 Burr,² reviewing the literature on cord tumors, found a total of 219 reported cases, including two which he then reported. Two years later, however, Thompson,³ again reviewing the literature on the subject, found a total of 216 cases after eliminating a few which he thought were subject to doubt.

Burr classified the 219 growths on the basis outlined by Hinman and Gibson⁴ as follows: lipomas, 58; embryomas, 47; fibromas, 28; sarcomas, 27; dermoid cysts, 21; connective tissue cysts, 14; angiomas, tumors, 6; unclassified, 6; myxomas, 5; myomas, 5; tumors of the wolffian body, 2; total, 219.

Hinman and Gibson conclude that of all tumors of the cord, epididymis and testis 90 per cent occur in the cord, of these fibroma constitutes about 11 per cent.

It will be seen that twenty-eight cases of cord fibroma have thus far been reported.

Patel and Chaher⁵ and Rubaschow⁶ made extensive studies of cord tumors. They conclude that fibroma seems to originate in that portion of the spermatic cord which is near its junction with the epididymis, and they arise from the connective tissue which unites the various elements of the cord at that point. They are slow growing and cause no symptoms other than the swelling. The majority of patients give histories of having noted the tumors for a number of years before seeking medical attention. The average interval is six years. The tumors are usually benign.

While twenty-eight fibromas and five myxomas of the cord have been reported there is no mention in Hinman and Gibson's classification of myxofibroma, of which three cases have thus far been reported. In the present contribution, a fourth case is reported.

REPORT OF CASE

H K, a man aged 55 complained that he had had an annoying sensation (not a real pain) in the left side of the scrotum for about one year. His general health was excellent. He was somewhat nervous and he was a persistent golfer, but there was no history of trauma or serious illness. The first physician whom he consulted said that he had a hernia, for which he prescribed a truss which was worn for several months without benefit. Another physician told him that the trouble was mental but even that did not help him. The annoying sensation persisted.

Fig 1—Gross specimen of tumor

- 1 Wolbarst A L Urol & Cutan Rev 15 1920
- 2 Burr G C Grace Hosp Bull 18 4 1934
- 3 Thompson C J Surg Gynec & Obst 62 72 (April) 1936
- 4 Hinman Frank and Gibson T E Tumors of the Epididymis Spermatic Cord and Testicular Tumor Arch Surg 8 100 (Jan) 1924
- 5 Patel and Chaher J Clin Path 1949
- 6 Rubaschow S Ztschr f Urol 120 14 21 42 1926

On examination, Jan 12, 1937, a mass was observed attached to the left cord about midway between the external ring and the epididymis. Though it was not translucent it was believed to be a cyst. Excision was advised and performed February 26 a local anesthetic being used. On exposure the tumor, approximately the size and shape of a large green olive, was found attached to the tissue elements of the cord by a broad base.

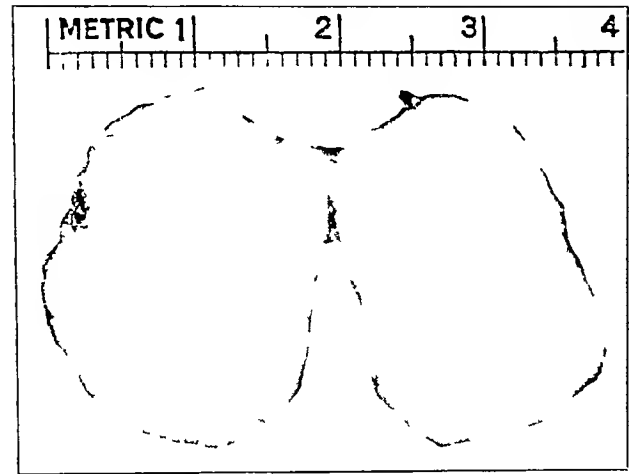

Fig 2—Transverse section of tumor

Apparently all the cord elements were fused together at that point by inflammatory tissue. The vas deferens lay posteriorly and appeared to be closely adherent to the rest of the cord. It was impossible to determine any particular tissue from which the tumor derived. The tumor was dissected from its adherent base with little difficulty; bleeding was slight. The wound was closed and the patient made an uneventful recovery. Four months after operation he reported feeling well with complete disappearance of the annoying sensation in the scrotum.

On gross examination the tumor was firm and solid and rather whitish. The pathologist made the following report:

"Tissue from the spermatic cord on macroscopic examination measured 3 by 2 by 1 cm. It weighed 4 Gm. It was nodular and on cut section was solid and showed whorls of connective tissue and had a definite capsule. There were areas that had a glazed appearance."

Microscopic examination revealed a tumefaction that was composed of clumps of elongated nuclei in cells of the neurilemma type which were in a palisade arrangement. Frequent myxomatous areas were present. There was a definite capsule present in this tumor. There were no histologic characteristics present which denoted where the tissue arose.

"The diagnosis was neurofibroma of the spermatic cord."

Since neurofibroma of the cord has never been reported, it was considered essential to have this pathologic diagnosis confirmed before it was accepted as final. The specimen was therefore submitted to Dr. Alfred Plaut, pathologist of Beth Israel Hospital, whose report follows:

Gross Examination—Ovoid, firm (previously fixed), seemingly capsulated nodule, 3 by 2 by 1.5 cm. The cut surface in the present condition of the specimen is pale gray with some indistinct water-silklike markings.

Microscopic—The picture mainly is that of a partly edematous fibroma. In some portions the connective tissue fibers are thick and coarse with relatively few nuclei; in others, notably the edematous ones, they are very fine. Further differences are caused by the irregular distribution of inflammatory processes. Round cells, small and medium sized ones, are accumulated in the adventitial tissue of blood vessels. There are round aggregations of such cells in different portions, and there are some more diffuse infiltrations. In the highly edematous areas the connective tissue cells have assumed rather irregular, partly starlike shapes resembling myxomatous tissue.

The mucicarmine reaction is not very distinct. All the coarser fibers and most of the fine ones become definitely red in the van Gieson stain. No structures suggestive of nerves or undifferentiated nervous tissue can be found. The irregular wavy character in some portions is best explained by the edema. The same applies to the unusually large and irregularly shaped cells which, to repeat it, are found only in edematous areas.

Diagnosis—Partly edematous fibroma.

"Since no normal tissue is found, no definite statement can be made about the origin of the tumor. In the scrotal region the possibility of a postinflammatory condition always has to be considered. No definite evidence for such an origin is found in the specimen. Another possibility in this location is that of an originally mixed tumor with one-sided development."

There were thus two conflicting diagnoses, the point at issue being the nature of the many fine fasciculi—whether they were true ganglion cells or merely inflammatory or edematous products. To settle the question, Dr. James Ewing kindly consented to study the slides, with the result as shown by his reports that the nature of the growth still remained without a definite diagnosis. Dr. Ewing's reports follow:

May 10, 1937: "Your tumor from the spermatic cord is difficult to interpret. There are two possibilities: neurofibroma and a tumor of the cremaster muscle. I do not find satisfactory evidence of a neurogenic origin, although in one of the smaller sections the periphery of the tumor is highly fibrous and suggests the epineurium of a nerve trunk. It may also be nothing more than the capsule laid down around a tumor of some other origin. In some points there are fasciculi which commonly resemble neurofibroma. There is also much hyaline keloidal material which suggests a nerve origin. Neither of these features is sufficient to prove a neurogenic origin."

On the other hand, the whole structure is just as well derived from muscle tissue and the mucous character with

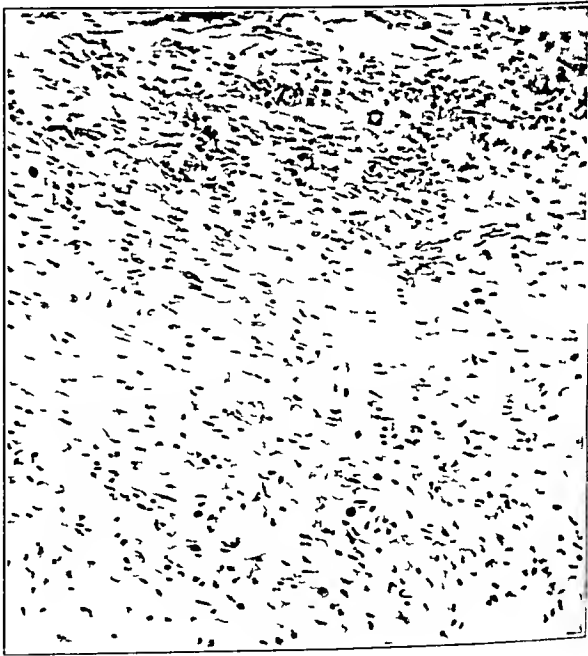

Fig 3—Section under low power X 180

marked edema as well as the fasciculi are sometimes seen in muscle tumors. I cannot positively identify any muscle elements, but there are very suggestive features of muscle relations. Most of the tumor is inflammatory in origin with marked edema. Since silver stains only show I do not think it will help in making our diagnosis. We will put through some silver stains and then add any information I will let you know. At present I presume we will have to call it low grade hyaline myofibroma, not malignant, but I cannot

positively exclude a neurogenic origin. Muscle tumors are rather common in the cord, and neurofibroma very rare.⁷

The second report from Dr. Ewing, dated May 25, follows:

The various specimens stained from your tumor of the spermatic cord, including selective H and E, van Gieson and silver, fail to show any specific features which help the diagnosis. I can find no special nerve fibers, but one would hardly expect to find them in a tumor so well differentiated. The fibers do not show any definite qualities of muscle. They are all collagenous. There are quite a few very large multipolar cells, some of which look like ganglion cells, but I do not think they can be identified as such. The exact nature I cannot determine. This leaves us without a positive diagnosis of any sort except myxofibroma.

The evidence of anatomic position is of first importance under such circumstances. Was the tumor connected with the vas deferens or the cremaster muscle or the fat tissue? At present all I can say is that you have a myxofibroma of benign character and undetermined origin.⁸

The tumor was studied as a matter of interest by a fourth noted pathologist, Dr. Paul Klemperer of Mount Sinai Hospital, who reported (verbally) that he agreed in general with Drs. Plaut and Ewing and expressed the opinion that the fasciculi were fibroblasts, despite their strong resemblance to ganglion cells. On the verbal advice of Dr. Ewing the tumor is therefore reported as a myxofibroma possibly neurogenic.

COMMENT

The various diverse opinions on the nature of this tumor offered by the four eminent pathologists who studied it emphasize the fact that it is frequently difficult for pathologists to agree on the proper category of a given tumor. The main question involved in this case was the interpretation of certain tumor elements which suggested a neurogenic origin. Microscopically, according to Karsner,⁷ "the neurofibroma often resembles the fibroma but is likely to show many delicate fibrils and small whorls of cells and fibrils. In many neurofibromas there are rows of cells with palisade arrangement of nuclei and an intervening band of parallel wavy fibrils."

Reference to the photomicrographs distinctly shows the presence of structures resembling spindle cells with wavy nuclei and intervening myxomatous tissue which might very readily be suggestive of a neurogenic basis. It will be observed that Dr. Ewing says that he cannot positively exclude a neurogenic origin of the tumor. In his reports he mentioned several features which suggest a neurogenic origin. 1. In one of the smaller sections the periphery is highly fibrous and suggests the epineurium of a nerve trunk. 2. In some points there are fasciculi, which commonly resemble neurofibroma. 3. There is also much hyaline keloid material, which suggests a nerve origin. 4. There are a few very large multipolar cells, some of which look like ganglion cells. While he did not feel justified in making a definite diagnosis of neurofibroma on this evidence, he did not exclude it—a fact of much significance.

The site of the tumor, far removed from a nerve trunk, would seem to eliminate a neurogenic origin, but, as Boyd⁸ says, "in neurogenic fibromas it is often impossible to detect any apparent connection with a nerve of some size." With these facts in mind one cannot ignore the possibility of a neurogenic origin of this tumor (neurofibroma), though I accept the diagnosis of myxofibroma because of the preponderance of expert opinion.

A careful search of the literature reveals reports of three myxofibromas to date, but a possible neurogenic origin is not involved in any of these cases. They were reported respectively by Goodhart,⁹ Mayer,¹⁰ and Starlinger.¹¹ The present case is the fourth myxofibroma of the cord thus far reported, and the first with a possible neurogenic origin.

SUMMARY

The myxofibroma of the spermatic cord here reported presents unusual features and is apparently the

Fig. 4.—Section indicating possibly neurogenic elements. $\times 450$.

fourth case recorded, if certain suggestive elements were accepted as of neurogenic origin the tumor would be classified as a neurofibroma of the cord—the first case to be recorded.

Methods of Attack on Noise Abatement—The first line of attack on noise abatement and in general, much the most effective and economical, is to tackle an objectionable noise at the source and find the best means of reducing the output as much as possible. The next step, possibly as a confession of failure, is to find a feasible method of confining or smothering the noise in the place where it is generated. In either case we turn to the engineer for help and we may anticipate that he is likely to be the more interested if he can see a potential demand from the public.—Kave G. W. Clinical Notes, Suggestions and New Instruments

GANGLIONS OF TENDON SHEATHS

A METHOD OF TREATMENT

CARL BEARSE M.D. BOSTON

While ganglions may disappear spontaneously, years sometimes elapse before this takes place. One patient, a physician, had a ganglion for ten years before spontaneous rupture occurred. Since ganglions usually occur on the wrist and are embarrassing deformities, and since they may also cause discomfort most patients prefer prompt treatment.

Of the many methods that have been advanced in the past for the treatment of ganglions the one that has been generally accepted is excision.¹ It is obvious that the simpler methods that have been recommended—that is, forcible rupture with a heavy object such as a book, puncture with a hypodermic needle, injection of an irritant such as iodine, scarification of the walls of the sac, and the like—are not always successful otherwise operation would not be advocated.

The pathogenesis of ganglions is not too well understood, the commonly accepted theories are that they may be due to a herniation of synovial membrane through a rent in a tendon sheath, that they may be due to colloid degeneration of a synovial fringe inside a tendon sheath or that they may be due to cystic degeneration of an area of connective tissue adjacent to a joint or a tendon. They occur most commonly in people who have constant wrist and finger motion, as for example typists, pianists and washerwomen, and they may follow an injury or strain. Therefore, unless there is a change in occupation or no further strain or trauma, the likelihood of further ganglion formation must be considered.

Excision however, is not the ideal treatment. While it does permit the complete removal of a ganglion, it does not remove the possibility of further ganglion formation. Moreover, excision carries with it objections inherent to any operative procedure, except possibly to a lesser degree. Should there be a recurrence or should ganglions appear at other sites, operation may again have to be done.

While puncture of a ganglion with a hypodermic needle was one of the methods advocated in the past the results were not satisfactory since the thick gelatinous contents of the ganglion could not be thoroughly evacuated. I have found that puncture of a ganglion with a large bore needle such as that used in blood transfusions is always effective. It not only ruptures the ganglion but at the same time permits the complete evacuation of the sac. Following puncture and evacuation, a tight bandage is applied for twenty-four hours. Should recurrence or further ganglion formation take place this treatment by puncture can be repeated as often as necessary. As a result of this method of treatment the discomfort to the patient is minimized, the drawbacks of operation are avoided and there is no scarring.

REPORT OF CASES

The following cases illustrate the value of this method.

CASE 1—Mrs D L, a housewife, aged 30, had a ganglion the size of a marble on the dorsum of the left wrist for three months. It was punctured March 7, 1928 and as late as April 17, 1937, nine years afterward there had been no recurrence.

CASE 2—Mrs N C, a housewife aged 27, had a ganglion the size of a marble on the dorsum of the right foot for six months. This was punctured June 23, 1928, and by April 16, 1937, almost nine years afterward there had been no recurrence.

CASE 3—Mrs D K, a housewife aged 32, had a ganglion the size of a large pea on the ventral surface of the left wrist. The ganglion was punctured Sept. 20, 1928 and by April 21, 1937, almost nine years later there had been no recurrence.

CASE 4—Mrs P H, a housewife, aged 35 had a ganglion on the right wrist of two years' duration. The ganglion was the size of a cherry. It was punctured July 7, 1932. The following December it recurred and was larger than before. It was punctured again, with no recurrence up to April 16, 1937, almost five years later.

CASE 5—Miss S K, a commercial student, aged 19 had been operated on two years previously for a ganglion on each wrist with resulting scars. Several months after excision further ganglions appeared. At examination, Sept. 13, 1935 she had three ganglions of the left wrist and one of the right which were punctured. When seen four months later she again had a ganglion on each wrist, these were also punctured. Eight months later another ganglion appeared on the left wrist which was likewise punctured. When last seen, in March 1937 three months later, there had been no further ganglion formation. These ganglions always appeared at different locations on the wrists.

This patient continued with her daily typing after each treatment by puncture. Seven ganglions in all were punctured without the scarring, inconvenience, expense and risk that would have followed operations.

CASE 6—F F, a schoolgirl, aged 13 years, had a ganglion the size of a filbert on the left wrist. This was punctured Jan. 22, 1934, as late as April 16, 1937, more than three years afterward there had been no recurrence.

SUMMARY

1 Puncture of ganglions with a large bore needle such as used in blood transfusions is advocated.

2 This ruptures the sac and permits complete evacuation of the thick gelatinous contents of the ganglions.

3 Excision of ganglions, with the drawbacks inherent to any operation and its resulting scar is not necessary.

THE USE IN ARTERIOGRAPHY OF SUBSTITUTES FOR COLLOIDAL THORIUM DIOXIDE

CLARENCE E. BIRD, M.D., LOUISVILLE, KY.

In the two cases here presented roentgenographic visualization of the arteries and veins in the region of arteriovenous fistulas was obtained by the use of diodrast, one of the iodine containing solutions manufactured primarily to be used in excretory urography.

CASE 1—A Negress aged 17 years was stabbed in the upper third of the left arm with an icepick, Sept. 14, 1936. Almost immediately a thrill and a loud continuous bruit with systolic accentuations were found present over the medial surface of the swollen and ecchymotic arm. The radial pulse on this side was weaker than on the other. Five days later the circumference of the left arm 15 cm. above the olecranon was 25 cm., and of the normal arm 20 cm. The venous pressure on the left was 235 mm. (1 per cent sodium citrate) on the right 60 mm.

Nine days after admission, the brachial vessels were occluded above the fistula by digital compression, and 10 cc. of diodrast was injected into a vein in the cubital fossa. The roentgenogram taken immediately afterward is shown reproduced as figure 1. The region of the fistula is at the top of the film where the radiopaque fluid extravasated into a false aneurysm. The lower portion of the basilic vein and the venae comitantes of the brachial artery are well shown. The brachial artery itself is visualized from the region of the fistula to well below its bifurcation into ulnar and radial arteries. Several other smaller veins and arteries are seen, one of which is probably the profunda brachii.

Suddenly, on the tenth day following the injury, the arm became tensely swollen and painful. Evidently a large false aneurysm had formed. Operation was done with the patient under cyclopropane anesthesia a tourniquet being held high on the arm by transfusion pins. The basilic vein was found

uninjured. A large amount of blood clot was removed from around the median nerve and brachial vessels, and the brachial artery and vena comitans were ligated individually and divided at the site of the injury, about 2 cm below the origin of the profunda brachii artery. The opening in the side of the artery was seen, but the orifice into a vein could not be located. The wound was left dry and closed anatomically without drainage, fine interrupted silk sutures being used.

The radial pulse was palpable but weak immediately after the operation. There was no further circulatory disturbance and the wound healed by first intention. A venous pressure determination on the day of discharge, October 8, was 150 mm in the left arm and 65 mm in the right.

CASE 2—A Negress, aged 11 years, a ward of the Kentucky Home Society, admitted to the hospital March 15, 1937, had stepped on a nail four years previously. The child pulled it out and iodine was applied at the point of entrance. Three days later the bottom of her foot swelled and remained swollen. Two years later the prominence had increased and for the past year she had walked with her foot inverted because of tenderness over the mass. The history was otherwise irrelevant.

Fig 1 (case 1)—Brachial arteriovenous fistula visualized by a solution intended for excretory urography (diodrast).

gram of the chest were negative and the electrocardiogram was normal. The arterial pressure readings were right arm 102 systolic 60 diastolic, left arm 110/80, right leg, 140/90, left leg, 140/110. There was no bradycardiac reflex. Blood aspirated from the swelling was bright red.

A roentgenogram showed a soft tissue mass on the plantar surface of the right foot. The bones appeared normal. March 25, with the patient under light ether anesthesia, the right posterior tibial artery was isolated. With the cuff of a sphygmomanometer inflated to 200 mm of mercury below the knee 10 cc of diodrast solution was injected and a roentgenogram was taken immediately. The film obtained is shown in figure 2, in which the anterior and posterior tibial arteries, the plantar arch and the veins filled through the fistula are seen. The exact point of the fistula is not apparent but it is in the region of the plantar arch.

Shortly afterward with the patient under ether anesthesia and with the field made dry by a sphygmomanometer cuff on the leg a curved incision was made along the medial side of the foot and a flap of skin and subcutaneous tissue was

turned back down to the plantar fascia. There were huge dilated veins in the superficial plantar tissues which emerged through small openings in the plantar fascia. The fascia was divided by an L-shaped incision, exposing the flexor digitorum brevis. This was divided transversely and the ends were retracted. By careful dissection the sacculated, irregularly thickened veins were displaced, allowing the retraction of the plantar nerves. The partial division of the anterior portion of

Fig 2 (case 2)—Injected arteries and veins before operation in the region of a plantar arteriovenous fistula.

the quadratus plantae and the retraction medially of the flexor digitorum longus and the adductor hallucis muscles. The plantar arch and the mass of veins firmly attached to it by old fibrous tissue were excised. The sphygmomanometer cuff was released. The field was made dry and the parts were approximated anatomically without drainage, with fine interrupted silk sutures. The wound healed by first intention and there was no disability of the foot.

An arteriogram made May 1, three weeks after operation (fig 3), showed deficiency in the plantar arch and no filling of the veins.

COMMENT AND CONCLUSIONS

Because of the possibility that the injection of radioactive thorium dioxide solution may cause late toxic symptoms

Fig 3 (case 2)—Arteriogram after excision of the fistula.

colloidal thorium dioxide (thorotrast) has not been used in our hospital except for experiments on animals. Although several years have elapsed without evident harm to the first patients injected with colloidal thorium dioxide, those who recall the delayed symptoms of toxicity in the workers engaged in painting watch dials with a solution containing mesothorium will prefer to use other materials for arteriography. The present stand of the Council on Pharmacy and Chemistry of the American Medical Association with regard to the use of

thorium dioxide is to be found in a recent editorial.¹ A more detailed statement was published in 1932.²

Diodrast, neoskidan, uroselectan and similar preparations made for excretory urography are nontoxic in the doses used and are quickly excreted from the body. They do not damage the intima of the vessels and do not cause pain on intravascular injection (as does sodium iodide).

The density of the shadow cast by diodrast and similar iodine-containing solutions when utilized for arteriography is not quite so striking as with colloidal thorium dioxide. However, the visualization is entirely satisfactory, as may be seen in the illustrations. These should be compared with roentgenograms pictured in the articles of Horton,³ Yater,⁴ and Veal and McCord,⁵ who are the chief advocates of the use of colloidal thorium dioxide.

SIGNIFICANCE OF TRAUMA AND INFECTION IN THE SYNCYTIAL REACTION OF PREGNANCY

ROGER M. CHOISSER, M.D. AND BERNARD NOTES, M.D.
WASHINGTON, D. C.

The response of the endometrium to hyperestrogenism and normal pregnancy is well known. In some instances, however, this response is so excessive as to simulate neoplasia and particularly chorionepithelioma. Recently it has been pointed out¹ that in the presence of experimental hyperestrogenism associated with trauma to or infection of the endometrium an

Fig. 1—Syncytial cells in mucosa and superficial myometrium $\times 200$

atypical and exaggerated response follows. The case in question illustrates the combined effect of these three factors on the human endometrium: (1) hyperestrogenism, (2) trauma and (3) infection in the production of a syncytial response so unusual as to arouse serious suspicions of the presence of a chorion

epithelioma. The histologic differentiation of atypical syncytial reactions from true chorionepithelioma is frequently difficult and often the distinction can be made only on the basis of gonadotropic hormone studies.²

REPORT OF CASE

Mrs. H. D. M., aged 28, white, was referred to one of us (B. N.) Nov. 23, 1936. The previous family and personal

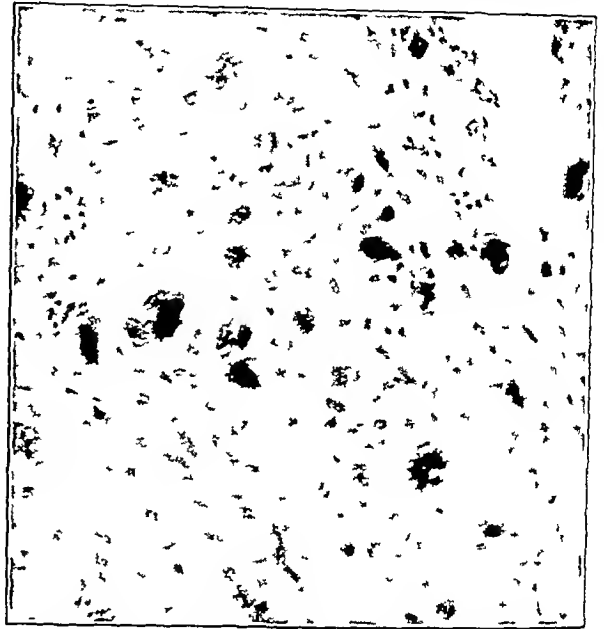

Fig. 2—Underlying myometrium densely infiltrated with multinuclear trophoblastic and foreign body giant cells $\times 200$

history were irrelevant, aside from the fact that a gold stem pessary (for contraception) was inserted into the uterus in 1930, removed and cleansed every three months during 1930 and 1931.

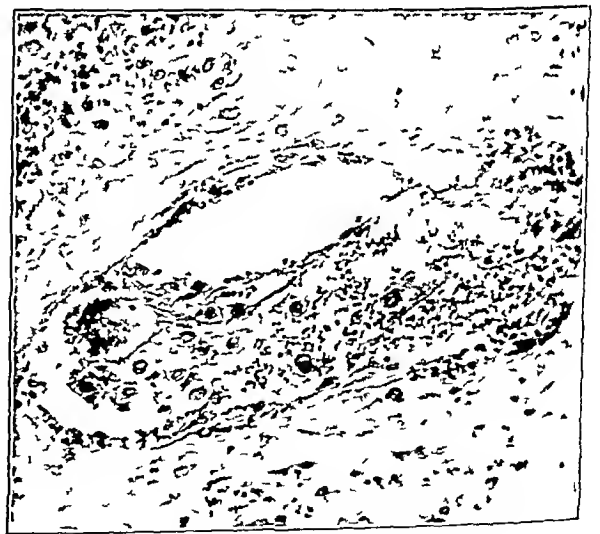

Fig. 3—Diffuse decidual reaction showing invading Langhans cell hanging in clusters within the vessel lumen $\times 200$

and left in situ during 1932 and 1933, a total of about four years. She had noticed no abnormal symptoms of any kind and had had normal menses during this four-year period. She began to menstruate at the age of 13. The duration was from five to six days with a twenty-eight-day interval.

2 Zondek, Bernhard. Gonadotropic Hormone in the Diagnosis of Chorionepithelioma, J. A. M. A. 108:607 (Feb. 20) 1937.

The present illness began with spontaneous vaginal bleeding, which followed two and one-half months of amenorrhea. A few fragments were expelled and discarded by the patient before she was seen. After fifteen hours of active bleeding, the uterus was emptied and a few fragments of thickened decidual tissue were obtained which did not appear abnormal.

The pathologic examination revealed that the specimen consisted grossly of irregular masses of soft tissue which were a brownish white and varied in size from 0.5 to 1 cm in diameter. They were interspersed with a generous amount of freshly coagulated blood. Microscopic examination (figs 1, 2 and 3) showed that the mucosa was markedly hyperplastic and infiltrated throughout with large multinucleated giant cells of a syncytial character. The glands were dilated, deep irregular in shape and lined with secretory epithelium of the lutein phase. The interstitial substance was markedly edematous, showing hemorrhagic extravasation associated with a diffuse infiltration of large wandering cells and broad sheets of Langhans cells. The blood vessels were markedly dilated and surrounded by embryonic cells, which had infiltrated through their walls and hung free in clusters within the lumen.

The general picture was not unlike what one would expect to find in a chorionepithelioma. Owing, however, to the extreme difficulty of making a positive diagnosis of such a

cycle. There was no evidence of a malignant condition. The patient has since made an uneventful convalescence and is now none the worse for her experience.

COMMENT

The case illustrates an exaggerated syncytial reaction which histologically was not unlike that of a chorionepithelioma. The presence of Langhans cells within the lumen of the dilated vessels made the diagnosis all the more apparent. The stormy endometrial reaction was probably due to the combined effect of a low grade infection plus the trauma produced by the long continued use of a metal stem pessary. The manufacture and sale of these appliances should be prohibited. The case also illustrates the importance of the gonadotropic test in the differential diagnosis of uterine scrapings when chorionepithelioma is suspected.

PYLEPHLEBITIS DUE TO PERFORATING
DUODENAL ULCERCHARLES PURCELL ROBERTS, M.D. AND ARTHUR J. HADLER, M.D.
BOSTON

Recently we observed an instance of portal thrombophlebitis and multiple liver abscess following invasion of the vein by a perforating duodenal ulcer. This fistulous sequel is one of many that may result from perforation of a peptic ulcer. The review by Monroe¹ indicates that depending on the location of the lesion in the stomach or proximal intestine any contiguous viscus may be invaded. From the stomach, morbid connection has been found leading to the spleen, transverse colon, duodenum and, through the diaphragm, to the lung, the pericardium and even the heart from the duodenum to the pancreas, pancreatic duct, gallbladder, biliary duct and portal vein. The last eventuality is mentioned in textbooks,² but few actual cases have been reported either in detail or by brief account. It is also more unusual to find reference to pylephlebitis originating in duodenal rather than in gastric ulcer although this distinction is of little importance in the evolution of the sequel. Six³ records of perforating gastric ulcer followed by pylephlebitis are given in the older journals and several⁴ notations without description, of this instance may be found. While reports of four⁵ cases have been discovered—all in the earlier literature—which are similar to the present one in only two⁶ of these is there a suggestion of the direct relation here witnessed, i.e. the separate transfer of infection from the duodenum to the vein without intermediary peritoneal abscess.

When the juxtaposition of the portal vein and the ulcer-bearing area of intestine is considered it is somewhat surprising that the occurrence of portal vein infection is not more frequently encountered.

Fig. 4—Endometrium from second curettage showing a normal quiescent reaction of the preovulatory phase. $\times 100$

condition from microsections alone it was recommended that the patient be treated expectantly until the result of a gonadotropic hormone test was known. The test performed two weeks after the curettage was negative. Expectant treatment was continued for the next two months, after which time the uterus had undergone complete involution and the patient was symptom free.

In view of the previous pathologic changes however a second gonadotropic hormone test was performed with negative results, and also a second curettage, the report of which is as follows. The specimen consisted of a small portion of uterine scrapings which consisted of a few small brownish white pieces of tissue, which were irregular in shape and soft in consistency. The individual portions varied from 3 to 5 mm in diameter. Microscopic examination (fig. 4) showed that the surface and glandular epithelium was regular in outline and quiescent in nature. The interstitial tissue was moderately edematous but showed no cellular infiltration or evidence of activity. The general appearance was that of a normal endometrium in the preovulatory stage of the menstrual

REPORT OF CASE

History—A man, aged 40, a traveling salesman, admitted to the hospital, complained of fever, chills and sweats of six weeks duration. One sister was known to have peptic ulcer proved by roentgenologic study, and another suffered from chronic indigestion.

For fifteen years the patient had noticed hunger pains or epigastric distress about one hour following meals with relief

Fig 1—Appearance of barium filled stomach and duodenum showing clearly the deformity of the duodenal cap. The enlargement of the liver is demonstrated by displacement of the stomach toward the left and inferiorly.

by ingestion of alkaline powders or milk. There had been definite qualitative dyspepsia in that fatty foods repeatedly had caused flatulence. Physicians had given him milk and cream regimens at the times of exacerbation and he had obtained benefit. However no adequate period of treatment had been enforced.

Two months before the onset of his final illness the patient had begun to experience distress again in the upper part of the abdomen. Two weeks later while on a business trip he was seized with a shaking chill followed by fever and sweating which lasted four days. Returning home because of the persistence of this illness, he was seen to become intensely jaundiced toward the end of the next week. The icterus faded slowly from that time. The only notable abdominal pain suffered was at the time of taking cholagogue tablets prescribed by his physician because of developing jaundice when there was sharp discomfort in the right upper quadrant. Shortly before entrance bloating and enlargement of the abdomen appeared. Hospital admission was advised because the patient continued to have a fever of from 101 to 104 F, have chills and sweats of several hours duration and steadily lose both strength and weight.

Examination—The patient was prematurely gray, he looked quite sick and spoke in a whisper. The sclerae showed slight icterus. The skin was pale and sallow, there was evidence of a recent loss of weight. The tongue appeared beefy and dry. The heart showed no abnormality other than persistent tachycardia. Arterial blood pressure measured 130 mm of mercury systolic and 85 mm diastolic. The bases of the lungs posteriorly were relatively dull on percussion. The abdomen was protuberant with bulging flanks, definite fluid wave and shifting dullness, there was very slight tenderness in the right upper quadrant. Liver by ballottement could be felt two fingerbreadths below the right costal margin in the mid-clavicular line, its upper border reached the fifth rib. A splenic nontender edge could just be felt. External hemorrhoids were present.

On admission the value for hemoglobin was 65 per cent (Sahl's method), erythrocytes numbered 3,100,000 and leukocytes 20,000 per cubic millimeter of blood, 74 per cent of the leukocytes were polymorphonuclear neutrophils and 26 per cent were lymphocytes (100 cells counted). The early urine specimens contained no bile but urobilin (two plus on a scale of four). The icteric index of the blood serum was 10 as compared with the normal value of 5. The Wassermann and Hinton reactions of the blood serum were negative. Stool examination by the mercury bichloride test showed bile present in small amount, the guaiac test for occult blood was negative. Microscopic examination revealed no amebae or cysts. Blood culture was negative after seventy-two hours. Blood chemistry studies gave values for nonprotein nitrogen of 24 mg per hundred cubic centimeters, sugar, 85 mg total protein 47 Gm per hundred cubic centimeters, albumin 24 Gm globulin, 23, showing a moderate inversion of the albumin globulin ratio. The Takata-Ara test was negative. Agglutination reactions for typhoid, paratyphoid A and B and undulant fever, and the Weil-Felix reaction for typhus fever were all negative, these being done because of the prolonged pyrexia. Abdominal paracentesis yielded 1500 cc of hazy, straw-colored fluid of specific gravity 1.004 which contained 300 erythrocytes and 1,150 leukocytes per cubic millimeter, 85 per cent of the leukocytes being polymorphonuclear neutrophils. No tumor cells were found in stained sections of the clot. The total protein of this fluid was 0.83 Gm per hundred cubic centimeters, albumin 0.40 Gm, globulin 0.43 Gm and nonprotein nitrogen 18 mg.

X-ray examination of the chest showed the right diaphragm elevated and limited. Gastro-intestinal films and fluoroscopy proved the duodenal cap constantly small and irregular, indicating an ulcer. No evidence of perforation could be seen (fig 1).

Hospital Course—This was hectic, with exhausting chills and sweats and fever, it was early swinging in type then, before death, widely excursive (fig 3). On the last day the patient was found to have a rigid neck and a bilateral positive Kernig sign, but a lumbar puncture drew fluid under low tension with blood cells that proved by postmortem study to be of traumatic origin.

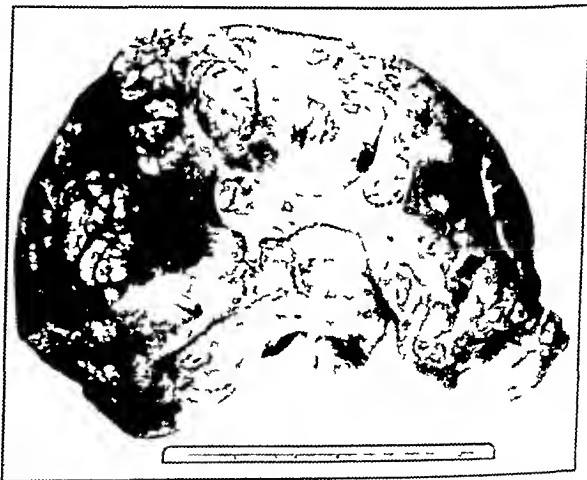

Fig 2—Cut surface of the liver, to indicate arborizing distribution of abscesses in relation to divisions of the portal vein. In the center are seen thrombi within the lumen of a large venous channel.

Before X-ray examination had shown the duodenal location of the ulcer, gastric carcinoma with hepatic metastases was considered with the accompaniment of active infection. The disease process also was suggestive of cholangitis with infectious cirrhosis or more than usual storminess. No doubt remained in the face of jaundice, hepatomegaly, and the high polymorphonuclear percentage of cells in its contents that the locus of sepsis was hepatic, but even after an ulcer had been demonstrated in the intestine no causative relation was assumed.

Necropsy—This revealed a liver containing multiple abscesses (fig 2), the portal vein filled with infected thrombi and suppurative material throughout its hepatic branches. The duodenal ulcer was verified, lying in the posterosuperior wall, and the ulcer bed was found adherent by an inflammatory fibrous tract to the portal vein. It was shown that the ulcer had not perforated into the free peritoneal cavity but had penetrated through scar tissue posteriorly to within from 1 to 2 mm of the lumen of the portal vein. There was no patent sinus tract. Rather, the perforation had resulted in a so called blind fistula with its apex at the venous trunk. Thrombophlebitis was widespread, this being traced downward into the splenic and mesenteric veins. Within the veins the purulent exudate was of a thick, creamy consistency. There were fibrous adhesions between duodenum, gallbladder and transverse colon. The spleen was much enlarged. The gallbladder was distended but contained no calculi. The vermiform appendix showed a bulbous tip but otherwise was normal. The pancreas was intact. The prostate was slightly enlarged. The inferior vena cava exhibited no changes. The heart and its valves showed no pathologic signs. There was moderate passive congestion in the lungs. The brain was swollen, hyperemic and edematous.

COMMENT

The proximity of the duodenum in its first part to major venous channels is pointed out by this consequence. The main portal vein lies intimately on the posterior surface of the intestine, separated only by sheaths of peritoneum, before it ascends in the free border of the gastrohepatic ligament to the liver. While other avenues of perforation are rightly expected in the majority of chronic ulcers, it is not unlikely that the occurrence here detailed should sometimes be observed. Any attempt to avoid this sequel in cases of known ulcer necessarily is dependent on the general measures of ulcer management. The calamity apparently is beyond hope of amelioration once it has occurred and here treatment can be only supportive. Presumptive diagnosis is possible in similar cases, and the concomitance of evident liver sepsis and ulcer history with fluoroscopic demonstration should argue for a direct causal relation.

SUMMARY

A case of pylephlebitis and hepatic suppuration was secondary to perforation of duodenal ulcer, an infrequent but dire complication of this common disease of the intestine.

Skeptical of Authority—The doctors' books are of a different sort from the lawyers' and the preachers. They in their professions depend as yet largely upon authority. The doctor, ever since Galen was toppled from his dominating seat has been skeptical of authority and perhaps too much inclined to novelty. But if he makes any pretense of 'keeping up' with the amazing prodigious and often revolutionizing advances which through some new discovery, occur almost overnight he must read or attend meetings—or better both—Cushing, Harvey, Consecratio Medici and Other Papers. Boston: Little Brown & Co. 1928.

Special Article

THE PHARMACOPEIA AND THE PHYSICIAN

THE USE AND ABUSE OF ERGOT AND PITUITARY

M. EDWARD DAVIS, M.D.

CHICAGO

This is one of a series of articles written by eminent authorities for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopoeial Committee of Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION—ED.

Ergot and solution of posterior pituitary are the most important oxytocic drugs in the pharmacologic armamentarium. Their judicious use has been a boon to the practice of obstetrics. Properly used they are of inestimable value in the course of labor and the puerperium, often contributing directly or indirectly to the saving of human life. However, their indiscriminate use has led to disastrous results for mother and baby. In fact, many authorities have intimated that the undesirable consequences of the improper use of these oxytocic drugs have outweighed the good that they have accomplished. It is because of this serious indictment that the review of the proper indications for the use of these oxytocics in obstetrics may be timely.

ERGOT

Ergot is a fungus that attacks rye and other grains, making them unfit for consumption. The crude drug contains many constituents, but it owes its oxytocic activity largely to the alkaloids which it contains. Many of the pharmacologic investigations of ergot concern themselves with the isolation and study of these alkaloidal constituents. Tanret¹ in 1875 isolated ergotamine, which proved to be inert. Barger and Carr² in 1906 isolated ergotovine, which was found to have oxytocic activity. Stoll³ in 1918 isolated the isomers ergotamine and ergotamine, only the latter alkaloid exhibiting oxytocic properties. Other alkaloids, namely, sensibamine and ergoclavine, have been described. It remained, however, for a group of investigators in 1934 to isolate and describe a new water soluble alkaloid which for the first time satisfactorily accounted for most of the desirable oxytocic activity known to exist in ergot.⁴ The Council on Pharmacy and Chemistry of the American Medical Association has given the name of ergonovine to this new alkaloid.⁵

The chemical and pharmacologic properties of this new substance have been carefully evaluated by a number of investigators, all of whom agree that this new

water soluble, crystalline ergot base, which has the formula $C_{19}H_{23}N_3O_2$, is responsible for most of the oxytocic properties of active ergot preparations⁶

Although this new alkaloid is proving to be highly desirable as a therapeutic agent in obstetrics, the continued investigations on ergot have been productive of a great deal of new information. The extensive researches of Jacobs and Craig⁷ have demonstrated that lysergic acid is the only characteristic fission product common to the four pairs of alkaloids, thus, the final chapter in the chemistry and pharmacology of ergot still remains to be written.

The ergot preparation in the Pharmacopeia of the United States is the fluidextract. When prepared according to official instructions it should contain most of the ergonovine present in the crude drug on which its oxytocic potency depends. The official assay by the U S P cock's comb method will determine this potency. Ergonovine can best be assayed biologically by means of the isolated rabbit's uterus, the official cock's comb method and the isolated rabbit's intestine, and by a colorimetric procedure.⁸ There is considerable variation in the content of this potent alkaloid in the various samples of ergot obtained from one locality and a much greater variation in ergot obtained from different geographic locations.

The present status of ergot therapy has been considerably simplified. The official fluidextract, when properly prepared and stored, provides a good ergot preparation which can be taken by mouth in 30 to 60 minims (2 to 4 cc) doses two or three times daily. It occasionally provokes unpleasant reactions such as nausea and vomiting, in which case its use should be discontinued. Prolonged administration may result in the phenomenon of ergotism, which usually manifests itself in the form of a dry gangrene of the extremities. The drug should therefore not be continued beyond ten days.

The new ergot base ergonovine in the form of a salt may be used orally and parenterally because of its crystalline character. The malleate salt of the base is stable and satisfactory for therapy. For oral administration from 0.2 to 0.4 mg can be given two or three times daily. It has an advantage over the fluidextract preparation in that it can be given intravenously in 0.2 mg doses for its immediate effect when this is desirable. The parenteral routes of administration may be necessary in patients who are under anesthesia or when the oral route is contraindicated. Although as yet no cases of ergotism have been ascribed to ergonovine, prolonged administration of huge doses in experimental animals have resulted in this phenomenon.⁹

The characteristic response of ergot can best be seen in the immediate postpartum period. Some ten or fifteen minutes following the oral administration of the drug, the uterus exhibits increased activity. The normal uterine contractions are increased in rate and severity. The uterine musculature develops considerable tonicity, so that the organ does not completely relax between contractions. This increased muscular tone may persist for as long as an hour, but the rate and intensity of the contractions continue for one or even two hours after the uterine tetany has subsided. The increased rate and

vigor of the contractions and the tetany are both desirable features during the puerperium, for they probably promote a more rapid uterine involution as well as control postpartum bleeding.

Ergonovine does not affect pulse, blood pressure or urinary output. It is therefore particularly indicated in patients who exhibit any of the vascular-renal manifestations of the toxemias of late pregnancy. Fluidextract of ergot contains chemical constituents such as the amines, which may affect blood pressure.

SOLUTION OF POSTERIOR PITUITARY

The oxytocic activity of extracts of the posterior pituitary gland was demonstrated by Dale⁹ in 1906. Blair Bell¹⁰ three years later introduced this most important therapeutic agent in obstetrics. It was not until 1928 that Kamm and his co-workers¹¹ succeeded in separating posterior pituitary into two fractions, one containing the oxytocic principle, pitocin, and the second the diuretic and pressor principle, pitressin.

Solution of posterior pituitary U S P contains both principles and is the most commonly used pituitary preparation in obstetrics. It is standardized as to oxytocic activity. The oxytocic standard is such that each cubic centimeter contains not less than 8 and not more than 12 international units. The international unit, as adopted by the League of Nations, is the amount of oxytocic activity obtained by 0.5 mg of an international standard powder. The pressor principle is so adjusted as to be of the same magnitude as that produced by a comparable solution of a standard pituitary powder.

The pharmacologic action of posterior pituitary is quite uniform. It is entirely inactive when given by mouth. Its intramuscular or subcutaneous administration causes the initiation of uterine motility in from three to five minutes. The uterus contracts vigorously, remaining in this tonic state for several minutes, and, as the tonus diminishes, increasingly vigorous contractions occur. The action of the drug lasts for five or ten minutes and rapidly disappears, to be reinitiated by another dose. The intravenous administration of small doses, 3 minims (0.2 cc), provokes an immediate response. However, the general reaction to this mode of therapy is sometimes quite marked. The patient may develop a marked circumoral pallor, a sense of constriction in the chest, pain in the back of the head, marked palpitation, nausea and occasionally vomiting, simulating shock. The reaction may last several minutes or longer and gradually disappears without any serious effects.

Solution of posterior pituitary has a variable effect on blood pressure of normal persons. Usually they show little or no elevation of blood pressure after therapeutic doses. The pallor which may develop is not an index of a change in blood pressure. However, in patients with hypertension a marked elevation occurs after intravenous or intramuscular administration of the drug. The rise in pressure is transitory and is followed by a return to normal. Solution of posterior pituitary also causes a diminution in the urinary output, which likewise becomes more marked in patients with kidney damage. A temporary anuria may occur in patients with toxemia of pregnancy. These abnormally marked effects of pituitary solutions on blood pressure and urinary output in patients exhibiting toxemia of pregnancy make the use of this drug undesirable in this group.

Dieckmann and Michel¹² noted that parenteral injections of extracts of the posterior lobe of the pituitary were followed by a marked decrease in the volume of urine, an increase in the chloride concentration, and an average rise in the systolic pressure of 51 mm of mercury pressure in a group of patients with pre-eclamptic toxemia studied during pregnancy. Less marked changes were noted in normal gestation. In addition to warning of the inadvisability of using solution of posterior pituitary as an oxytocic drug in patients exhibiting evidences of toxemia, these authors suggest that the changes induced by the drug may be of some diagnostic and prognostic value in the management of these cases.

INDICATIONS FOR OXYTIC DRUGS

Nonpregnant Patients—Although solution of posterior pituitary will cause some contractions and tonicity of the uterus of the nonpregnant person, it is rarely indicated. The pathologic cause for the bleeding should be determined and treated. Any increased bleeding at the time of the menstrual periods or bleeding occurring between periods is sufficiently serious to warrant a careful examination and a correct diagnosis. It is never justifiable to give ergot or pituitary extract as a temporary expedient in the hope that this will control the bleeding unless one is absolutely certain that the underlying pathologic process causing the abnormal bleeding can await treatment.

Therapeutic Abortion—Oxytocic drugs will not terminate a normal gestation in the first trimester of pregnancy. The uterus is not responsive to ergot and pituitary during this period. Experimental evidence would indicate that the corpus luteum of pregnancy inhibits uterine response to posterior pituitary extracts. As term approaches the uterus becomes more and more susceptible to the action of this substance. Near term one can cause the uterus to contract vigorously after the administration of the drug.

Although oxytocic drugs fail to initiate an abortion in a normal pregnancy, ergot and pituitary may be used to hasten or to complete the process once it has begun. In inevitable and incomplete abortions, solution of posterior pituitary can be used in 0.5 to 1 cc doses intramuscularly with benefit to the patient. This will cause increased uterine motility which may result in a complete and rapid termination of the process or the evacuation of portions of the products of conception still in the uterus. Profuse bleeding should be controlled by curettage and packing if necessary. Following the completion of an abortion, ergot can be given orally for several days to limit the bleeding and favor normal involution.

Induction of Labor—The medicinal induction of labor is rarely successful until term is approached. This is probably due to a lack of sensitivity on the part of the uterine musculature to oxytocic stimuli. If, therefore, it is necessary to induce labor for some complication prior to term, one usually has to resort to mechanical means. The method of medicinal induction of labor at or near term at the Chicago Lying-in Hospital consists of the following procedure: Castor oil, 1½ ounces (42 cc), is given early in the morning, followed two hours later by quinine in 3 grain (0.2 Gm) doses at hourly or half hourly intervals for four or five doses, followed by graduated doses of solution of posterior pituitary, beginning with half a minim (0.03 cc) and increasing half a minim at each dose fifteen minutes apart until

3 minims (0.02 cc) is given. The latter dose can be repeated until a total of 1 cc is used. The uterus should be carefully observed, and if it exhibits tetanic contractions so that the fetal heart tones are interfered with, solution of posterior pituitary is discontinued. In the rare event that the continued tonic state of the uterus so seriously interferes with the uteroplacental circulation that the fetal heart rate is dangerously slowed, it may be necessary to administer ether to the patient for several minutes to relax the uterus. The administration of the drug is stopped when regular rhythmic contractions are initiated in the course of the induction.

Labor—The oxytocic drugs are almost never indicated during the first and second stages of labor. It is dangerous to interfere with the normal uterine motility. Solution of posterior pituitary given during the course of labor initiates a marked tetany of the uterus. As this tone diminishes, the uterine contractions increase in severity and frequency. This abnormal uterine action may result in an interference with the placental circulation resulting in fetal asphyxia and even death. It may likewise result in an interference with the uterine circulation and subsequent damage to the uterine musculature. The force of the uterine contractions during the presenting part against an incompletely prepared passageway may result in serious lacerations of the cervix, the vagina or perineum or, in the event that the resistance offered by these structures is too great, the uterus may rupture. Furthermore, the abnormal stimulus provided by the solution of posterior pituitary may completely alter the normal course of labor so that serious operative interventions may be necessitated in an attempt to save a baby in jeopardy or to conclude an abnormal labor.

Occasionally uterine inertia develops as a result of a lack of tone on the part of the uterine musculature or because of the general physical condition of the patient. Oxytocic drugs are rarely indicated in stimulating uterine contractions. The underlying condition that is responsible for the inertia should receive proper treatment. Thus, physical exhaustion on the part of the patient from a long, arduous labor may be best treated by sedatives. A period of complete rest will often result in a recurrence of normal uterine activity and a rapid completion of the labor. In some cases rupture of the membranes under proper conditions provides a satisfactory stimulus to poor and ineffective pains. At other times a hot enema may do the same thing. Rarely is it advisable to give solution of posterior pituitary. If this is done, the dosage should be limited to 1 or 2 minims subcutaneously. This should not be repeated many times. If there is any tendency to uterine tetany or to abnormal uterine motility, or if the fetal heart rate or rhythm is disturbed, the drug should be immediately discontinued and the uterus calmed with a narcotic.

Solution of posterior pituitary and ergot find their greatest usefulness in the third stage of labor. Used judiciously and with the proper indications the oxytocic drugs may often prevent the occurrence of postpartum hemorrhage and the serious results that may be caused by it.

In the normal conduct of the third stage of labor it is usually advisable to await the complete separation of the placenta, after which its expulsion can be aided. Immediately after the birth of the placenta, 1 cc of solution of posterior pituitary can be given intramuscularly. In the event that the patient has had no anesthetic, fluid extract of ergot can be given by mouth or ergonovine can be given parenterally. These oxytocics

¹² Dieckmann W. J. and Michel H. L. Am J Obst & Gynec 33: 131 (Jan) 1937

should help maintain the uterus in a contracted state, avoiding any unnecessary bleeding.

If excessive bleeding occurs after the delivery of the baby and prior to the placental separation, one should administer 1 cc of solution of posterior pituitary intramuscularly. The placenta can then be expressed by Crede's method. If this procedure fails to separate and expel the placenta, one should consider its manual removal in the face of continued hemorrhage.

Should excessive bleeding occur after the expulsion of the placenta, one must determine the cause for the bleeding. Uterine atony is only one of the causes for postpartum hemorrhages. Pastore¹³ recently reported that it accounted for only 22 per cent of the hemorrhages occurring in his series of cases. Portions of the placenta may be retained in the uterus, resulting in a failure of the uterus to remain contracted. These fragments must be manually removed under proper aseptic conditions, after which oxytocic drugs will usually control further bleeding. Trauma of the soft parts, such as deep cervical tears and uterine rupture, may lead to serious and even fatal postpartum hemorrhage, which, needless to say, no oxytocic drugs will control. A careful diagnosis must always be made before the indiscriminate use of drugs is resorted to. When the hemorrhage is the result of uterine atony, solution of posterior pituitary in 1 cc doses should be given subcutaneously or intramuscularly. Small doses, from 2 to 3 minims, can be administered intravenously in an emergency regardless of the possible reaction. Pastore reports five cases of pituitary reactions in his series of ninety-six postpartum hemorrhages, with one fatal case possibly due to the use of pituitary. Ergonovine is the ideal drug because of the rapidity of its action and the sustaining character of the effect. It can be given in 0.2 mg doses intravenously. If the patient is awake, fluid extract of ergot can be given by mouth.

Postpartum hemorrhage accounts for 10 to 12 per cent of the maternal deaths that occur every year. It is therefore a serious contributing factor to the high maternal mortality. It is a complication that is ever before the mind of the obstetric attendant. The rapidity of its onset, its magnitude and the rapid development of the serious symptoms often overwhelm the accoucheur. The careful and orderly management of this complication and the proper use of oxytocic drugs will usually result in a favorable outcome.

PUERPERIUM

The use of oxytocic drugs in the puerperium has enjoyed almost universal popularity. Ergot has been the therapeutic bulwark for this period. It has been credited with hastening normal involution, decreasing the likelihood of late postpartum bleeding, limiting the probable spread of intra-uterine infection if present, and helping to maintain the genital organs in the best state possible.

Normal uterine involution is the physiologic process by which the puerperal uterus is rapidly reduced to about one-twentieth its size and returned to the normal nonpregnant state. Many factors may influence this important function and result in a large, boggy uterus. This subinvolution of the uterus predisposes to infection, to late postpartum bleeding and to subsequent malpositions. Davis, Adair and Pearl¹⁴ demonstrated the fact that improper lochial drainage as a result of

lack of muscular tone often contributes to a retardation of normal involution. Oxytocic drugs stimulate uterine contractions and tone, thereby favoring a more rapid involution.

Infection of the uterus or its appendages seriously delays involution. The relaxed uterus favors the retention of infected clots in its cavity and a spread of this infection in the genital organs and to environmental structures. A lack of uterine tone may result in an extension of infected thrombi from the vessels in the placental site. Theory and practice favor the maintenance of the uterus in a state of tone by the use of oxytocic drugs.

It has been the accepted practice at the Chicago Lying-in Hospital to prescribe ergot in the puerperium for delayed involution. Fluid extract of ergot, from 30 to 60 minims three times daily, or ergonovine maleate, from 0.2 to 0.4 mg three times daily, can be given to patients who have had a postpartum hemorrhage, a difficult forceps delivery, intra-uterine manipulation, abnormal lochia, fever regardless of the cause, or delayed involution without cause. This therapy is kept up for at least three days or as long as is necessary, this medication should be rarely continued beyond a week or ten days, however, because of the danger of ergotism. If uterine contractions become too painful, the dose of the drug is reduced or entirely omitted. The prophylactic use of ergot to assure a normal involution is probably of some value, although further studies will be necessary to confirm this impression.

THE ABUSE OF PITUITARY

Posterior pituitary preparations have been woefully misused in the conduct of obstetric cases. It has been given indiscriminately in the first and second stages of labor to increase the intensity of uterine action and to speed up the normal processes. Normally, uterine motility is a well regulated, physiologic action resulting in steady, even, though at times slow, progress of labor. However, this progress is accomplished with a minimum of danger to the birth passageway and the passenger. During the first stage the uterine contractions progressively increase in frequency, duration and intensity. However normally this uterine activity skilfully produces effacement and dilatation of the cervix. The uterus, like all muscular organs, relaxes between contractions to allow for recovery of its musculature and for the proper continuation of an adequate placental circulation. The second stage, during which the baby is gradually pushed through the birth canal is likewise orderly. Now the baby's head or presenting part is carefully driven against a resisting pelvic floor which must be slowly stretched to allow for the ultimate passage of the baby.

Solution of posterior pituitary upsets this carefully synchronized mechanism of labor. Violent uterine contractions initiated by oxytocics drive the baby's head against a partially effaced and dilated cervix. Soft tissues are battered, bruised or torn. The intensity of the contractions often results in deep cervical lacerations or, when the resistance offered by these structures is too great, in ruptures of the contractile and isthmic portions of the uterus. The tetany of the uterus interferes with the placental circulation, and asphyxia or death of the baby is the inevitable consequence. In the second stage the violent uterine contractions initiated by pituitary may result in extensive, irreparable damage to the soft tissues and the pelvic floor in brain hemorrhage in the baby. Babies are literally driven through unprepared passageways at a terrific cost to them and to their

¹³ Pastore, J. B. *Am. J. Obst. & Gynec.* 32: 280 (Aug.) 1936.

mothers De Lee¹⁵ says he feels certain that the indiscriminate use of pituitary preparations is one of the four major causes responsible for the persistently high material and fetal death rates in the United States

Recent years have seen the introduction of a number of oxytocic preparations in which posterior pituitary is combined with some form of thymus gland extract. This combination was heralded as the ideal oxytocic for labor, resulting in an increase in the effectiveness of the uterine contractions without the inherent tonicity and unbridled activity. Thus, they are supposed to speed up labor along its normal physiologic course. This utopian pharmacologic action so far has proved to be nonexistent, for these preparations represent pituitary solutions diluted with inactive thymus gland substance, retaining all the undesirable and dangerous action of pituitary. It can thus be concluded that the physician who wishes to serve womankind conscientiously and honestly must allow labor to take its normal course, rarely resorting to expedients which might hasten the process but which inevitably carry in their wake injury, mild or serious, and even death to mother and baby

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

HOWARD A CARTER Secretary

CROSLY XERVAC NOT ACCEPTABLE

Manufacturer The Crosley Radio Corporation, Cincinnati

In the words of the manufacturer, "The Crosley Xervac is an apparatus designed to stimulate and aid the growth of hair and develop a healthy scalp condition by increasing the efficiency of the circulation of blood in the deep tissues of the scalp." Thus, the firm claims, is accomplished through the application of alternate positive and negative pressures by means of compressor and vacuum pump attached to a helmet and regulated by controls to suit the individual case. It operates on either direct or alternating current. The underlying theory is that the change in pressures will act as a pump filling and emptying the vascular network in the scalp so that increased circulation will result in nourishment of tissue and regrowth of hair. This theory, in the opinion of the firm, has been substantiated clinically by its consultant who investigated and reported¹ on the unit.

The Council on Physical Therapy investigated the apparatus and stated, in a preliminary report (THE JOURNAL, May 1, 1937, p 1505), that insufficient evidence had been presented to warrant inclusion of the unit in its list of accepted devices.

Continuing its investigation, the Council studied twenty-seven cases treated with the Xervac. The procedure consisted of half-hour sittings, three times a week. Difficulty was experienced in obtaining a larger number of patients, particularly those with different types of alopecia, who were willing or able to take treatments over a long period of time. A number of patients were seen only once or twice monthly, since they found it more convenient to be treated at barber shops or beauty parlors.

While there is no agreement on classification for alopecia, the following common types of baldness seen by dermatologists are mentioned in this report:

- 1 Alopecia seborrhoica (definite seborrhea of the scalp)
- 2 Alopecia systemica (loss of hair seemingly caused by a systemic disturbance, no evidence of a local disease)
- 3 Alopecia prematura (simply premature loss of hair)
- 4 Alopecia areata
- 5 Alopecia hereditaria (family history of early baldness, no evidence of scalp disease)
- 6 Mixed types
- 7 Alopecia idiopathica (cause unknown)

15 De Lee J B and Greenhill J P. The 1936 Year Book of Obstetrics and Gynecology. Chicago Year Book Publishers, Inc. 1936
1 Cuetio A A. Journal Lancet 59 571 (Nov.) 1936

Common baldness usually consists of the idiopathic, hereditary or seborrheic types or a combination of two or three types. An outline of the cases investigated by the Council is given in the accompanying table.

A summary of the figures reveals three cases in which there was diminution of falling hair and new hair was growing, and two cases of increase of lanugo hair. In sixteen cases the results were negative, while in the six remaining cases the results were unknown since no follow-up data could be obtained. In five cases, less than one hour of treatment was given.

All these cases were compared with a similar series in which other methods had been employed. In the opinion of the Council, results were less pronounced in the cases treated by the Xervac than those achieved in the other series, in which topical remedies or conventional methods, such as massage and electric vibration, were employed.

Report of Xervac Treatments

Patient's Number	Age	Hours of Treatment	Diagnosis Type of Alopecia	Results
1	24	12	Seborrhoica	Negative
2	19	4	Seborrhoica	Negative
3	60	8½	Seborrhoica	Negative
11	36	6	Seborrhoica	Negative
17	40	2	Seborrhoica	Unknown
23	63	¾	Seborrhoica	Unknown
6	34	10½	Systemica	Hair falling less, new hair growing
9	38	4	Systemica	Negative
10	30	4	Systemica	Negative
12	26	¾	Systemica	Unknown
18	42	0½	Systemica	Hair falling less, new hair growing
24	48	6	Prematura	Negative
26	30	2	Prematura	Negative
13	24	17	Prematura (probably hereditaria)	Some increase of lanugo hair
21	24	9½	Prematura (probably hereditaria)	Negative
4	50	5½	Prematura (seborrhoica et hereditaria)	Negative
8	24	3	Prematura (hereditaria or idiopathica)	Negative
7	29	12½	Areata	New hair growing, hair has stopped falling
15	40	½	Areata	Unknown
25	36	½	Areata	Unknown
19	30	10½	Areata (universal)	Negative
14	27	0	Hereditaria	Negative
16	30	15	Hereditaria	Negative
20	24	20½	Mixed (probably part systemic and part hereditary)	Definite increase of lanugo hair
3	29	26	X-ray alopecia	Negative
22	60	1	Senilis	Unknown
27	27	4	Idiopathica	Negative

Results have not been encouraging compared to the amount of time and effort spent in acquiring them. The only result seen in common baldness is an increase in lanugo hair (down) in a very few men who have taken regular treatment over a period of three or four months. Whether or not this lanugo hair will change to real hair as a result of continued treatment will not be known for many months. In most instances the results were negative.

The prognosis is promising in the systemic type caused by febrile or other temporary diseases, and less favorable when the condition is due to long continued systemic disturbances. Therefore, the few favorable results reported mean little. The same is true for alopecia areata. In this type the hair may never return, on the other hand it may return spontaneously at any time.

Apparently the method in itself is not harmful, but that cannot be regarded as a recommendation. An objection to the use of the Xervac arises from the possibility that in some barber shops and beauty parlors carelessness in the matter of sanitation may cause the spread of disease.

In the opinion of the Council the results of the present investigation fail to support the claims of the manufacturer. The Council on Physical Therapy voted not to include the Crosley Xervac in its list of accepted devices.

THE COUNCIL ON FOODS HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

FRANKLIN C BING, Secretary

THE APPLE IN THE MANAGEMENT OF DIARRHEA IN CHILDREN

The use of fresh apples in the dietary treatment of diarrhea in infants and small children has been much publicized within recent years. Latterly, preparations of dried and powdered apple have been similarly acclaimed. The Council realizes that a final evaluation of the usefulness of the apple, fresh or dried, can be obtained only after considerable clinical experience. The present review provides a brief survey of the evidence available at the present time.

HISTORY

The use of scraped raw apples as a home remedy for diarrhea can be traced back for many years in Germany and other European countries. Shachter¹ refers to an English book published in 1775 which describes the use of the fruit treatment (apples preferred) in dysentery. Heisler² reported in 1928 that the apple diet had been used in the Children's Clinic at Konigsfeld for twenty years or more and before that had been a familiar household remedy in the Schwartzwald. Moro³ of Heidelberg is usually credited with standardizing and introducing the apple diet to the medical profession. The use of apples in the treatment of diarrhea was first reported in the American literature by Birnberg⁴ in 1933.

CLINICAL RESULTS WITH RAW APPLES

The available clinical reports cover practically every kind of diarrhea that is encountered in pediatric practice.⁵ Most of the reports are favorable, not to say enthusiastic, although some are relatively uncritical and difficult to evaluate. Opinions vary considerably as to the efficacy of the apple diet in specific infectious diarrheas such as are encountered with the dysentery group of organisms. However, many authors have found that regardless of the cause or seriousness of the condition the apple diet is one of the most successful measures now available for terminating both acute and chronic diarrheas. Moro³ in his early report stated that, of fifty-two patients treated, twenty-two cases were diagnosed as acute dysentery, fifteen as dysentery, eight as celiac disease, five as mucous colitis, one as chronic dysentery and one as typhus fever. The most unfavorable report yet published is that of Smith and Fried,⁶

who have found that in their hands the apple diet is not more effective than other standard dietary procedures, for example, the use of so-called protein milk.

DIETARY PROCEDURE

The apple is used in varying amounts according to the age of the child and the requirements of the individual patient. Moro³ believes that only mellow ripe apples should be used, whereas Heisler² states that the immature sour apple is equally effective. All agree that the apple should be cored and the seeds removed, but opinions vary as to whether the apple should be peeled or unpeeled. For older children (1 year or older) from 1 to 4 tablespoonfuls of the pulp are fed every hour or every two hours for from twenty-four to forty-eight hours, or from 500 to 1,500 Gm daily. This is said to be equivalent to from seven to twenty medium sized apples.³ The caloric value of the fresh apple has been estimated⁵ as about 60 calories per hundred grams. Most reports indicate that although the scraped apple furnishes a fairly large amount of fluid it is not enough for the child's needs and water or weak tea is offered in addition. For children who are dehydrated, the parenteral administration of fluids may also be necessary. Either the tea or the apples may be sweetened by the addition of saccharin, or the apples may be sweetened with a small amount of ripe banana pulp. Tompkins⁵ reports that if the apple is not readily taken a carbohydrate preparation rich in dextrins can be sprinkled over it. After the first formed stool has appeared (usually in from twenty-four to seventy-two hours) the older children are placed on a carefully chosen transition diet consisting largely of cereal broths, zwieback or dry toast, meat broth, scraped beef and cottage cheese. Milk, vegetables and fruits are added gradually after about two days on the transition diet. A transition diet suitable for use in infancy is discussed later in the present report in connection with dried apple powder.

THE PHYSIOLOGIC BASIS FOR THE APPLE REGIMEN

Various theories⁸ have been advanced ascribing the success of this diet to some component of the apple. It has been suggested that the astringent action of the tannic acid compounds which are present in small amounts in the apple aids in protecting the mucous membrane of the gastro intestinal tract, but there is little direct evidence in favor of this view. Other investigators have attributed the beneficial effects of the apple to the malic and other fruit acids present. In support of this theory is the observation that certain fruit juices such as lemon and current juice have been observed to produce effects somewhat similar to those obtained with scraped apple. But apple sauce which has been rendered alkaline by the addition of sodium hydroxide has been shown to be as effective as the untreated fruit, an observation which is a serious obstacle in the way of the acceptance of the acid theory. Perhaps the hypothesis which is most frequently advanced is that the effectiveness of the apple may be attributed chiefly to pectin. This theory is supported by the observation that pectin alone or preparations of pectin and agar are reported to be practically as efficacious as raw apple pulp.⁹ Pectin has been assumed to exert its effect by removal of toxic substances because of its colloidal properties and its buffering action, and also because it may serve as a source of galacturonic acid in the intestine. There is evidence that rabbits fed pectin can handle more readily a toxic substance such as menthol, which is detoxicated by coupling with glycuronic acid and excreted in the urine.¹⁰ Much more evidence will be needed, however, before the precise mechanisms involved are made clear.

DRIED APPLE POWDER

Dried apple powder prepared under the sponsorship of the Munich Children's Clinic has been used in Europe since 1931.

and is reported to produce results similar to those obtained with scraped raw apple pulp¹¹ The apple powder is in fact considered by some clinicians superior to the scraped apple pulp for children under 1 year of age The powdered apple must be kept in a tight container to prevent absorption of moisture The powder is usually given (in from 4 to 10 per cent solutions) in amounts varying from a total of 24 to 36 Gm for babies under 1 year, or from 80 to 100 Gm for older children The apple powder is sometimes dissolved in boiled water or weak tea but may also be given in diluted skimmed milk Leffkowitz¹² recommends for mild cases in young infants a mixture consisting of equal parts of skimmed milk and water in which 5 per cent of apple powder is dissolved Sugar is omitted for the first two or three days and the mixture given in the volume to which the infant is accustomed Thus the infant usually receives from 30 to 45 Gm of apple powder daily, which Leffkowitz considers the maximum amount advisable On the second or third day 5 per cent of a dextrin-maltose preparation is incorporated After the fourth or fifth day the apple powder is gradually decreased and the concentration of milk and sugar increased until the infant is eventually returned to his normal feeding mixture In severe and chronic cases Leffkowitz administers a 2 to 5 per cent solution of apple powder in weak tea for the first six to twelve hours, and the return to the normal diet after normal stools have appeared is even more gradual than in the milder cases

SUMMARY

The evidence which is now available indicates that the apple is useful as a therapeutic agent in the dietary management of diarrhea The mechanism responsible for the reported success of this diet is not clear

Apple powder when suitably prepared is a wholesome food and offers a convenient preparation for use in the management of diarrhea of infancy and childhood It should be emphasized, however, that the use of the fresh or dried apple does not obviate the necessity for other measures, including parenteral administration of fluids when indicated, the careful selection of a suitable transition diet, and competent pediatric supervision

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED

FRANKLIN C BING Secretary

APPELLA APPLE POWDER

Manufacturer—The Appella Corporation, Yakima, Wash

Description—Powdered dried apple pulp A blend of powder produced from several varieties of apples selected for their high content of pectin and uronic acids

Manufacture—Selected apples, high in pectin and uronic acids, are thoroughly washed, cored, peeled and dried to a definite moisture content The partially dried apples are spray washed, flaked, treated with superheated steam to destroy micro organisms, vacuum dried, powdered, automatically packed and sealed in air tight containers To maintain color the apples are lightly treated with sulfur dioxide during the preliminary drying process The sulfur dioxide is largely removed in the final drying process The fruit is powdered in an air conditioned room with humidity ranging from 14 to 25 per cent Two per cent tricalcium phosphate is added to prevent caking

Analysis (submitted by manufacturer)—Moisture 20%, total solids 98.0%, ash 1.8%, fat (ether extract) 2.5%, protein (N \times 6.25) 1.5%, crude fiber 6.7%, reducing sugars before inversion 52.0%, sucrose [(total reducing sugars after inversion minus reducing sugars) \times 0.95] 17.1%, pectin (alcohol precipitate) 5.2%, uronic acids 9.2%, total carbohydrates other than

crude fiber (by difference) 84.1%, tannin and coloring matter 1.4%, total sulfurous acid 0.01%, total acidity (as malic acid) 2.9%, pH 3.5 Alkalinity of ash, equivalent to 240 cc of 0.1 N acid/100 Gm powder Sodium (Na) 0.11%, potassium (K) 0.87%, calcium (Ca) 0.015%, magnesium (Mg) 0.029%, copper (Cu) 0.0008%, iron (Fe) 0.0125%, phosphorus (P) 0.0014%, chloride 0.216%, total sulfur (S) 0.137%, silica (SiO₂) 0.01%, sulfur dioxide 0.0004%

Calories—37 per gram, 95 per ounce

Claims of Manufacturer—A wholesome food product, especially useful in the dietary management of diarrhea

LIFESTAFF NATURAL GRAIN PORRIDGE, WHEAT AND RYE

LIFESTAFF NATURAL GRAIN MEAL, WHEAT AND RYE

Manufacturer—Lifestaff Natural Food Company, St Louis

Description—Ground whole wheat and rye seed grains

Manufacture—Whole soft wheat and rye seed grains are sorted, sifted, mechanically cleaned and scoured Grains light in weight are discarded Specified amounts are mixed by hand, coarsely ground and sifted The coarse particles are ground again and mixed with small particles The product of coarse grinds is called "Porridge," whereas "Meal" is obtained by successive fine grinds Each product is bagged, weighed, closed and labeled

Analysis (submitted by manufacturer)—Moisture 8.8%, total solids 91.2%, ash 1.8%, fat (ether extract) 1.8%, protein (N \times 6.25) 12.5%, reducing sugars as invert sugar 2.9%, reducing sugars as dextrose 0.2%, crude fiber 1.7%, carbohydrates other than crude fiber (by difference) 73.4%

Calories—36 per gram, 102 per ounce

DUNN'S DIAMOND "D" BRAND GELATINS SUPER, AA, A, 1 EXTRA AND 1 GRADES

Manufacturer—Thomas W Dunn Company, New York

Description—Granular plain gelatins of different jelly strengths

Manufacture—Ossein, dry and green calf skin pieces and trimmings are soaked in milk of lime solution for from four to eight weeks, washed and steam cooked Runs taken off at different degrees of temperature, varying in jelly strength, are mixed, concentrated, filtered and jelled The sheets are stove dried, ground and packed Imported goods are passed by the U S Department of Agriculture at port of entry and must conform to Pure Food Standards Various makes are blended to produce the standard grades

Analysis (submitted by manufacturer)—(Range of analyses for all grades) Moisture 11.0 to 14.0%, ash 0.3 to 2.0%, fat none, protein (N \times 5.55) 8.30 to 87.0%, carbohydrates none, jelly strength of different grades 130 to 260

Parts per million Arsenic (As) 0.2 to 1.0, copper (Cu) less than 15.0, zinc (Zn) 0.0 to 20.0, lead (Pb) none, SO₂ none added

Calories—3.3 to 3.5 per gram, 9.4 to 9.9 per ounce

FOULDS MACARONI, ELBOW MACARONI FOULDS SPAGHETTI, ELBOW SPAGHETTI

Manufacturer—Foulds Milling Company, Libertyville, Ill

Description—Macaroni and spaghetti prepared from durum wheat semolina, water and salt

Manufacture—Durum wheat semolina, salted, is kneaded with water under corrugated steel rolls, forced through dies containing holes of appropriate diameter and shape to form the various types of macaroni and spaghetti, dried and packaged

Analysis (submitted by manufacturer)—Moisture 10.1%, total solids 89.9%, ash (other than NaCl) 0.6%, sodium chloride (NaCl) 1.0%, fat (ether extract) 1.8%, protein (N \times 5.7) 12.6%, crude fiber 0.2%, carbohydrates (by difference) 73.7%

Calories—36 per gram, 102 per ounce

MINERALS AND INTESTINAL FLORA

The gastro-intestinal tract is not sterile, implantation probably takes place soon after birth. Under ordinary conditions there is such an enormous number of non-pathogenic bacteria in the intestine that it has been estimated that from one fourth to one third of the dry matter of the feces consists of bacteria. In herbivora such saprophytes are of great significance in the utilization of food, and the bacterial protein itself may under certain circumstances provide available nitrogen for the nutrition of the host. In man, under usual dietary conditions, the predominating organism present is the colon bacillus, which is known to bring about characteristic changes in unabsorbed residues of the digestion of protein as well as of the proteins of the intestinal secretions. It has long been known that toxic amines and also phenols are thus produced. Another type of organism, present in relatively small numbers, is the aciduric group. These bacteria act on various carbohydrates to produce lactic acid. Thus lactose and dextrin favor the predominance of the aciduric flora, the metabolism of which produces a medium unfavorable to the coli forms. The nature of the diet is therefore important in influencing the character of the intestinal flora.

A recent study by Eppright, Valley and Smith¹ emphasizes another factor in the control of the bacteria of the intestine. Their experiments were carried out on albino rats—animals with intestinal flora closely resembling that of man. A basal ration extremely poor in inorganic salts but containing a large proportion of dextrin was variously modified with a nutritionally complete salt mixture and with simple combinations of inorganic elements. With the low salt diet the fecal aciduric organisms in these animals practically disappeared within two weeks after the beginning of administration and were replaced by colon bacilli and enterococci. The complete salt mixture brought about a marked preponderance of aciduric organisms and concomitant loss of the "putrefactive" type. Acidophilus

could not be maintained in high concentration when sodium, potassium and chlorine, calcium alone or phosphorus alone were added to the basal salt-poor ration. On the other hand, calcium and phosphorus together in the diet produced a marked predominance of aciduric organisms and an accompanying decrease of the coli and enterococcus types. These studies leave little doubt that, when the other part of the diet is favorable, the presence of calcium and phosphorus is essential to the vigorous growth of the typical aciduric organisms of the intestine.

These observations are of further interest in connection with the growth of the host animals under the experimental conditions. It has been shown² that increase in body weight of the host animals occurred only when calcium and phosphorus were added to the salt-deficient basal diet either as a complete salt mixture or in simpler combinations. The conclusion seems obvious that the material in the intestine which represents the end products of digestion of the ration, and which is absorbed by the host on the one hand and becomes a medium for the nutrition of the intestinal bacteria on the other, will not suffice for either purpose if calcium and phosphorus in suitable amounts are absent. These observations reemphasize the necessity for calcium and phosphorus in the metabolism of living cells.

HEADED FOR THE LAST CENSUS?

Ever since the famous attempt by Malthus to prophesy the extent of future populations, numerous other opinions have been advanced on the subject. The complete failure of his early prediction to materialize is reflected in most of the recent studies, which deal with the question of probable underpopulation rather than the malthusian forecast of unrestricted increase. The true interpretation of population trends, however, has been somewhat concealed by the fact that in most countries the birth rate per thousand still exceeds by a moderate margin the death rate. As has been pointed out by a number of authorities, this increase in population is an illusion as far as its ultimate significance is concerned. The direct comparison between the birth rate and the death rate is a crude method and fails to take into account certain other factors the recognition of which necessitates an utterly different conclusion. The disparity is due partly to the exceptionally low death rate in most countries, which in its turn is largely the result of the extraordinary improvements in measures of preventive medicine and the more than "normal" proportion of young and early middle aged persons in the total population.

In a recent book³ discussing this subject as far as it concerns the British commonwealth of nations, it was pointed out that population may be affected by four

¹ Eppright, E. S., Valley, G. and Smith, A. H. *J. Biol. Chem.* 34: 51 (July) 1937.

² Eppright, E. S. and Smith, A. H. *J. Biol. Chem.* 34: 51 (July) 1937.
³ McCleary, G. F. *The Menace of Irish Dependence*. George Allen & Unwin Ltd. 1937.

principal factors fertility rates, mortality rates, and variations in immigration and emigration. For the purposes of considering population trends, however, the first two factors are the more important. As evidence of change in the first factor, McCleary cites the birth rate for England and Wales from 1841 to 1935. In the period from 1841 to 1850 the annual number of births per thousand of population was 32.6, this rose to 35.4 in the period from 1871 to 1880 but has since fallen with almost consistent regularity to 14.7 in 1935. This fall in birth rate has been accompanied by a fall in death rate, so that although the birth rate in 1935 was 14.7 the death rate had also fallen to 12.3, still leaving a favorable crude balance. Both rates, however, depend on the age constitution of the population and the proportion of females. The significance of such factors can be assigned by computing the expectation of life at different ages as derived from life tables. When this method is followed, the true death rate for England and Wales becomes 16.45 per thousand—well above the crude birth rate. But even this is not accurate, since the crude birth rate is higher than the true birth rate when the latter is computed on the percentage of women at child-bearing ages in the general population. The first step in the calculation of a true fertility rate is to determine the number of children borne annually by a thousand women from 15 to 16 years of age—the first year of the child-bearing period. A similar rate is then worked out for each of the other years of the child-bearing period, the total of which, divided by 1,000, gives the number of children that would, on the average, be borne by one woman living to the age of 50. Taking the rate at which children are being born at a given time and place, the gross reproduction rate is calculated by the number of girl babies that will on the average be borne by every woman who lives through the child-bearing period. If this rate is less than one, clearly the population must diminish. When calculated for England and Wales, the gross reproduction rate has been below unity since 1926, in 1933 it was 0.845.

Another method of calculation has been described by Lorimer, Osborne and Carr-Saunders and cited by Burch.² If the total number of individuals in a stationary population are listed in five year age groups, each group is larger than the next older one and smaller than the next younger. This relationship has now changed for England and even for the United States in recent years, where there are more children from 5 to 9 years of age than there are from 0 to 4. This fact indicates an inability of the younger group to replace the older one, a course which if continued for a relatively short time, would obviously cause a decrease in the total population. Trends apparently similar to those in England and the United States have

been noted in almost all other countries, although in some of them the process is not as far advanced. In some, indeed, the trend is still so slightly evident that its actuality has been debated.³ Many important questions hang on the continuation of the trends now evident.

Dr Enid Charles, according to McCleary, has estimated the population of England and Wales from 1935 to 2035 on three different assumptions, all of which, however, agree in taking no account of immigration and emigration. The first estimate assumes that fertility and mortality for each year and age will remain constant at the 1933 level. On this assumption the population, which at the 1931 census was about 40,000,000, would rise to a maximum of roughly 41,000,000 in 1943 and fall to 36,000,000 by 1975 and to approximately 20,000,000 by 2035. The second estimate assumes that fertility and mortality would continue to fall as suggested by the experience of recent years. On the specific assumptions modifying this prophecy, the population would reach a maximum of 40,600,000 in 1940 and fall to 31,400,000 by 1975 and to 4,426,000 by 2035. In the third estimate it is assumed that mortality would continue to fall but that fertility would rise to the level of 1931 (about 10 per cent higher than 1933) and then remain constant. On these assumptions the population would reach nearly 44,000,000 in 1960 and decline to 43,000,000 in 1975 and to 33,600,000 by 2035. Similar figures, ignoring possible immigration or emigration, have been calculated for the United States, with the probably conservative estimate that our population should increase by about 25,000,000 during the next forty years.

Various conjectures have been suggested to explain these amazing changes in population trends. In some places the decline in the birth rate began at a time when the practice of contraception had received an enormous stimulus, but because of similar declines in countries in which contraception receives little application this view has not been generally accepted. According to Thomas,⁴ some would explain the phenomenon as the working of a natural law, fertility being an increment of the size or density of population, and the change in fertility resulting in the ebbs and flows of population. Such statistics as are available, however, fail to give ample support to this hypothesis. A definite conclusion has not been reached, but it seems probable that a variety of socio-economic factors may play a part.

Whatever the causes, the facts have been noted officially by several governmental pronouncements, which have in some instances attempted to establish measures aimed at reversing the trends. Thomas, for example, mentions the system of family allowances,

³ Cleland, Wendell. The Necessity of Restricting Population Growth in Egypt. *J. Egyptian M. A.* 20: 278 (July) 1937. Bentley, C. A. Population Movement and Birth Restriction. *ibid.* p. 288.

⁴ Thomas, E. W. Cary. Population Problems. *J. State Med.* 45: 514 (Sept.) 1937.

² Burch, G. J. Headed for the Last Census? Part 1. *J. Hered.* 28: 203 (June) 1937.

apparently first started on a large scale in France, and the differential taxes on bachelors, with the spread of both measures to other countries. The aim, usually associated with propaganda, is to promote the cult of the large family. But although the curves of Germany's marriage and birth rates, for example, showed fluctuations at the time of the initiation of the marriage loans, the effect is apparently transient and the curves have continued along much the same lines as were in evidence before the promotion of the scheme.

If the present fertility rates continue in either the same direction or without further decrease, the populations in most countries will in a relatively few number of years show definite decreases in their total numbers. It is not at all certain, however, that this will occur, since at least some of the factors which determine the net changes seem to be entirely beyond human control or prophecy.

Current Comment

EXPERIMENTAL ARTERIAL HYPERTENSION

Many attempts have been made to produce arterial hypertension in laboratory animals by experimental injury to the kidney. Surgical removal of parts of the kidney, bilateral ligation of one or more branches of the renal artery, and local or intravenous injections of nephrotoxic or allergic substances have given inconstant or inconclusive results. Recently Goldblatt¹ described a technic which is an outgrowth of Farr's hypothesis that the essential factor producing persistent arterial hypertension in Bright's disease is reduced renal circulation secondary to renal sclerosis. Goldblatt and his co-workers devised a series of adjustable silver clamps to be placed around the main renal arteries by a retroperitoneal operation. By means of these clamps a permanent "moderate" (33⅓ per cent), "severe" (66⅔ per cent) or "very severe" (90 per cent) reduction in the venous output from each kidney could be produced in both dogs and monkeys. Dogs in which "very severe" bilateral renal ischemia was produced by this technic usually died in about three weeks with typical manifestations of uremic intoxication. With "moderate" or "severe" bilateral renal ischemia, however, both dogs and monkeys survived the operation. Within about six weeks a 100 per cent elevation in systolic blood pressure was noted in dogs, persisting with but slight changes for at least fifteen months. The only subnormal renal function observed was a decrease in "urea clearance" and the blood urea, non-protein nitrogen and creatine remained within normal limits. In monkeys (giant macaques) maximum hypertension was reached in about eight months. At this time one of the monkeys had a systolic blood pressure of more than 300 mm of mercury from a preoperative pressure of 130. The diastolic pressure in this monkey rose from a preoperative level of 90 to 220. Two

possible physiologic mechanisms have been suggested by these investigators: (1) neurologic reflexes from the ischemic kidney cause a generalized vasoconstriction or (2) unknown vasoconstrictor hormones (or other chemical products) are liberated or retained by the anemic kidney. If these hormones exist, however, they have not yet been identified.

ANTISEPTIC PROPERTIES OF HUMAN MILK

In an attempt to demonstrate "inhibins" and bacteria-transforming enzymes in milk, Dold and his co-workers¹ obtained both human and cow's milk in a practically sterile condition by combined antiseptic and aseptic technics. To test for bacteriostatic properties, 5 cc of fresh milk was mixed with an equal volume of 3 per cent melted agar that had been previously cooled to 50 C. The resulting 50 per cent milk agar was poured into a petri dish and allowed to solidify. After solidifying, the milk-agar plate was inoculated with one loopful of a 1:2,000 to 1:4,000 dilution of a twenty-four hour broth culture of the test micro-organisms and the inoculum spread evenly over the surface by means of a glass spatula. The micro-organisms thus tested included the diphtheria bacillus, *Staphylococcus aureus*, streptococcus, *Bacillus coli*, *B. prodigiosus*, *B. pyocyaneus*, *B. anthracis* and an unidentified wild yeast. As controls, the same inoculation was made on heat-inactivated (100 C) 50 per cent milk-agar plates. A profuse (+++) or very profuse (++++) growth was usually noted on the heat-inactivated controls, with no demonstrable growth (—) or only slight growth (+) on the unheated milk-agar plates. Study of the thermostability of the growth inhibiting factor showed that the "inhibins" in cow's milk are not inactivated by heating at 80 C for seven minutes but are destroyed quantitatively by seven minutes' heating at 85 C. In human milk the "inhibins" are completely inactivated by heating at 56 C for thirty minutes. Human milk can be repeatedly frozen and thawed without reducing its "inhibin" titer. Human "inhibins," however, gradually deteriorate on standing, almost complete inactivation being noted after from twelve to twenty-four days' storage in the ice chest (5 C). In their study of the bacteriostatic factors in saliva, these workers had previously shown that saliva which does not completely suppress bacterial growth has the property of transforming virulent diphtheria bacilli into nonpathogenic strains. These transformed strains give subcultures apparently identical with stock strains of the pseudodiphtheria bacillus. Similar salivary transformations of toxic or virulent pneumococci, *B. anthracis* and *B. prodigiosus* have been reported by other investigators.² Practically identical transformations were demonstrated in fresh human milk. The bacteria transforming factors ("mutins") in milk are slightly more heat-resistant than the "inhibins." Thus far, however, no serious attempt has been made to identify the natural milk antiseptics.

Association News

RADIO BROADCASTS

The American Medical Association and the National Broadcasting Company present the fifth series of network health programs beginning Oct 13, 1937, and running weekly through June 15, 1938. The programs will be presented over the Red network each Wednesday at 2 p m eastern standard time, 1 p m central standard time, 12 o'clock noon mountain standard time and 11 a m Pacific standard time.

The dates and topics of the broadcasts for the coming months are as follows:

Hygiene

- November 17—Fresh Air, Fresh Clothes and Fresh Skin ventilation, clothing, bathing
- November 24—Rest, Relaxation, Refreshment all work and no play, or all play and no rest—bad for health
- December 1—Tuberculosis, Foe of Youth how bad habits of hygiene and unwise living, plus infection, favor tuberculosis

Diet

- December 8—It Takes All Good Foods a well rounded diet and how to get it

The stations on the Red network are privileged to broadcast the program but, since it is a noncommercial program, they are not obligated to do so. Interest on the part of medical societies, women's auxiliaries and others may have weight with program directors of local stations. A personal visit to the program director might be advisable if the program is not being taken by a local station. This is an opportunity for the appropriate committees of county medical societies to indicate their interest in having this program broadcast in their community and to enlist the interest of other groups.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

Personal—Among others, Drs Oscar J T Johnston, Batesville, Alexander C Kirby, Little Rock, and William R Brooksher, Fort Smith, have been appointed as members of an advisory council of the maternal and child health division of the state board of health.

District Meetings—The First Councilor District Medical Society held its meeting at Jonesboro, October 14, with the following speakers, among others: Drs John H McCurry, Cash, Congenital Malaria; and Jones H Lamb, Paragould, "Diagnosis and Treatment of Undulant Fever." At a meeting of the Second District Medical Society in Batesville, October 11, Drs Melvin E McCaskill and Merlin J Kilbury, Little Rock, spoke, among others, on "Clinical and Microscopic Study of the Endometrium." The Tenth Councilor District Medical Society was addressed at its all day session in Fort Smith, September 21, among others, by Dr Ray M Balveat Oklahoma City, on "The Therapeutic Value of the Intratracheal Use of Iodized Oil Combined with Eliminative Measures and Specific Desensitization in the Treatment of Intractable Asthma." Dr Oscar J T Johnston Batesville, addressed the Fifth Councilor District Medical Society at Camden October 7, among others, on "Differential Diagnosis of Angina Pectoris and Coronary Occlusion." Speakers before the Third Councilor District Medical Society at Brinkley October 6 included Dr Hugh R Raines, Memphis, on "Diagnosis and Treatment of Common Infections of the Urinary Tract."

CALIFORNIA

Society News—Dr Morris Fishbein, Editor THE JOURNAL will address a special meeting of the San Francisco County Medical Society, November 30 on "The Social Aspects of Medical Care." A banquet will be held in his honor at the Palace Hotel. The society was addressed November 9 by

Drs Albert Lincoln Brown on "Acute Empyema as It Is Treated" and Paul M Aggeler and Salvatore P Lucia, "Studies of the Bleeding and Clotting Mechanisms of the Blood and Its Relation to Clinical Problems."—A symposium on pneumonia was presented before the Alameda County Medical Association, October 18, by Drs Gertrude Moore, Safford A Jelte, Fletcher B Taylor and James B Graesser, Oakland.

CONNECTICUT

Public Health Meeting—The annual meeting of the Connecticut Association of Public Health and Clinical Laboratories was held at Trinity College, Hartford, November 5. The program included the following speakers:

- Friend Lee Mickle, Sc D, director bureau of laboratories, state department of health. The Evaluation Studies on Serodiagnostics Tests for Syphilis
- Dr Louise D Larimore, Greenwich Hospital, Greenwich. Blood Chemistry in Relation to Acidosis
- Dr Jesse G M Bullowa, clinical professor of medicine, New York University Medical College, New York. The Laboratory in the Management of the Pneumonias. (1) Bacteriological and Clinical. (2) Chemical
- Dr William Thalheimer, New York Convalescent Serum. Its Uses and Availability
- Miss Ida Epstein, Hall Wilson Laboratory, Hartford Hospital. The Degree of Acidosis as Determined by Plasma CO Combining Power and Other Laboratory Tests

ILLINOIS

Personal—Dr Joseph A Campbell, managing officer of the East Moline State Hospital, has been appointed acting head of the Anna State Hospital, pending the appointment of a successor to the late Dr Ralph A Goodner. Dr Charles H Starkel, Belleville, was honored October 25, when a fifty year Masonic membership jewel was presented to him by the Grand Lodge of Illinois. He has practiced in Belleville fifty-three years.

Southern Illinois Meeting—The sixty-third annual meeting of the Southern Illinois Medical Association was held in Pinckneyville, November 9. The speakers included:

- Dr Roland M Klemme, St Louis. Management of Head Injuries
- Dr Marion L Klinefelter, St Louis. Early Treatment of Fractures
- Dr Walter C Alvarez, Rochester, Minn. Useful Hints in the Treatment of Indigestion
- Dr Quintan U Newell, St Louis. Treatment of Prolapsus Uteri
- Dr Leon Bromberg, St Louis. Present Status of Artificial Heat Therapy
- Dr William H Olmsted, St Louis. Protamine Insulin
- Dr Frederick V Emmert, St Louis. Analgesia in Obstetrics
- Dr Albert B McQuillan, East St Louis. Rarefying Conditions in Bone Disease

Chicago

Gifts to Medical Library—The library at the University of Illinois College of Medicine has recently received two additions to its collection. Dr William Allen Pusey, Past President, American Medical Association, presented a collection of some 1,500 selected books and an assortment of separates and reports in the field of dermatology, and Dr Arthur E Hertzler, Halstead, Kan, gave a collection of about 7,000 volumes and 8,000 separates, largely in the field of surgery and surgical pathology. Both collections are available to students and the medical profession.

Drs Davis and Koff Awarded Prize—Dr Morris Edward Davis, associate professor of obstetrics and gynecology, and Dr Arthur K Koff, formerly instructor of obstetrics and gynecology, Division of Biological Sciences, University of Chicago, were awarded the annual prize of \$100 by the Central Association of Obstetricians and Gynecologists for the most meritorious work done by its members. Their paper is entitled "The Experimental Production of Ovulation in the Human." Dr Davis won the Gold Medal Award for the best scientific exhibit at the annual session of the American Medical Association in 1935.

Lectures of Institute of Medicine—Dr Alfred H Washburn, director, Child Research Council, University of Colorado, Denver, will deliver a lecture under the Elizabeth McCormick Child Research Grant of the Institute of Medicine of Chicago at a joint meeting of the institute and the Chicago Pediatric Society November 16, at the Palmer House. His subject will be "The Place of Child Research in Medicine. Some Contributions to Medical Thought Suggested by a Study of the Growth and Development of the Individual Child." Dr James B Herrick, professor emeritus of medicine, Rush Medical College, will deliver a public lecture under the auspices of the institute at Thorne Hall, Northwestern University, November 19 on "How Knowledge of the Heart and Its Diseases Has Developed."

Society News—The Chicago Medical Society devoted its meeting November 3 to a discussion on "Recent Developments in the Treatment of Dementia Praecox," the program was

presented by Dr Charles F Read of the Elgin State Hospital and his associates and Dr Major H Worthington of the Research and Educational Hospital and his associates, Dr Read showed a film on "Treatment of Dementia Praecox by Insulin Shock and Cardiazol" and Dr Abraham A Low, assistant director, psychiatric institute, University of Illinois College of Medicine, spoke on "Insulin and Metrazol Shock Treatment of Dementia Praecox and Other Functional Psychoses."—At a meeting of the Chicago Laryngological and Otological Society, November 1, Dr Morris A Glatt discussed "Regeneration of Mucous Membrane After Sinus Operations."—A symposium on sulfanilamide was presented before the Chicago North Shore Branch of the Chicago Medical Society, November 2 by Drs Bernard Fantus, John A Bigler, George S Livingstone and Russell D Herrold

INDIANA

Package Library Service—The extension division of Indiana University now is offering library service to the physicians of Indiana. According to the state medical journal, material has been collected and classified with a view to furnishing an easily accessible loan library service. There is no charge for the service except for the postage.

District Meetings—The Twelfth Councilor District Medical Society will hold its annual meeting at Fort Wayne, November 16. Speakers will include Drs Robert S Berghoff, Chicago, on "More Common Forms of Heart Disease", Everett D Plass, Iowa City, "Female Endocrinology—Practical and Therapeutic Considerations," and Dr Logan Clendenning, Kansas City, Mo.—Speakers before the meeting of the Seventh District Medical Society in Danville, November 3, included Drs Gerald F Kempf on "Sulfanilamide", George W Kohlstaedt "Medical Treatment of Gallbladder Disease," and William V Woods, "Common Foot Ailments and Their Treatment", all of Indianapolis. In the evening Dr Archibald L Hoyne, Chicago, spoke on "Polymyositis."—The Thirteenth District Medical Society was addressed in Mishawaka, November 3, by Drs Alfred S Giordano, South Bend, on "Interpretation of Some of the Common Laboratory Tests as Applied in General Practice", Cleon A Nafe, Indianapolis, "Management of Acute Surgical Conditions of the Abdomen," and Robert W Wilkins, Fort Wayne, "Obstetrics." Drs Edmund D Clark, Indianapolis, president, state medical association, and Charles A Elliott, Chicago, addressed the evening session, the latter's subject was "Cardiac Handicaps."

IOWA

Rotating Intern Service in Polk County—The Polk County Medical Society by agreement with the Iowa Lutheran Hospital, Iowa Methodist Hospital, Mercy Hospital and Broadlawn Polk County Public Hospital (general, tuberculosis and contagious departments), all in Des Moines, is inaugurating a rotating general internship service beginning July 1, 1938, and extending into a two year internship July 1, 1939, according to the *Bulletin* of the Des Moines Academy of Medicine and the Polk County Medical Society. Applications will be received only from graduates of class A medical schools. Rotation of service will include exchange between the individual private institution, which the intern selects and the county hospital. It is planned to select four resident physicians for the year 1939 from the entire group of interns accepted in 1938. Each of the four hospitals will pay its interns \$25 a month and maintenance.

Changes in Health Officers—Dr Erwin C Sage, formerly of Eagle Grove, has been appointed medical director of the Des Moines County Health Unit, succeeding Dr Edwin H Place, who resigned to accept a similar position in Midland County, Mich. Dr Frank J Condon, Fort Dodge, has been appointed director of district health service number 2, which began operations on October 1 with headquarters in Centerville. The district comprises Clarke, Monroe, Decatur, Wayne and Appanoose counties. Dr Joseph H Kinnaman, director of the division of child health and education of the state department of health has been granted a year's leave of absence to take a course in special training at the Johns Hopkins School of Hygiene and Public Health, Baltimore. Dr Chester L Putnam, Holstein, has been appointed field director for the organization of district health service number 3, which is to comprise eight counties.

KENTUCKY

Society News—Drs Oscar O Miller and Joshua B Lukins addressed the Jefferson County Medical Society, Louisville, November 1 on "Silicosis and Postoperative Pulmonary Complications" respectively.—The Louisville Medical Chirurgical Society gave a dinner November 12 in honor of Dr

William E Gardner, Louisville, who was recently elected president-elect of the Kentucky State Medical Association.—Dr George R Livermore, Memphis, Tenn., addressed the Daviess County Medical Society, Owensboro, September 28 on "Prostatic Resection with Two Methods for Treating the Bad Surgical Risk."

LOUISIANA

Society News—A symposium on cesarean section was presented before the Orleans Parish Medical Society, October 25 by members of the New Orleans Gynecological and Obstetrical Society, with one exception, Dr Ansel M Caine, who discussed anesthesia.

The Violet Hart Medal—Prof Reynaldo dos Santos, Lisbon, Portugal, will receive the Violet Hart Medal for the most notable contribution to the advance of vascular surgery, November 26, in New Orleans, where it will be conferred by the committee of award under the auspices of Tulane University. The Violet Hart Fund is a legacy established in honor of Dr Rudolph Matas, emeritus professor of general and clinical surgery, Tulane University of Louisiana School of Medicine. This is the second award of the medal. In January 1934 it was conferred on Dr Mont R Reid, Cincinnati, for his experimental work on the systemic effects of arteriovenous fistulas and his other studies on the peripheral circulation.

MARYLAND

Society News—The Baltimore City Medical Society was addressed October 8 by Drs Jaroslav Hulla on "General Anesthesia by General Practitioners in General Procedures," Harry G Jones, "The Value of Thyroid Medication in Lowered Basal Metabolic Rates Without Myxedema," and William H Pearce, "Recent Rarities in Domiciliary Practice." Among others, Dr William R Geraghty addressed the society, October 22, on "Encephalopathy from the Therapeutic Use of Lead and Opium Pills."

New Health District Opened—The new Southeastern Health District was formally opened, October 15 the third unit to be set up under the Baltimore City Health Department in its program of decentralization of health administration. The district includes all of the first, second and third wards and that portion of the twenty-sixth ward south of Federal Street. The headquarters are at 901 South Kenwood Avenue. Speakers at the dedication included Dr Huntington Williams, Baltimore, commissioner of health, David E Weglen, superintendent of public instruction, and Dr James H Mason Knox Jr, Baltimore, president of the Babies' Milk Fund Association.

MASSACHUSETTS

Personal—Dr Kallman M Davidson, Boston, was guest of honor at a dinner October 12 in recognition of his completion of fifty years in the practice of medicine.—Dr Henry Rolfe Du Puy, formerly of Annapolis, Md, has been named health director of Worcester County, succeeding the late Dr Bradford Massey.

Society News—A round table conference on "Use and Methods of Application of the High Frequency Currents," formed the program of the New England Physical Therapy Society at a meeting in Boston, October 27.—At a meeting of the Hampden District Medical Society in Springfield, October 26, Dr Roger I Lee, Boston, discussed "Coronary Thrombosis: A Clinical Entity That Differs in Practice from Textbook Description."

MICHIGAN

The Beaumont Lectures—Dr Herbert M Evans, professor of anatomy, Morris Herzstein professor of biology and director of the institute of experimental biology, University of California Medical School, San Francisco will deliver the Beaumont Foundation Lectures, under the auspices of the Wayne County Medical Society, Detroit, March 28-29, 1938. The general subject will be "Physiology of the Pituitary Gland."

Highland Park Annual Clinic—The twelfth annual clinic of the Highland Park Physicians Club will be held at the Highland Park General Hospital, December 1. The program will include the following speakers:

Dr Kellogg Speed, Chicago, "Fractures of the Spine."
Dr Claude F Dixon, Rochester, Minn., "Surgical Lesions of the Cranium."
Dr John E Dees, Baltimore, "Sulfanilamide in Gonococcal Infections."
Dr Abraham F Lash, Chicago, "Furteral Serum."
Dr Samuel Isler, Cincinnati, "Deep Infections of the Neck."
Dr Israel M Kalinowitch, Montreal, Que., "Diabetes Mellitus."

Society News—Dr Richard H Overholt, Boston, addressed the surgical section of the Wayne County Medical Society, October 25 on "Surgical Treatment of Primary Carcinoma of

the Lung"—J G Stevenson, chief compensation attorney of General Motors Corporation, addressed the Genesee County Medical Society October 27 on "The Doctor as a Witness"

—The Muskegon County Medical Society was addressed in Muskegon October 22 by Drs Park S Bradshaw and Roy H Holmes, both of Muskegon, on "Respiratory Allergies in Children" and "Fifth and Sixth Venereal Disease" respectively

A Medical Supplement—The Detroit *Free Press* published a medical supplement September 26. On the cover appears an editorial tribute to "The Good Doctor" by Malcolm W Bingay and the special features include signed articles by Dr Thomas Parran, surgeon general, U S Public Health Service, Washington, D C, Dr Morris Fishbein, Editor THE JOURNAL, Chicago, Lawrence Salter, science writer of the *Free Press*, and James A Bechtel, executive secretary, Wayne County Medical Society. The articles discuss a wide range of subjects, including the functions of the glands, urology, pathology, varicose veins and anesthetics

Hospital Upheld in Osteopath Suit—The right of the board of managers of Hurley Hospital to refuse to allow osteopathic practitioners to practice in the hospital was upheld by Circuit Judge Paul V Gadola October 20. Judge Gadola dismissed the motion of L R and H H Kesten, Flint osteopaths, asking a court order allowing them to refer patients to and practice in the municipal institution. The court held that the board has the right to designate who may practice in the hospital as long as the designation is made by class and not against individuals. Ralph M Hueston, Hurley superintendent, testified that the American College of Surgeons and the American Medical Association would refuse to approve the institution if osteopaths were admitted to practice. Attorney Sherman Bean, counsel for the plaintiffs, was assisted by O L Smith of Detroit, representing the state osteopathic association. City Attorney Hymen Hoffman, defense counsel, was aided by Senator Earl W Munshaw, Grand Rapids, counsel for the Michigan State Medical Society

MISSOURI

Twenty-Fifth Anniversary of Library—The Jackson County Medical Society observed the twenty-fifth anniversary of the establishment of the library, November 9, in the auditorium of the Kansas City Municipal Hospital number 1. A feature of the program was the unveiling of a bronze memorial to Rosa M Hibbard, the first librarian of the society who has held the position during the entire twenty-five years. The principal address was delivered by Dr Morris Fishbein, Chicago, Editor of THE JOURNAL, on "The Doctor Makes Literature"

NEW JERSEY

Society News—Dr Zacharias Bercovitz, New York, addressed the Hudson County Medical Society, Jersey City, November 3, on "Diagnosis and Treatment of Ulcerative Colitis," and Dr William G Herrman, Asbury Park, president of the Medical Society of New Jersey, spoke on state activities. —Dr Thomas M Kain addressed the Camden County Medical Society, Camden, November 2 on "Serum in the Treatment of Pneumonia." Dr Hobart A Reimann, Philadelphia, discussed the paper

NEW YORK

Health Department Promotions—Dr Vivian A Van Volkenburgh, health officer of the Ithaca district of the state department of health, has been made assistant state commissioner for local health administration. Dr Ernest L Stebbins, who is in charge of the Rochester district, has been promoted to be director of communicable diseases

Illegal Practitioners Sentenced—The New York State Board of Medical Examiners has recently reported the following convictions of illegal practitioners

George W Schmanke, Rochester, six months in jail and a fine of \$100, jail sentence suspended

William S Dickert, Lockport, one year in jail and a fine of \$500, jail sentence suspended

Frederick T Dennis, Rochester, thirty days in jail and a fine of \$500, the fine suspended on condition that he discontinue his illegal practices

Louis Puff, Lockport, six months in jail and a fine of \$100, both suspended

Thomas Vaughn, Buffalo, one year in jail and a fine of \$500, jail sentence suspended

Prize for Pneumonia Case Reports—A prize of \$100 offered by the advisory committee of the New York State Department of Health for the best report of a series of cases of pneumonia has been awarded to Dr Walter J Karwowski, an intern at the Charles S Wilson Memorial Hospital, Johnson City. The contest was open to all physicians in the state

outside New York City and to interns. Emphasis was placed on the writer's objectivity and his originality and independence in the interpretation of the clinical features. The extent to which new methods of diagnosis and treatment were employed were also taken into consideration. Dr Karwowski graduated from Syracuse University College of Medicine in 1936

Clinical Afternoon and Dinner—The Buffalo Academy of Medicine will present a "clinical afternoon" followed by a dinner at the Hotel Statler, Buffalo, November 17. The following speakers will address the clinical session

Dr Rudolf Schindler, Chicago, Diagnosis of Lesions of the Stomach by Gastroscopy

Dr Robert Louis Levy, New York, Drugs in the Treatment of Diseases of the Heart

Dr Irvn Abell, Louisville, Ky, President Elect of the American Medical Association, Responsibility of the Profession

Dr Richard B Cattell, Boston, Diagnosis and Management of Surgical Diseases of the Colon and Rectum

Dr Morris Fishbein, Chicago, Editor of THE JOURNAL, will be the speaker at the dinner in the evening, on "Social Security and the Physician"

Graduate Courses for County Societies—The committee on medical education of the Medical Society of the State of New York has arranged a course on "The Relationship of Specialties to General Medicine" for the Rockland County Medical Society, which is being given at the Summit Park Sanatorium, Pomona. The series is as follows

Dr Marion B Sulzberger, New York, dermatology, October 22

Dr Marvin F Jones, New York, otology, October 29

Dr Clarence G Bandler, New York, urology, November 5

Dr Ward J MacNeal, New York, the laboratory, November 12

Dr Duncan Macpherson, New York, rhinolaryngology, November 19

Dr Martin Cohen, New York, ophthalmology, November 26

A course on obstetrics was presented before the Cayuga County Medical Society, Auburn, with the following speakers

Dr Ward L Ekas, Rochester, Maternal Welfare, October 7

Dr Edward C Hughes, Syracuse, Toxemias of Pregnancy, October 14

Dr Ferdinand J Schoenck, Syracuse, Complications of Pregnancy, Heart Disease, Diabetes and Tuberculosis, October 21

Dr James K Quigley, Rochester, Delivery Room Problems, October 28

Dr Stuart B Blakely, Binghamton, Hemorrhagic States of Pregnancy, November 4

New York City

Second Harvey Lecture—Dr Einar Lundsgaard of the Institute of Medical Physiology, University of Copenhagen, Denmark, will deliver the second Harvey Society Lecture of the current series at the New York Academy of Medicine, November 18. His subject will be "The Pasteur-Meyerhof Reaction in Muscle Metabolism"

Academy Public Lectures—The second public lecture of the New York Academy of Medicine on the "Art and Romance of Medicine" will be presented November 24 by Dr Alfred E Cohn, on "The Meaning of Medical Research." Dr Harrison S Martland, Newark, N J, will give the third lecture, December 23, on "Dr Watson and Mr Sherlock Holmes"

Staff Appointments at Hospital for Joint Diseases—Six appointments to the house staff of the Hospital for Joint Diseases are available, according to an announcement. The positions are for two years' rotating service on the general service of the hospital. Three are to begin July 1, 1938 and three Jan 1, 1939. Applicants must register before December 15 for the examination which will be held December 27 at the hospital. Further information may be obtained from the director of the hospital, Madison Avenue and One Hundred and Twenty-Fourth Street

World's Fair Medical Director Appointed—Dr Joseph Hoguet has been appointed administrative assistant and medical director of the New York World's Fair of 1939. He will be in charge of executive and administrative work of the division of public health, medicine and sanitation and will be responsible for the health of members of the exposition staff and of visitors attending the fair. Dr Hoguet graduated from Columbia University College of Physicians and Surgeons in 1907 and was at one time assistant professor of clinical surgery at Cornell University Medical School

Friday Afternoon Lectures at the Academy—The twelfth annual series of Friday Afternoon Lectures of the New York Academy of Medicine will begin November 19. The lectures for November and December will be as follows

November 19, Dr Robert L Levy, Drugs in the Treatment of Heart Disease

November 26, Dr Irving H Pardee, Anterior Pituitary—Its Hormones Relative to Diagnosis and Therapy

December 3, Dr Franklin M Hanger Jr, Newer Laboratory Aids and Their Clinical Value

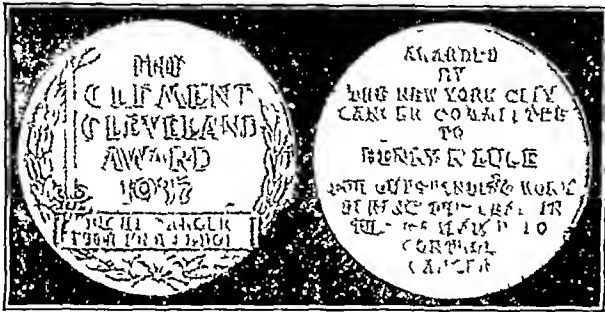

December 10, Dr Isidor S Ravdin, Philadelphia, The Problem of the Jaundiced Patient

December 17, Dr Eugene M Landis, Philadelphia, Recent Advances in the Diagnosis and Treatment of Peripheral Vascular Diseases

Society News—Dr Bradley L Coley addressed the New York Surgical Society, October 27, on "An Efficient Method for the Reduction and Immobilization of Colles' Fracture"

—At a meeting of the New York Endocrinological Society, October 27, the speakers were Drs Bernard Seligman on "Factors in Etiology and Treatment of Obesity", David Anchel, "Dwarfism," and Aaron S Blumgarten, "An Unusual Type of Pituitary Disorder"—Drs Eli Jefferson Browder and Harold Russell Meyers addressed the Medical Society of the County of Kings, October 19, on "A Consideration of Etiologic Factors and Diagnostic Procedures" and Surgical Excision of Epileptogenous Zones in the Brain" respectively—Drs Charles Edward Hamilton, Brooklyn, and Benjamin P Potter, Secaucus, N J, addressed the Brooklyn Thoracic Society, October 15, on "Some Interesting Pathological Conditions Found in the Mediastinum" and End Results of Collapse Therapy" respectively—Speakers before the Medical Society of the County of New York October 25 were Drs Charles Hendee Smith, on "Diagnosis and Prognosis of the More Common Congenital Cardiac Defects", Edwin P Maynard Jr, "Diagnosis and Treatment of Cardiovascular Syphilis", Lucy Du Bois Porter Sutton Management of Acute and Subacute Rheumatic Heart Disease" and Harold E B Pardee, "Diagnosis and Treatment of the More Common Cardiac Arrhythmias"

Publisher Awarded Cancer Medal—Henry R Luce, president of Time, Inc, producer of the "March of Time," was awarded the first Clement Cleveland Medal of the New York City Cancer Committee at a dinner at the Town Hall Club, October 27, "for outstanding work during the year in the campaign to control cancer" The presentation was made by Mrs Robert G Mead, daughter of Dr Cleveland and donor

of the medal Dr Cleveland, who died in 1934, was for many years surgical director of the Woman's Hospital and was one of the organizers of the American Society for the Control of Cancer, which developed from meetings held in his home The award of the medal to Mr Luce was in recognition of a special March of Time motion picture release "Conquering Cancer," featuring the campaign of public education on cancer control Dr Stanley P Reimann, Lankenau Hospital, Philadelphia, represented the American Society for the Control of Cancer Dr Francis Carter Wood and Mr Harford Powell were other speakers in addition to Mr Luce The dinner was held at this time to mark the observance of the eleventh annual Cancer Week proclaimed by Governor Lehman

NORTH CAROLINA

Dr McBrayer Resigns from Tuberculosis Association—Dr Louis B McBrayer, Southern Pines, has retired as managing director of the North Carolina Tuberculosis Association, a position he had held since 1915, when the association was founded Dr McBrayer resigned earlier this year as secretary of the Medical Society of the State of North Carolina Dr Romulus L Carlton, health officer of Winston-Salem, has been appointed managing director of the tuberculosis association He was graduated from the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, in 1906

OHIO

The Hanna Lecture—Dr Cornille Heymans professor of pharmacology University of Ghent, Belgium will deliver the forty-second Hanna Lecture at the Institute of Pathology Cleveland November 18 His subject will be "The Control of Vaso-motor Tonic Blood Supply and Blood Pressure"

Hospital News—Dr David I Abramson Brooklyn, has been appointed director of the department of cardiovascular research at the Jewish Hospital Cincinnati—A thirty-five

bed sanatorium for Tuscarawas County was opened October 1 with Dr William E Hudson as superintendent It is near New Philadelphia

Hospital Centennial—The centennial anniversary of the Cleveland City Hospital was observed at a dinner at the Hotel Cleveland, October 18, attended by several hundred citizens Dr Arthur C Bachmeyer, Chicago, was the principal speaker at the dinner, and a short play picturing episodes in the growth of the hospital was presented

Gifts to the University of Cincinnati—The following gifts to the University of Cincinnati College of Medicine were recently announced

A bequest from the late Dr Augustus Rynogli \$4,250
B H Kroger \$1,200 to provide an assistant resident in orthopedic surgery for the next two years
Parke Davis Company renewed grant of \$1,800
Union Central Life Insurance Company \$650 to establish a fund directed toward a study in the chemistry of heat stroke and heat exhaustion
William S Merrell Company two fellowships of \$600 each for graduate work in surgery

OREGON

State Medical Election—Dr Charles E Sears, Portland, was chosen president-elect of the Oregon State Medical Society, at its annual meeting in Salem, October 21-23 and Dr Charles T Sweeney, Medford, was installed as president The following were elected vice presidents Drs William W Brum, Salem, Richard B Adams, Portland, and Derm P Crowell, North Bend

PENNSYLVANIA

Society News—Dr Russell L Cecil, New York, addressed the Main Line Branch of the Montgomery County Medical Society, Haverford, at a special meeting November 8 on "Pneumonia with Special Reference to Its Specific Treatment"—Dr Edward J G Beardsley, Philadelphia, addressed the Westmoreland County Medical Society, Greensburg, November 2, on "Simplicity in Cardiovascular Diagnosis"—Drs John P Griffith and William Watt G MacLachlan, Pittsburgh conducted the annual fall clinic of the Fayette County Medical Society, Uniontown October 21, at the Uniontown Hospital—Dr Llewellyn W Lord, Baltimore, addressed the Harrisburg Academy of Medicine, October 19, on "Eczema and Allied Dermatological Conditions"

Philadelphia

Ex-Residents' Dinner—The fifty-first annual dinner of the Association of Ex-Resident and Resident Physicians of the Philadelphia General Hospital will be held at the Bellevue Stratford Hotel, December 7 Brig Gen Frank R Keefer retired, Washington, D C, will be the guest of honor and Dr Alfred Stengel will preside Ex residents who do not receive notices are asked to send their correct addresses to the secretary, Dr George Wilson, 133 South Thirty-Sixth Street, Philadelphia

Mr Donner Provides Funds for Study of Cancer—Mr William H Donner, who in 1932 endowed the International Cancer Research Foundation with a gift of \$2,000,000, has given to the University of Pennsylvania \$200,000 to establish a new radiologic department in the University Hospital for the study of malignant diseases, it was announced October 30 Mr Donner made the gift in memory of a son who died in 1931 A new building will be erected for the department, the New York Times reported

Society News—Dr Charles Macfie Campbell, Poston, addressed the College of Physicians of Philadelphia, November 3, on "Emotional Factors in Health and Disease"—Drs Fritz H Lewy and Douglas Macfarlan among others addressed the Philadelphia Laryngological Society, November 2, on "Testing Facial Nerve Paralysis" and "Standards Set for Audiometers—A Review of the Work Done by the Committees of the American Medical Association and the American Standards Association," respectively—Dr Franklin F Snyder, Baltimore, addressed the Obstetrical Society of Philadelphia November 4 on "Intra-Uterine Respiratory Movements of the Fetus and Their Relation to Respiratory Failure at Birth"

Pittsburgh

Society News—The Allegheny County Medical Society observed Pennsylvania Health Day November 5 with a meeting at the Mellon Institute Auditorium under the auspices of the society and the General Health Council The speakers were Dr Thurman B Rice Indianapolis, on "Fundamental Healthful Living" and Mr Leo A Griffith Pittsburgh on "Layman's Dilemma"—At a meeting of the Pittsburgh O

cal and Gynecological Society October 11 the speakers were Drs Eugene A Conti, on "Placenta Accreta", Rosario Charles Nucci, "Melanoma of the Vulva," and Edward F Williams, Altoona, "Abdominal Pregnancy"—Dr George V Foster addressed the Pittsburgh Academy of Medicine October 26 on "Open Reduction and Fixation of Joint Fractures"

SOUTH CAROLINA

Founders' Day—Dr Irving S Cutter, dean and associate professor of medicine at Northwestern University Medical School, Chicago, delivered the address at the annual Founders' Day banquet at the Medical College of the State of South Carolina, Charleston, November 4. During the day the following program was presented

Dr James C McLeod Florence Traumatic Abdominal Surgery
Dr James Heyward Gibbs Columbia Cardiac Pain
Dr Joseph Decherd Guess Greenville Management of the Third Stage of Labor
Dr Frederick L Kredel Charleston Neurosurgical Diagnosis
Dr William H Kelley Charleston Treatment of Lobar Pneumonia

TENNESSEE

Personal—Dr Joseph C Tatum, Pulaski, has resigned as health officer of Giles County and Dr Wilfred N Sisk, assistant director of the health unit, has succeeded him

University News—The University of Tennessee College of Medicine, Memphis, has established three fellowships in radiology, with practical instruction to be offered at the John Gaston Hospital, which has new radiologic equipment and a supply of radium, it is reported in *Science*

Society News—Dr Rudolph H Kampmeier, Nashville, addressed the Davidson County Medical Society, Nashville, October 5, on "Lymphogranuloma Inguinale"—Speakers at a meeting of the Dyer, Lake and Crockett Counties Medical Society, October 6, were Drs Isaac G Duncan, Memphis, "Foreign Bodies in the Bladder" Ernest H Baird, Dyersburg, "Fractures of the Lower Extremity," and Edward G Campbell, Memphis, "Highlights in the Management of Infantile Paralysis"—At a meeting of the Hamilton County Medical Society, Chattanooga, October 14, Dr Hiram A Laws Jr discussed cholecystectomy and Dr Thomas Lyles Davis tracheobronchitis—Among speakers at a meeting of the Hardin, Lawrence, Lewis, Perry and Wayne Counties Medical Society in Waynesboro, September 28, were Drs William K W Sullivan, Jackson, on "Common Errors in the Diagnosis and Treatment of Routine Pediatric Disorders" and William E Boyce, Flatwoods, "Water Balance of the Body"—Drs John L Jelks, Memphis, and Julian H Adler, Western State Hospital, addressed the Memphis and Shelby County Medical Society, September 7, on "Two Unclassified Forms of Colitis" and "The Hypoglycemic Treatment of Dementia Praecox," respectively

TEXAS

Society News—Drs Andrew B Rivers, Rochester, Minn., and Ben R Buford addressed the Dallas County Medical Society, November 11, on "A Study of 5,000 Cases of Indigestion" and "The Newer Treatment of Lobar Pneumonia" respectively—At the fall meeting of the Northwest Texas District Medical Association in Cisco September 14 the speakers included Drs Craig W Munter, Fort Worth, on "Treatment of Urinary Infections with Mandelic Acid", Walter Grady Reddick and Karl B King, Dallas, "Sulfanilamide," and Oliver B Kiel, Wichita Falls, "Iontophoresis with Mecholyl in Treatment of Rheumatism"

VIRGINIA

State Medical Election—Dr Alex F Robertson Jr, Staunton, was chosen president elect of the Medical Society of Virginia at the annual meeting in Roanoke October 12-14 and Dr George Franklin Simpson, Purcellville, was installed as president. The following were elected vice presidents: Drs William L Powell, Roanoke, Jesse M Shackelford, Martinsville and Flavius O Plunkett, Lynchburg. Next year's meeting will be held in Danville

WEST VIRGINIA

Heart Association Meeting—The first midyear meeting of the West Virginia Heart Association will be held November 22 in Charleston. Dr James Edwin Wood Jr, associate professor of internal medicine, University of Virginia Department of Medicine, Charlottesville, will be the guest speaker on "Rheumatic Fever and Rheumatic Heart Disease." Dr William C Stewart, Charleston, is president

GENERAL

Society News—Dr Howard C Naffziger, San Francisco, was named president-elect of the American College of Surgeons at the annual meeting in Chicago, October 25-29. Dr Frederic A Besley, Waukegan, Ill., assumed the presidency. Drs Vernon C David, Chicago, and Fraser B Gurd, Montreal, were elected vice presidents. Next year's congress will be held in New York.

Physician Impersonated by Impostor—It has been reported by the Wayne County Medical Society, Detroit, that a man is using the name of Dr Samuel F Haverstock, Detroit, in contacts with physicians. Dr Haverstock said in a statement to the society that about ten years ago he helped a man who posed as a physician. After the first episode, Dr Haverstock saw the man again and gave him a few dollars. He then disappeared. According to Dr Haverstock, the man, who at that time was about 50 years old, had a pleasing manner and a definite knowledge of medicine. Dr Haverstock has practiced continuously in Detroit since 1909.

Farmer-Swindler in Western States—The sheriff of Cascade County, Mont., reports that a man giving worthless checks for ophthalmic examinations and glasses has swindled several physicians recently in Montana and Minnesota. This procedure was described in *THE JOURNAL*, September 11, page 883. It was said that the man represented himself to be a farmer. His checks given to Montana physicians were marked "For 30 Leghorn hens." According to the latest report he has used the names W P Rogers, Chas Vaughn, J D Heflin, G C Walters and G C Emerson. A physician in Michigan, on seeing the recent notice in *THE JOURNAL*, reported that such a man had visited his office Oct 24, 1936, using the name W E Garner and asking to have glasses mailed to R F D No 2, Galesburg, Mich.

Annual Tuberculosis Seal Sale—The thirty-first annual sale of Christmas Seals sponsored by the National Tuberculosis Association and its constituent state associations will open Thanksgiving Day. This year's seal depicts a Colonial watchman ringing a bell, symbolizing guardianship of life and property. The national association announced in its annual report released October 23 that tuberculosis deaths increased in 1936 after ten years of steady decrease. Available figures indicate that 70,907 persons died of tuberculosis in this country in 1936, as compared with 69,471 in 1935. The death rate was 55.4 per hundred thousand as compared with 54.5 in 1935. The increase was attributed in the report to "cumulative effects of the depression."

Christmas Seals!

Buy and Use Them

Aero Medical Association—At the annual meeting of the Aero Medical Association of the United States at the Waldorf-Astoria, New York, October 1-3, Dr James C Cole, New Orleans, was elected president and Dr Herbert B Wright, Cleveland, first vice president. Among the speakers were the following:

Dr Louis F Bishop Jr, New York, "Is It Safe for the Heart Patient to Fly?"
Drs Ashton Graybiel, Boston, and Vladimir Missiuro, professor of hygiene, Warsaw, Poland, "Experimentally Induced Anoxemia in Cardiac Patients with Special Reference to Certain Hazards in Air Travel and to the Use of Anoxemia as a Cardiac Functional Test."
Ross A McFarland, Ph D, and David B Dill, Ph D, Boston, "Physiological and Psychological Effects of Low Oxygen on Normal Man."
Dr Harry G Armstrong, U S Army, Dayton, Ohio, and J W Heim, Ph D, of the Physiological Research Laboratory, U S Army Factors Influencing Altitude Tolerance During Short Exposures to Decreased Barometric Pressure.

Meeting of Obstetricians and Gynecologists—Dr Ralph A Reis, Chicago, was chosen president elect of the Central Association of Obstetricians and Gynecologists at the annual meeting in Dallas, Texas, October 14-17. Dr Robert D Mussey, Rochester, Minn., was installed as president, Dr William T Black, Memphis, Tenn., was elected vice president and Dr William F Mengert, Iowa City, secretary. Next year's meeting will be in Minneapolis. Dr Charles Macfie Campbell, Boston, was the guest speaker, giving an address on "Personal and Environmental Factors in Obstetrical and Gynecological Practice." Dr John A Kolmer, Philadelphia, was the guest of the Texas Association of Obstetricians and Gynecologists and addressed a joint banquet of the two organizations on "The Etiology, Diagnosis and Treatment of Septicemia with Special Reference to Sulfanilamide."

Fellowships by Research Foundation—Fellowships carrying an annual stipend of \$2,000 will be awarded each year at the annual meeting of the board of directors of the Finney-

Howell Research Foundation, the second Wednesday of March beginning in 1938, according to an announcement. The awards will be for one year with the possibility of renewal up to three years. When deemed necessary by the board, special grants of limited sums may be made to support the work carried on under a fellowship. Applications must be on file at the office of the secretary of the foundation, Dr. William A. Fisher, Medical and Surgical Faculty Building, 1211 Cathedral Street, Baltimore, on or before the first day of February. The Finney-Howell Research Foundation was created under the will of the late Dr. George Walker, Baltimore, to support "research work into the cause or causes and the treatment of cancer." The will directed that the surplus income from the assets of the foundation together with the principal sum should be expended within a period of ten years to support a number of fellowships in cancer research, each with an annual stipend of \$2,000 in such universities, laboratories or other institutions, wherever situated, as may be approved by the board of directors.

Southwestern Medical Meeting in Phoenix—The annual meeting and clinical conference of the Southwestern Medical Association will be held at the Hotel Westward Ho, Phoenix, November 18-20, under the presidency of Dr. Chester R. Swackhamer, Superior, Ariz. A group of speakers will present several addresses each in the general session and conduct clinics and round table discussions. They include:

Dr. Arthur Steindler, Iowa City, Fracture Deformities and Disabilities of the Forearm, The Scoliosis Problem.
Dr. William J. Mellinger, Santa Barbara, Calif., The Base of the Skull.
Chauncey D. Leake, Ph.D., San Francisco, Practical Clinical Applications of Recent Pharmacological Studies.
Central Nervous System Depressant Drugs.
Drugs Used for Diagnosis.
Practical Pharmacology of Heart Drugs.
Charles M. Wheeler, Ph.D., San Francisco, Amebiasis, Unsuspected Tropical Diseases of the Southwest.
Dr. Elmer L. Seeringhaus, Madison, Wis., Physiological Relations Between Pituitary, Gonads and Sex Organs.
Treatment of Disturbances in Menstrual Rhythm and Sterility.
A Review of the Principles and Techniques of Endocrine Therapy.
Dr. Leo Eloesser, San Francisco, Treatment of Chronic Empyema.
Stenosis of the Air Passages.
Dr. Clady R. H. Dick, Evanston, Ill., Poliomylitis, Scarlet Fever.
Dr. Arlie R. Barnes, Rochester, Minn., Coronary Sclerosis, Pulmonary Embolism.

In addition, Dr. Charles A. Bahn, New Orleans, will conduct round tables and clinics in ophthalmology, and with Dr. Mellinger will take part in a special meeting Friday morning for specialists in diseases of the eye, ear, nose and throat. Dr. Swackhamer will deliver his official address at the opening general assembly.

LATIN AMERICA

New Cancer Society—Announcement is made of the formation of the Cancer Society of Rosario, Argentina, for the study of cancer in all its aspects. Dr. Jose M. Cid is president and Dr. C. Sylvestre Begnis is secretary. A special committee has been appointed to organize a campaign against the disease with the following members: Drs. Juan Martinez Begnis, Manuel Gonzalez Loza and Raul Mayer.

Government Services

Miss Roche Resigns from Treasury Department

Miss Josephine Roche, Assistant Secretary of the Treasury in charge of the U. S. Public Health Service since Nov. 15, 1934, resigned November 1. According to the *New York Times*, Miss Roche found it necessary to devote some time to her coal business in Colorado. At the request of President Roosevelt, she will remain as a member of the Interdepartmental Committee for the Coordination of Health and Welfare Activities of the Federal Government of which she has been chairman since its creation by executive order a year ago. Miss Roche is the first woman to occupy the position of Assistant Secretary of the Treasury and the second woman to have attained subcabinet rank.

Changes in U. S. Public Health Service

The following have been appointed and commissioned to the positions indicated in the U. S. Public Health Service:

Dr. George L. Cristy, passed assistant surgeon reserve corps for active duty, U. S. Marine Hospital, Galveston, Texas.
Dr. Robert C. Dunn, assistant surgeon reserve corps for active duty, U. S. Marine Hospital, Seattle.
Dr. Joseph G. Evans, as a assistant surgeon reserve corps for active duty, relief station, San Pedro, Calif.
Dr. Russell K. Taubert, assistant surgeon reserve corps for active duty, U. S. Marine Hospital, Mobile, Ala.

The "Bottle Habit" Under the Insurance System

Addressing the National Association of Insurance Committees, Sir Kingsley Wood, minister of health, said that national health insurance had just attained its jubilee and was a successful and essential part of our social system. The number of insured persons now exceeded 18,000,000 and the benefits distributed since the beginning of the scheme were no less than \$3,000,000,000. He hoped to introduce a bill to make medical benefit available to young persons immediately after they left school and entered insurable employment, thus filling a gap which existed between the school medical service and that provided under the insurance act. He was still concerned with the number of bottles of medicine that were being prescribed to quench what might be described as a national medicinal thirst. In the last twelve months the number of prescriptions issued in England and Wales had increased from 43,800,000 to 66,000,000. Some part of the increase might be due to resort by insured persons to their physicians at an earlier stage of the illness, but the greater part was the result of the growth of the 'bottle habit'. It was not a satisfactory state of affairs, and how to deal with it was not easy to discover.

Medicine and Future Methods of Warfare

Science has profoundly altered not only the methods of warfare but also the medical problems arising from it. In a lecture on "Science and Future Warfare" Prof. J. B. S. Haldane, F.R.S., said that we heard about terrible new gases. It was possible that the list of poisonous volatile compounds was not exhausted, but he did not believe in the probability of anything much worse than mustard gas being produced. It was noteworthy that this gas was well known in 1886 and yet nothing worse was discovered between that date and its use in 1917 in the war. Recalling the measures taken when in 1915 the Germans first used gas against the British troops, he said that his father (the late Prof. J. S. Haldane, the physiologist) was sent to France. After he discovered that chlorine was being used he made experiments and devised within a week a primitive kind of respirator which kept out most of it. An air raid on London in which an enemy staked a big fraction of his air force might kill 50,000 people, but Professor Haldane did not believe that millions would be killed. Calculations about gas were often based on a ridiculous misconception. It had been pointed out that 10 tons of gas properly distributed would render the atmosphere poisonous over an area of several square miles. It was also true that one ton of bullets would kill the entire British army, if correctly aimed. It was not likely that a hostile force would be able to drop bombs exactly where it wished. Until recently he shared the view that incendiary bombs were likely to be most dangerous, but he had been amazed at the slight efficiency of incendiary bombs dropped on Madrid.

MICROBIC WARFARE

There was the boggy of microbial warfare—the use of disease as a weapon. Under one of those conventions which nations did not take seriously, bacteriological warfare was forbidden. But the convention was loosely drafted. Those diseases most likely to be of use in future warfare were not caused by bacteria but by ultramicroscopic viruses. Therefore any power which used this method could claim that it was within international law. He was doubtful whether any method of attack by disease germs would be anything like as effective as

high explosives. It was possible that pneumonic plague might be disseminated by airplanes, but that process was more difficult than it sounded.

FOOD SUPPLIES

With regard to food supplies in time of war, there were many possibilities of assistance from scientists. There was a sporting chance that this country could be made to a large extent independent of food imports by some technic for producing sugar or starch from wood, which could already be done on a laboratory scale.

A Socialist Medical Journal

The first issue of a medical journal called *Medicine Today and Tomorrow* which is the official organ of the Socialist Medical Association, has appeared. Its policy is defined by the question which it poses: "Does the British Medical Association speak for doctors?" It answers as follows: "The British Medical Association says: 'The existing health services do not represent a national health policy. The basis of this should be the provision for every citizen of a general medical practitioner—the family doctor whom no individual and no communal health service can replace.' *Medicine Today and Tomorrow* says: 'The team and not the individual doctor must be the unit of the ideal medical service. Cooperation must replace individualism. Only when the health services are unified can every achievement of modern medical science be freely available to every member of the community.'

The first article, by Mr Somerville Hastings (laryngologist), chairman of the Hospitals and Medical Services Committee of the London County Council, is devoted to "The Municipal Hospitals of London." He says that the labor party (now in power on the council) has been doing its best to induce the citizens to appreciate the fact that they are their own, that each one of them has every right to use them. He mentions reforms introduced by the labor party, such as reduction of the nurses' hours of work from sixty-six hours (in some cases) to a maximum of fifty-four and making the treatment of tuberculosis entirely free. He dilates on the features of the great hospital system of the council, which controls seventy-three hospitals, with 36,000 beds. But these features were in existence before the labor party came into power, though the party naturally has made some improvements. The journal advocates a state medical service for all. An editorial entitled "Medicine and Peace" asks for the international cooperation of the medical profession in the cause of peace, with which all would agree. But the article goes on to represent the precautions against air raids as illusory, which is by no means a foregone conclusion. But in their avidity for antigovernment propaganda the socialists assume it, and the new journal simply repeats

"Delayed Action" Blindness Due to Gas Poisoning in the War

Some 2,000 war-blinded men are still at St Dunstan's, the institute founded for their care. The cases of "delayed action" blindness, due to poison gas used in the war, have not yet ceased to occur. The twenty-second annual report of St Dunstan's shows that fourteen new patients were admitted in the past year, blindness resulting from men having been gassed more than twenty years ago. During the past five years nearly 200 such cases have occurred. The scheme for providing talking books for the blind—phonograph records that will play on specially adapted machines for twenty-five minutes each side, thus enabling an average book to be recorded on ten double-sided 12 inch records—has now become definitely established.

Sir John Thomson-Walker

Sir John Thomson-Walker, who was until his retirement six years ago the leading genito-urinary surgeon in this country, has died at the age of 67 years. Educated at the University of Edinburgh, he graduated in 1894 after a distinguished career as a student. He engaged in postgraduate study at Vienna and

Jena and was appointed surgeon to St Peter's Hospital for Stone and Urinary Diseases, London. In the war he was surgeon to King George Hospital and to King Edward VII Hospital for Officers. In 1919 he was appointed senior urologist and lecturer on urology at King's College Hospital, which was then undergoing reconstruction in a new home. The urologic department was a new one and it therefore fell to him to organize it. His reputation was worldwide, especially for the treatment of enlarged prostate. An excellent operator, he standardized the technic for suprapubic prostatectomy and showed that under favorable conditions the mortality could be reduced to about 2 per cent. He wrote extensively on urology not only in the journals but in the textbooks. His book on "The Surgical Diseases and Injuries of the Genito-Urinary Organs" became the standard work on the subject. He was an honorary member of the urologic societies of America, Austria, France, Germany, Hungary, Portugal and Spain. He played a prominent part in the founding of the Urological Section of the Royal Society of Medicine.

PARIS

(From Our Regular Correspondent)

Oct 16, 1937

International Congress on Hepatic Insufficiency

The meeting of the International Congress on Hepatic Insufficiency was held at Vichy, the health resort, September 16-18, under the presidency of Prof Maurice Loeper of Paris. Many distinguished physicians from all parts of the world, including Dr Whipple of the United States, formed a part of the 1,600 members who attended the meeting. Professor Glaessner of Vienna read a paper on functional tests of hepatic insufficiency. He called attention to the fact that these were not accurate enough, as yet, to base a diagnosis on alone, without taking into consideration the clinical history. Although there are many changes in the parenchyma of the liver which are accompanied by disturbances of function, there are often local changes without evidence of dysfunction. In the major forms of hepatic insufficiency, functional tests are superfluous. In most such cases the clinical observations suffice for diagnostic purposes, but in minor degrees of dysfunction, laboratory tests may be of value.

Professor Castex of Buenos Aires sent a paper on pigmentary hepatic insufficiency. In one form the canaliculi are involved, in the other only a functional disturbance exists. The study of the urobilin and bilirubin in the two forms enables one to distinguish (canalicular lesions) to be distinguished from the other (dysfunction). Dr Urbach spoke on the relation of the liver to the skin. Dysfunction is the direct cause of pruritus, urticaria, impetigo and eczema. These dermatoses can in turn give rise to serious liver disturbances. In such diseases as bronze diabetes, the skin and liver changes go hand in hand.

Dr Parhon of Bucharest read a paper on the endocrine function of the liver. For the present, the secretion of an antianemic hormone must be taken with reserve, though there are numerous relations between the liver and other endocrine glands during muscular activity and digestion. Drs Debre, Gilbrun and Semelaigne reported their observations on hepatomegaly in children. One type is of special interest in which there is an accumulation of reserve substances such as glycogen or fat in the liver parenchyma. Growth is retarded and there is a disturbance of carbohydrate and lipid metabolism. The urine contains ketones. In general, the prognosis is a favorable one.

Drs Lemaire and Vary of Paris spoke on edema due to hepatic dysfunction. Biochemical studies made by them revealed the direct relation between such edemas and cellular changes in the liver as the result of some toxic factor.

Drs Crandall, Ivy, Elton, Bassler and Goldstein of the United States presented a report on the relation of the liver

to nutrition. Hepatic dysfunction has an important part in the etiology of dysfunctions of the cerebrospinal and autonomic nervous systems by acting either directly or in a reflex manner. Altogether, abstracts of 130 papers were presented during the three day session.

Allowances for Large Families

The task of granting special allowances to heads and members of large families was placed in the hands of a special commission in 1916. This organization now has 222 offices in France and distributes allowances to 5,550,000 salaried workers and 1,920,000 families, according to a paper read by Bonvoisin of Paris at the International Congress for Protection of Infancy, held here in July. The total sum for allowances in 1937 will amount to more than two and a half million francs and will rise to four million when the organization has been perfected.

In discussing this paper, Schreiber of Paris criticized the indiscriminate allowances for large families and maintained that a strict medical control should exist in order not to encourage the raising of large families by parents whose mental and physical capacities are far from ideal. Examples have been cited in this connection of parents receiving allowances for large families but, instead of clothing and feeding the children properly, of spending the allowance for drink. In addition to direct allowances in the form of monthly recompense in money, the heads of large families are granted substantial reductions in railroad fares, and especially in the income tax. Since August 1935 all medical students who are members of families having three or more children have been entitled to a 50 per cent reduction in fees, except for laboratory work. The number of those who can benefit from such a reduction in annual medical school fees must not exceed 25 per cent of the enrolment at any school.

Professor Roussy Named Rector of University of Paris

For the first time in the history of the University of Paris or, as it is termed here officially, the Academie de Paris, a member of the medical profession has been called to serve as rector, a position corresponding to that of president in American universities. Prof. Gustave Roussy, on whom this honor has just been conferred, was appointed dean of the medical school here in 1933 and has taken an active part in the reform of the curriculum. The new rector was born in Switzerland of French parents and came to Paris to serve as an intern in the public hospitals here, following which four year service he was appointed head of the laboratory of physiologic pathology in the College de France and in 1925 professor of pathology in the medical school. His earlier contributions to medical literature were in the field of endocrinology, especially the interaction of various glands of internal secretion. Later he paid particular attention to the experimental production of cancer. Many Americans interested in this field have visited the laboratories and clinics at the Institut de cancer, just outside Paris, of which Professor Roussy has been the active head. His work in modernizing the teaching of pathology at the Paris Medical School has been favorably commented on by foreign visitors. Professor Roussy is the leader in the movement to secure more adequate quarters for the various laboratories. Reference has already been made in these letters to the vast series of buildings for this purpose now being constructed on a historic medical site, that of the Hopital de la Charite, not far from the lecture rooms of the final medical years. He is an honorary fellow of many American and European medical societies. The profession can have just cause to feel proud that such an illustrious representative as Professor Roussy has received such a well merited promotion to the position of rector of the University of Paris, in which there are more than 25,000 students.

A Chair of Medicosocial Aid at Paris Medical School

Professor Crouzon, head of one of the neurologic services at the famous Hopital Salpetriere, where Charcot taught, has just been appointed as the first occupant of the chair of medicosocial aid at the Paris Medical School. His reputation as a neurologist and research in the field of occupational diseases and industrial accidents make him eminently fitted to teach the subject of medicosocial aid as a part of the duty of modern medicine.

Hospital Ward Named in Honor of Dr. Chevalier Jackson

It is the custom in French public hospitals to designate the wards by the names of distinguished physicians and surgeons. In the past, this honor has been reserved for French members of the profession. At the suggestion of Dr. Le Mee, head of the Ear, Nose and Throat Service at the Children's Hospital here, a ward in this service is to be called the Chevalier Jackson ward as a recognition of the work of this internationally known specialist, who has just completed two courses for graduates in Dr. Le Mee's service.

A New Journal on Brucellosis

In accordance with a resolution voted at the recent meeting of the International Congress on Brucellosis, a journal entitled the *Archives internationale des brucelloses* will be published. Its aim will be to collect all material relating not only to brucellosis but to other diseases common to human beings and animals. The first number will appear in January 1938. Those desiring information should write to Dr. Josef Julien, Joyeuse, Ardeche, France.

Death of Dr. Henri Beclere

A few weeks ago an erroneous announcement appeared of the death of Dr. Antoine Beclere, the internationally known radiologist and head of that specialty here, who is very active at the age of 83 years. It now appears that the radiologist who died is Henri Beclere, a cousin of the older specialist, who has cooperated with Prof. Pierre Duval at one of the large public hospitals.

Society for the Advancement of Science

The general meeting of the Kaiser-Wilhelm Gesellschaft for the Advancement of Science was mostly given over to the reading of noteworthy scientific papers by directors of the various institutes of the gesellschaft. The crux of this meeting was a paper by Professor Spatz, director of the Kaiser Wilhelm Institute for Brain Research at Berlin-Buch, on "The Trends of Research on the Brain at Various Epochs." After a historical review the author made especial mention of Gall, the nineteenth century German physician who was the first to seek a localization of psychic functions in specific portions of the brain. After Gall, Brocard and Wernicke were able to demonstrate unequivocally the close relation of certain cerebral regions to the function of speech. The work of Professor Spatz himself also tends toward similar conclusions. He attributes a special significance to certain metabolic conditions (presence of iron) and feels that certain cerebral fields are related to definite functions. He then took up the question of psychic functions and their relation to the brain. He cited the observations in this connection that, in obvious cerebral atrophy accompanied by certain pathologic processes in restricted areas of the frontal and temporal lobes, psychic manifestations of a peculiar nature (changes in personality, character and so on) will appear despite the fact that the regions affected had been previously termed "mute" to denote their lack of special function. Spatz designates certain basally situated areas of the brain the 'basal cortices' in view of their possibly crucial importance for the highest psychic functions.

A second and equally interesting lecture was that of Professor Kuhn, director of the Kaiser Wilhelm Institute of Biology in Berlin-Dahlem. His theme was "The Effect of the Hereditary Anlage." He explained how the chromosomes are divided transversely into a plurality of small segments from which the anlage develops. He then stated that if the chromosomes are submitted to roentgen irradiation they will to a certain extent tend to become divided and in this way the hereditary anlage can be arbitrarily altered and destroyed. Kuhn attributes to the cell plasma a special role in the cellular differentiation within the organism, which is directed by the genes. By roentgen mutations it was possible, experimentally, to create new races, usually of lower vitality, than the parent races. Exceptionally, however, the new race showed itself to have greater vitality than the original race. The experiments were performed with a species of the Lepidoptera, the meal-moth. If several mutations were produced by roentgen irradiation, it was frequently possible to compensate the depleted vital capacity thereby. Kuhn believes that he has determined that the gene gives off certain active substances into the blood and that these on their passage through the blood stream are capable of exerting a reaction in susceptible tissues. These so-called gene hormones have, according to Kuhn's investigations, an important part in the development of individual characters, and this fact the author considers of great significance for genetic research.

Incidence of Delayed Treatment of Cancer

Dr H. O. Kleine of the gynecologic clinic of Heidelberg University recently addressed the Heidelberg Medical Society on the incidence of delayed treatment of uterine cancer. He based his conclusions on a material of more than 800 cases observed in the course of the last twenty years. Of these, 684 were cases of carcinoma of the cervix, 128 cases of carcinoma of the corpus uteri. The total number of cases in which treatment was delayed amounted to 385 (56 per cent) of the cervical cancer cases and seventy-five (58.6 per cent) of the cases of carcinoma of the corpus uteri. It is necessary to differentiate cases in which the patient herself is responsible for the delay and cases in which the physician is at fault. Following the standard also in use at the Munich Woman's Hospital a patient is considered to have delayed the treatment of a cancer if she has allowed three months to elapse from the appearance of the initial symptoms until she first seeks medical advice. A physician is considered to have delayed treatment of a cancer if he has prescribed inadequate treatment for a patient for four weeks or more prior to the institution of special anticancer therapy. The proportion of cases in which the patient was guilty of neglect on this basis amounted in Kleine's material to 40 per cent of cervical cancer cases and 45.3 per cent of cases of carcinoma of the corpus uteri. The proportion of cases in which the physician is responsible for the delay amounted to 9 per cent of the cervical cancer cases and 13.3 per cent of the cases of carcinoma of the corpus uteri. Delay is especially dangerous in cancer of the cervix, as the cancer cells are capable of a speedy and extensive invasion of the parametrium and the carcinomatous process thus becomes inoperable.

The following figures for the years 1928 to 1934 illustrate the disastrous consequences of delay in cervical cancer cases. Of cervical cancers not neglected, 74 per cent were operable and 26 per cent inoperable, of neglected cervical cancers only 49 per cent were operable and the other 51 per cent were inoperable.

In 154 cases of cervical carcinoma the patient neglected the disease for six months or less subsequent to the initial manifestations, in 134 cases the corresponding period of delay varied between six months and two years. In forty-eight cervical cancer cases the physician allowed three months or less to elapse from the time of his initial examination of the patient

until the institution of proper therapy, in twenty-six cases this period was between three and eight months. For an improvement of such a state of affairs Kleine recommends among other measures legally compulsory examination of any woman who presents the initial symptoms of cancer, by a physician of her own choosing.

The Fight Against Lupus

Measures taken to combat lupus have frequently been reported in these letters (e.g., *THE JOURNAL*, Oct 24, 1936, p 1400, and Oct 9, 1937, p 1213). Recently the National Insurance Bureau in its capacity of supreme insurance authority has issued a report with regard to the disease. Certain data culled from the complete statement as published are of interest. In the year 1935 there was set aside in addition to the large appropriations for public health service a fund of 300,000 reichsmarks to be expended solely in the interest of those lupus patients who carry insufficient sickness insurance or who are uninsured. In the year 1937 an additional 200,000 marks was allocated for the same purpose. Already the 1935 appropriation has proved to be money well spent. It is of primary importance that lupus should be attacked as early as possible in its course. If this is done the disease can be quickly and inexpensively eradicated. Special hospitals for lupus patients have been found of particular worth in the campaign against the disease. The practitioner should not first undertake to treat lupus outside the hospital by some half measure that is apt to end in failure, the lupus patient should be admitted to one of the special hospitals as speedily as possible. If the foregoing step is taken the prognosis is favorable, especially if the patient is young. Hospitalization should above all not be delayed if the disease appears to be based on a focus of pulmonary or other centrally located tuberculosis. The same applies to cases characterized by tuberculosis of the mucosa, for in this condition lurks the menace of a diffuse dissemination and of a laryngeal or pulmonary involvement. All patients with lupus carcinoma should of course be hospitalized. Virtually all lupus patients should receive hospital care if they come from an environment contaminated with tuberculosis or if they are unable to obtain suitable nutrition at home. It is seen to that all lupus patients who belong to the Sick Insurance receive adequate treatment.

Abdominal Wounds in War

Professor Ottorino Uffreduzzi, head of the Clinic of Surgery of the University of Turin, delivered a lecture to the physicians of the army in Turin. He said that at the beginning of the Great War surgeons made two mistakes in dealing with abdominal wounds. They did not give immediate surgical treatment as near to the firing line as possible, and they showed an optimism as to the prognosis based on statistical reports of the Anglo-Boer, Russo-Japanese, Italo-Turkish and Balkan wars. In these wars abstention from surgical intervention prevailed, and the wounds were caused by bullets less strong than those fired in the Great War, during which many wounds were caused by fragments of shells. As a result of these errors, many of the wounded died in the field. A few months after the beginning of the war the German statistics showed a mortality rate of 90 per cent from abdominal wounds, 70 per cent of the soldiers dying in the battle fields and 20 per cent in medical posts near by. Of the 10 per cent transported to medical posts, 2 per cent died of late complications. The German surgeons had a congress at Brussels in April 1915, during which Schmieden maintained the advisability of early surgical intervention by well equipped surgeons near the battle fields. In the Great War 4 per cent of all wounds were abdominal wounds. So-called Kuttner's wounds, which pierce the abdomen

without injuring the viscera were more frequent in the frontal than in the transverse axis, and they represented 54 per cent of abdominal wounds. In relation to all abdominal wounds the frequency for the intestine was 60.9 per cent, for the liver 16.1 per cent, for the stomach and the kidneys 7.3 per cent, for the mesentery and the vessels 5 per cent, for the spleen 2.7 per cent and for the pancreas 4 per cent. The treatment is surgical, and the best results are obtained from early surgical intervention. The possibilities for early intervention depend on the organization of the surgical services as well as on the condition of war. In mobile warfare it is advisable to transport the abdominally wounded immediately by airplane. This method of transportation was used in the Italo-Ethiopian war. Peritonitis, peritoneal abscess and intestinal occlusion due to scar adhesions are the most frequent late complications of abdominal wounds.

The Calcium Treatment of Eclampsia

Professor Miranda, in a lecture before the Medical Society of Naples, reported on the administration of calcium in the treatment of puerperal eclampsia. Bernardi, he said, showed that the blood of pregnant women undergoes changes of the physical and the chemical constants, with increased osmotic pressure, decreased electrical conductivity, increased viscosity, decreased calcemia and glycemia and an increased amount of potassium in the blood. Miranda used calcium in the treatment of 226 patients with puerperal eclampsia. In eighty-seven cases the treatment consisted of intravenous injections of calcium chloride. In the remaining 139 cases the calcium treatment was given in association with surgical intervention (cesarean section, forceps delivery, change of presentation of the head or embryotomy). The mortality rate was 13.46 per cent for the first group of patients and 18.55 for the second. The treatment gave the best results in women with preclampsic conditions. The mortality for this group was 4 per cent. Calcium therapy can be given in association with other symptomatic or complementary treatment or with surgical intervention. It gives better results than treatment with magnesium sulfate. Calcium depresses the nervous system, lowers the blood pressure and sends water from the tissues to the blood. Magnesium may be dangerous to respiration without controlling the grave symptoms of eclampsia.

Discussion of Vaccination

A meeting for the discussion of the vaccination problem was held at Utrecht under the auspices of the local medical society. Prof. J. M. Baart de la Faille spoke in favor of compulsory vaccination. He said that the temporary but prolonged suspension of the vaccination law of 1872 has given rise to a nationwide state of inadequate vaccination, especially among the young generations. The speaker advocates compulsory vaccination of infants between the ages of 6½ and 18 months. The children to be vaccinated should be selected by medical examination, religious scruples and conscientious objections should be respected. The medical profession ought to conduct a campaign for public instruction in the benefits of vaccination. The circumstances in which the procedure is contraindicated should also be described. If the public remains uninfluenced by this campaign the medical profession should seek remedial legislation.

W. Schummans-Stekhoven, physician and lawyer, defended the opposite thesis according to which any compulsory medical treatment which inflicts bodily injury should be rejected. Moreover, several risks inhere in vaccination especially for infants under 2 years of age and even after careful selection. In fine, this speaker believes that, if compulsory vaccination is reintroduced,

no penalties ought to be imposed on transgressors of the law, and the right of compensation for untoward sequelae of vaccination ought to be recognized.

Nutrition of the Unemployed of Utrecht

The communal council of Utrecht discussed the problem of nutrition among the unemployed. It was decided to appoint a committee of investigation, named to serve were Prof. J. M. Baart de la Faille, president of the Sanitary Commission and professor emeritus of the University of Utrecht, and in addition Messrs. L. K. Wolff, P. H. Van Der Laan and M. H. Tropp, assistant to Dr. M. A. Tellegen. A number of homes of employed workers, both insured and uninsured, will be visited for the acquisition of information on the food supply. Among the homes to be inspected will be those situated in communes that provide medical care and other benefits (notably free meals for children at school). It will thus be determined whether or not the food allowances for households having children of school age or older are adequate. The directors of labor and unemployment insurance organizations will be furnished a list of homes investigated. The committee will also investigate the nutritional condition of school children and determine which schools provide meals for the pupils and which do not. The reasons for failure of a school to feed its pupils will be sought. If this investigation establishes the existence of malnutrition, there will follow a more extensive survey and the aggregate of data will provide a basis for the comparative study of the individual family's resources.

Marriages

JOSEPH PALMER CAIN JR., Mullins, S. C., to Miss Eleanor Grace White of Lynn, Mass., in Marblehead, Mass., August 17.

J. WALTER TROVELL, Surg., Lieut. Commander, U. S. Navy, San Diego, Calif., to Miss Miriam Kalb of Monrovia, August 15.

EUGENE WILLARD GREEN, Paterson, N. J., to Miss Frances Leonora Monteith of Columbia, S. C., September 15.

EDWARD W. GROVE, Gainesville, Ga., to Miss Margaret Hazel Whelchel of Fresno, Calif., in Atlanta, August 31.

JOSEPH CHARLES ANDERSON, Ebensburg, Pa., to Miss Kathryn Amelia Cooley of Sea Girt, N. J., September 7.

MERRILL ODOM HINES, Chattanooga, Tenn., to Miss Margaret McLaurin Davis in New Orleans, August 24.

BYRN WILLIAMSON, Milton, Tenn., to Miss Katherine Baxter of Asheville, N. C., at Shelbyville, August 8.

WILLIAM ALEXANDER READ, Cleveland, to Miss Emily Haile Sanford of Newport News, Va., August 26.

THOMAS ADDISON MORGAN, Franklin, Va., to Miss Margaret Virginia Ellis of Ashland, September 4.

CHARLES LEWIS BITTINGER, Statesville, N. C., to Miss Lola Irene Harper of Shelby, July 21.

JOHN J. SHAW, East Orange, N. J., to Miss Jane Levy of Shreveport, La., September 9.

LEWIS THORNE HINES, Baltimore, to Miss Helen Preston Ellis of Wellesley, Mass., August 21.

JOSEPH B. GREENE, to Miss Sarah Lyle Spencer, both of Asheville, N. C., in August.

LFE SHARP, Columbus, Ohio, to Miss Alice Holt of Birmingham, Ala., in September.

JOHN JOSEPH HANLON, Chicago, to Miss Mayme Mangan, in Evanston, Ill., August 31.

WILLIAM A. H. RFTTBERG, to Miss Esther Fredricka Rice, both of Denver, in July.

WINTHROP WETHERSEE JR., Boston, to Miss Carolyn Hall of Brookline, in September.

HAROLD A. VINSON, Denver, to Miss Doris Alice Owen of Oklahoma City, July 3.

HAL DAVIS, to Miss Frances Holman Willis, both of Knoxville, Va., August 28.

JAMES DEAN CREGER, St. Paul, Va., to Miss Margaret Long, August 9.

Deaths

Virgil Francis Dinsmore, Tifton, Ga., Georgia College of Eclectic Medicine and Surgery, Atlanta, 1900, Bennett College of Eclectic Medicine and Surgery, Chicago, 1901, member of the Medical Association of Georgia, past president of the Tift County Medical Society, on the staff of the Coastal Plain Hospital, aged 61, died, August 24, of cardiorenal disease and arteriosclerosis

John Herschel Cary, Washington, Pa., Jefferson Medical College of Philadelphia, 1897, member of the Medical Society of the State of Pennsylvania, past president of the Washington County Medical Society, served during the World War, for many years court and jail physician, on the staff of the Washington Hospital, aged 63, died, August 18, of coronary thrombosis

Andrew Boak Alexander, Winnipeg, Manit., Canada, Manitoba Medical College, 1897, at one time assistant professor of clinical medicine (infectious diseases) at his alma mater, formerly medical superintendent of the Winnipeg Municipal Hospitals, aged 65, died, September 3, in the Winnipeg General Hospital, of malignant tumor of the acoustic nerve and of the bladder

Benjamin Jephthah Bill, Genoa City, Wis., Rush Medical College, Chicago, 1879, an Affiliate Fellow of the American Medical Association, an organizer of the Walworth County Medical Society and its first president, helped to organize his district medical society and served one year as president, aged 86, died, August 22, of carcinoma of the pylorus

Hugh F. Keating, New Haven, Conn., Yale University School of Medicine, New Haven 1908, formerly member and president of the board of education, served during the World War, clinical assistant in neurology at his alma mater, 1910-1922, and clinical instructor, 1922-1924, aged 58, died, August 6, of coronary occlusion and arteriosclerosis

Richard Dresser Small, Portland, Maine, Harvard University Medical School, Boston, 1898, member of the Maine Medical Association and the New England Surgical Society, fellow of the American College of Surgeons, formerly on the staff of the Maine General Hospital, aged 65, died, September 11, of carcinoma of the liver

Henry Prentiss Derry, Macon, Ga., University of Georgia Medical Department, Augusta, 1888, member of the Medical Association of Georgia, on the courtesy staff of the Oglethorpe Private Infirmary, served on the staffs of the Mount De Sales Academy and St. Stanislaus College, aged 74, died, August 30, of myocarditis

Harry B. Fralic, Orlando, Fla., Medico Chirurgical College of Philadelphia 1905, formerly connected with the department of Indian affairs, public health service and veterans administration, served during the World War, aged 56, died, August 11, in the Veterans Administration Facility, Bay Pines

Raymond Hansford Leu, New Martinsville, W. Va., University of Tennessee College of Medicine, Memphis, 1917, served during the World War, formerly secretary of the Tyler-Wetzel Counties Medical Society, on the staff of the Wetzel County Hospital, aged 43, died suddenly, August 9

William Edward Colgin, Waco, Texas, Loyola University School of Medicine, Chicago, 1929, member of the American Academy of Ophthalmology and Oto-Laryngology, on the staff of the Colgin Hospital and Clinic, aged 37, was accidentally electrocuted September 10

Everett Willoughby Gould, New York, Columbia University College of Physicians and Surgeons, New York 1899, served during the World War, on the staff of St. Luke's Hospital, trustee of Columbia University, aged 63, died, August 18, of coronary thrombosis

John William Black, Bryan, Texas, Southwestern University Medical College, Dallas, 1909, past president and secretary of the Brazos-Robertson Counties Medical Society, for several years health officer of Bryan, aged 51, died, August 27, of coronary occlusion

Charles F. Sexauer, Newcastle, Ind., Western Reserve University Medical Department, Cleveland, 1884, College of Physicians and Surgeons, Baltimore, 1894, on the staff of the Indiana Village for Epileptics, aged 78, died, August 1, of pericardial aneurysm

Martin C. Barber, Steilacoom, Wash., College of Physicians and Surgeons of Chicago, 1891, member of the Washing-

ton State Medical Association, aged 69, died in August at St. Joseph Hospital, Tacoma, of heart disease following a hernia operation

William Roswell Gillett, Cuero, Texas, University of Nashville (Tenn.) Medical Department, 1896, past president of the DeWitt County Medical Society, for many years president of the school board, on the staff of the Burns Hospital, aged 69, died, July 30

Mary Shepherd Danforth, Manchester, N. H., Woman's Medical College of Pennsylvania, Philadelphia, 1875, member of the New Hampshire Medical Society, aged 87, died, August 6, in the Lucy Hastings Hospital, of myocarditis and arteriosclerosis

William Judd Crookston, Harrisburg, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1904, served during the World War, aged 61, died, August 9, in the Mount Sinai Hospital, New York, following an operation for appendicitis

Bayard Taylor Crane, Rutland, Mass., Harvard University Medical School, Boston, 1901, member of the American Clinical and Climatological Association, medical director of the Central New England Sanatorium, aged 58, died suddenly, August 14

Thomas Jefferson Evans, Colorado Springs, Colo., Hahnemann Hospital College of San Francisco, 1900, medical director and owner of the Crestone Heights Sanitarium and Hospital, aged 66, died, August 4, in Auburn, Wash., of cardiac disease

Samuel Hopkins Spalding, Hingham, Mass., Boston University School of Medicine, 1884, formerly member of the school committee, aged 80, died, August 30, in the Massachusetts Memorial Hospitals, Boston, of arteriosclerotic heart disease

William Gilbert Cole, Cornelius, Ore., Jefferson Medical College of Philadelphia, 1893, formerly member of the state legislature, aged 73, died, August 3, in the Good Samaritan Hospital, Portland, of diabetes mellitus and gangrene of the foot

William Henry Greer, Sheffield, Ala., Chattanooga (Tenn.) Medical College 1900, fellow of the American College of Surgeons, on the staff of the Colbert County Hospital, aged 59, died, August 9, in St. Mary's Hospital, Rochester, Minn.

William Richard Clyburn, Camden, S. C., University of Maryland School of Medicine, Baltimore, 1890, member of the South Carolina Medical Association, on the staff of the Camden Hospital, aged 69, died, August 11, of coronary occlusion

Garret W. Davelaar, Milwaukee, Milwaukee Medical College, 1897, member of the State Medical Society of Wisconsin, formerly medical examiner for the Prudential Life Insurance Company, aged 61, died, August 18, of cardiorenal disease

Emma M. Meinhardt Easterday, McCook, Neb., Hahnemann Medical College and Hospital, Chicago, 1885, Cincinnati College of Medicine and Surgery, 1897, aged 75, died, August 9, of carcinoma of the breast with metastasis to the lungs

Edward H. Elmendorf, San Antonio, Texas, University of Texas School of Medicine, Galveston, 1899, member of the State Medical Association of Texas, formerly city health officer, aged 59, died, August 7, of atherosclerosis

Owen W. Cochran, Boonville, Mo., Louisville (Ky.) Medical College, 1885, member of the Missouri State Medical Association, also a probate judge, aged 77, died suddenly, August 29, of acute myocarditis and enterocolitis

William Clemmons Fogerty, Worcester, Mass., Jefferson Medical College of Philadelphia, 1883, member of the Massachusetts Medical Society, aged 78, died, August 31, of carcinoma of the prostate and cerebral thrombosis

Albert Field, Springfield, Mass., Long Island College Hospital, Brooklyn 1877, member of the Connecticut State Medical Society, aged 93, died, August 25, in a local hospital, of hypertrophy of the prostate and arteriosclerosis

Ephraim B. Chenoweth, Seymour, Ind., Medical College of Indiana, Indianapolis 1902, served during the World War, aged 56, died, August 24, in the Schneck Memorial Hospital, of diabetes mellitus and hyperthyroidism

Harley Ross Colver, Chicago, Rush Medical College, Chicago 1904, medical superintendent of the Carnegie-Illinois Steel Corporation Hospital, aged 63, died, August 22, of coronary thrombosis and arteriosclerosis

Ernest Franklin MacVane, Portland, Maine, University of Vermont College of Medicine, Burlington 1907, member of the Maine Medical Association, aged 57, died suddenly, September 9, of coronary thrombosis

Emory J Drury, Fulton, N Y, University of Buffalo School of Medicine, 1879, for many years county coroner and formerly health officer of Fulton, aged 83, died, August 24, of chronic nephritis and myocarditis

Frank W Black & Ligonier, Ind, Bellevue Hospital Medical College, New York, 1897, aged 65, died suddenly, August 16, of heart disease, after completing a tonsillectomy at the Lakeside Hospital, Kendallville

Henry Rogers Bentley & Central Bridge, N Y, Albany (N Y) Medical College, 1898, past president of the Scholastic County Medical Society, aged 64, died, August 19, of angina pectoris and arteriosclerosis

William Simpson Groom, Conway, Iowa, College of Physicians and Surgeons, Keokuk, Iowa, 1882, member of the Iowa State Medical Society, aged 78, died, August 4, of carcinoma of the stomach

William Edgar Derry, Dover, N J, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1880, aged 81, died, August 4, of cerebral hemorrhage and arteriosclerosis

Herbert V Beardsley, Findlay, Ohio, Homeopathic Hospital College, Cleveland, 1883, formerly secretary of the school board, aged 78, died, August 19, of arteriosclerosis and bronchopneumonia

James Patterson MacFarlane & Indiana, Pa, Jefferson Medical College of Philadelphia, 1905, for many years bank president in Vintondale, aged 59, died, September 4, of coronary thrombosis

Frederick William Derby & Boston, Tufts College Medical School, Boston, 1906, formerly ophthalmologist to the city department of health, aged 62, died, September 4, of coronary thrombosis

Morris Whitfield Clouse, Kearny, N J, University and Bellevue Hospital Medical College, New York, 1899, aged 60, died, August 27, of carcinoma of the cervical glands with metastasis

Howard John Black, Hawthorne, Nev, University of Nebraska College of Medicine, Omaha, 1933, aged 33, died, July 25, in San Francisco, following an operation for brain tumor

Sydney J Baker & Richmond, Va, College of Physicians and Surgeons, Baltimore, 1890, for many years coroner for South Richmond, aged 73, died, August 7, of strangulated hernia

Charles Delamere Wall, Chicago, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900, aged 60, died, August 10, in Manteno, Ill

Edward Cox Mann, San Diego, Calif, University of Buffalo School of Medicine, 1902, aged 62, died, August 5, in the Mercy Hospital, of coronary occlusion and arteriosclerosis

James Thomas Bell, Daisy, Tenn, Vanderbilt University School of Medicine, Nashville, 1890, member of the county school system, aged 86, died, August 29, of bronchopneumonia

Lemont Addison Gates, Bridger, Mont, College of Physicians and Surgeons, Keokuk, Iowa, 1898, aged 64, died, August 29, in St Vincent's Hospital, Billings, of lethargic encephalitis

Zemach Levin, Los Angeles, Julius-Maximilians-Universität Medizinische Fakultät, Würzburg, Bavaria, Germany, 1895, aged 67, died, July 28, of perforated duodenal ulcer

George Irwin Royce, Glendale, Calif, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1877, aged 86, died, July 25, of carcinoma of the pancreas

Fred Morgan Barney, Dolgeville, N Y, Albany (N Y) Medical College, 1888, veteran of the Spanish-American and World wars, aged 74, died, August 17, of angina pectoris

John Wallace Beardsley, Tecumseh Mich, Northwestern University Medical School, Chicago, 1906, aged 55, died, August 19, of supradiaphragmatic esophageal diverticulum

John Douglas Camerer, Glendale, Calif, Rush Medical College, Chicago 1880, also a pharmacist, aged 80, died, August 28, of chronic myocarditis and pulmonary edema

Alice Huff Crandall, San Diego Calif, Omaha Medical College 1884, Woman's Medical College Chicago, 1887, aged 74, died, August 17, of arteriosclerosis and pneumonia

George Henry Dobson, Santa Ana Calif, Cleveland College of Physicians and Surgeons, Medical Department of the University of Wooster 1891, aged 75, died, July 28

Harry T Dunbar, Washington D C, Cincinnati College of Medicine and Surgery, 1876, Civil War veteran, aged 93, died August 24, of bilateral pneumonia

Simon Bismark Casselman, Sault Ste Marie Ont., Canada, Queen's University Faculty of Medicine, Kingston, 1907, died, August 27, of coronary thrombosis

William R Fall, North Vernon, Ind, Medical College of Ohio, Cincinnati, 1879, Civil War veteran, bank president, aged 89, died, August 11, of arteriosclerosis

Martin Josef Fiala & Duluth, Minn, Western Reserve University School of Medicine, Cleveland, 1930, aged 36, died, August 10, at Rochester, of a brain tumor

John L Hutchins, Bicknell, Ind, Kentucky University Medical Department, Louisville, 1904, city health officer, aged 68, died, August 10, of Hodgkin's disease

Armin Greenhut & Dundalk, Md, Medizinische Fakultät der Universität Wien, Austria, 1923, aged 39, was found dead, August 6, of potassium cyanide poisoning

John F Busey, Frisco City, Ala, Medical College of Alabama, Mobile, 1894, aged 72, died, August 17, of carcinoma of the right axilla and cerebral hemorrhage

William Colladay Robinson, Philadelphia, Medical Surgical College of Philadelphia, 1903, aged 75, died, August 6, of prostatic carcinoma with metastasis

George B Hansel & Canton, Ohio, Jefferson Medical College of Philadelphia, 1906, aged 62, died, August 12, of cerebral hemorrhage and coronary thrombosis

Charles Sumner Boggs, Filley, Neb, University of Nebraska College of Medicine, Lincoln, 1884, aged 80, died, August 1, of cerebral hemorrhage

William Gillispie Attwood & Los Angeles, University Medical College of Kansas City, Mo, 1906, aged 58, died, July 14, of coronary thrombosis

Thomas W Curry, Southport, Ind, Medical College of Indiana, Indianapolis, 1885, aged 91, died, August 22, of chronic myocarditis and arteriosclerosis

Caroline Connell Conn, Los Angeles, Chicago College of Medicine and Surgery, 1914, aged 68, died, July 2, of chronic myocarditis and appendectomy

Ulysses W Showalter, Clarksburg, W Va, Baltimore Medical College, 1892, for many years a member of the school board, aged 79, died, July 13

Delmar H Smith & Richmond, Kan, Kansas City (Mo) Medical College, 1896, aged 66, died, July 19, in the Ransom Memorial Hospital, Ottawa

Leander Orr Carruth, Tupelo, Miss, University of Tennessee Medical Department, Nashville, 1882, aged 80, died, August 29, of heart disease

Charles Hewitt, Wakefield, Kan, University of Maryland School of Medicine, Baltimore, 1868, aged 92, died, July 9, in Manhattan, of heart disease

Lindley Hoag Henley, Santa Cruz, Calif (licensed in Oklahoma under the Act of 1908), aged 80, died, July 23, of endarteritis obliterans

George W Shelton, Los Angeles, St Louis College of Physicians and Surgeons, 1883, aged 89, died, July 4, of carcinoma of the tongue

John J Moore, Brooklyn, Ont, Canada, Trinity Medical College, Toronto, Ont, 1891, aged 75, died, August 11, of coronary thrombosis

Max John Alexander & Pocomont, Va, Medical College of Virginia, Richmond, 1910, aged 50, died, August 30, of coronary occlusion

Abbie Blodgett, Benicia, Calif, Physio-Medical College of Indiana, Indianapolis, 1897, aged 82, died, July 3, of chronic myocarditis

Marshall M McGehee, Clarkston, Ga, Southern Medical College, Atlanta, 1888, aged 80, died, July 27, of carcinoma of the stomach

Timothy L Conroy, Baltimore, College of Physicians and Surgeons, Baltimore, 1892, aged 72, died, August 30, of coronary thrombosis

Joseph Harry Welch, Bennington, Vt, University of Vermont College of Medicine, Burlington, 1919, aged 39, died, July 11

James Buchanan Powell, Nashville, Tenn, Vanderbilt University School of Medicine, Nashville, 1889, aged 80, died, July 24

Joseph McCrary, Bold Spring, Tenn (licensed in Tennessee in 1889) Confederate veteran, aged 93, died in July

Maurice William O Connell, San Francisco, California, Medical College San Francisco, 1899, aged 63, died, July 6

James S Hansberry, Wonevot, Wis, Milwaukee Medical College 1905, aged 64, died August 27 of portal cirrhosis

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE The abstracts that follow are given in the briefest possible form (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the composition, (4) the type of nostrum, (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which may be considerably later than the date of the seizure of the product]

White's Herb Tonic—John W. White trading as Dr. J. W. White and White's Herb Mfg. & Remedy Co. Bessemer Ala. Composition Essentially extracts of plant drugs alcohol (under 1 per cent) and water. Fraudulently represented as a remedy for syphilis, rheumatism, pellagra, appendicitis, etc.—[N J 24642 April 1936]

Anti Caps—Arthur Petrie trading as Anti Caps Co. Oklahoma City. Composition Petrolatum and wax with small amounts of menthol and wintergreen. For cancer, vaginal ulcers, etc. Not antiseptic as claimed. Fraudulent therapeutic claims.—[N J 24643 April 1936]

Phospho—Mobile Drug Co. Mobile Ala. Composition Essentially sodium phosphate, phosphoric acid and water. For rheumatism, stomach liver and kidney disorders, etc. Fraudulent therapeutic claims.—[N J 24644 April 1936]

White Cross Quinine and Iron Tonic—John H. Cash trading as American Drug Co. Mobile Ala. Composition Quinine sulfate, epsom salt and an iron compound. For chills, fever, influenza, etc. Fraudulent therapeutic claims.—[N J 24645 April 1936]

McClellan's Orthosol—McClellan Products, Ltd. Los Angeles. Composition Soap, water, tar acids and glycerin. For insect bites and stings, douches, etc. Not antiseptic. False and misleading therapeutic claims.—[N J 24654 April 1936]

Cheney's Compound Herbs—G. S. Cheney Co. Inc. Boston. Composition Coarsely ground drugs including pipsissewa, cascara, yellow dock, dandelion, pricklyash, sassafras, sarsaparilla, red clover and gentian. Blood purifier, etc. Fraudulent therapeutic claims.—[N J 24655 April 1936]

Fellows' (Dr.) Headache Powders—Clark Medicine Co. Newburyport, Mass. Composition Essentially acetanilid (about 2.8 grains per powder of average weight), caffeine (about 0.62 grain per powder of average weight), baking soda and ground plant material including ginger. Fraudulent therapeutic claims.—[N J 24657 April 1936]

Holbrook's India Koff Kure—Holbrook & Co. Lynn, Mass. Composition A syrup containing plant extracts, alcohol (10.4 per cent by volume) and chloroform (1.08 minims per fluidounce). Fraudulent therapeutic claims.—[N J 24658 April 1936]

Femasept—Chemical Laboratories, Inc. Atlanta, Ga. Composition Essentially starch, milk sugar, small amounts of Rochelle salt, talc, common salt and not more than a trace of sodium dichlorosulfamid benzoate. For female disorders. Fraudulent therapeutic claims.—[N J 24659 April 1936]

Dia Bet—Dia Bet Laboratories, Detroit. Composition Essentially water with small amounts of sodium benzoate and extracts of plant material including myrrillin. Fraudulently represented as a cure for diabetes when taken by mouth.—[N J 24660 April 1936]

Cozzins New Formula for Asthma—Cozzins Chemical Co. Brooklyn. Composition Essentially saltpeter, plant material including stramonium leaves and mustard seed, flavored with amse. Fraudulent therapeutic claims.—[N J 24661 April 1936]

Elixir Amplirin—W. Scott Hunt, Oxford, N. C. Composition Essentially salicylic acid (20.6 grains per fluidounce), acetanilid (6.45 grains per fluidounce), alcohol (30.7 per cent), extracts of plant materials and water. For la grippe, nervousness, etc. Fraudulent therapeutic claims.—[N J 24662 April 1936]

Scott's Nose and Throat Drops—Scott Drug Co. Charlotte, N. C. Essentially a mineral oil containing menthol, mint, eucalyptol and wintergreen and not more than a trace of ephedrine. For hay fever, catarrh, etc. Fraudulent therapeutic claims.—[N J 24663 April 1936]

Marleo Ointment—Marleo Chemical Co. New Ulm, Minn. Composition Essentially red lead, lead carbonate and a small amount of volatile oils including turpentine and menthol incorporated in fat. For open wounds, blood poisoning, rheumatism, abscesses, etc. Fraudulent therapeutic claims.—[N J 24664 April 1936]

Antiseptine—Hygienic Pharmacal Laboratories and Genius Pharmacal Laboratory, New Haven, Conn. Composition Essentially alcohol, water and horic, henzoic and salicylic acids with small amounts of witch hazel, thymol, eucalyptol and menthol. For rheumatism, dandruff, tonsillitis, etc. Fraudulent therapeutic claims.—[N J 24670 April 1936]

Tussamag—Robert M. Froehlich trading as Right O Products Co. New York. Composition Essentially extracts of plant drugs including thyme, a saponin, glycerin, sugar, alcohol and water. For bronchial disorders, tuberculosis, etc. Fraudulent therapeutic claims.—[N J 24667 April 1936]

Kay's Ointment—Kraupner & Kraupner, Inc. Brooklyn. Composition Essentially zinc and bismuth compounds and benzocaine in a mixture of petrolatum and wool fat. For leg ulcers, etc. Fraudulent therapeutic claims.—[N J 24668 April 1936]

Kay's Powder—Kraupner & Kraupner, Inc. Brooklyn. Composition Sodium perborate. For leg ulcers, etc. Fraudulent therapeutic claims.—[N J 24668 April 1936]

Kay's Leg Oil—Kraupner & Kraupner, Inc. Brooklyn. Composition Essentially cottonseed oil perfumed with lavender oil. For leg ulcers, etc. Fraudulent therapeutic claims.—[N J 24668 April 1936]

Sullivan's Indian Oil—Sullivan Oil Co. Manchester, N. H. Essentially mustard oil, wintergreen, oleoresin of red pepper, kerosene oil and a fatty oil. For catarrh, croup, asthma, influenza, etc. Fraudulent therapeutic claims.—[N J 24665 April 1936]

Genius Vaporine Ointment—Hygienic Pharmacal Laboratories and Genius Pharmacal Laboratory, New Haven, Conn. Composition Essentially white petrolatum with volatile oils including eucalyptus and menthol. For tonsillitis, catarrh, inflammations, etc. Fraudulent therapeutic claims.—[N J 24670 April 1936]

Victory Vapor Balm—Hygienic Pharmacal Laboratories, New Haven, Conn. and V. V. B. Co. Denver, Colo. Composition Essentially volatile oils including eucalyptus and cajuput (2.2 per cent) in a petrolatum and paraffin base. For catarrh, tonsillitis, asthma, etc. Fraudulent therapeutic claims.—[N J 24670 April 1936]

Thymoform—Chemical Industrial Co. Providence, R. I. Composition Essentially water, formaldehyde, soap, glycerin and volatile oils including thymol and eucalyptol. Fraudulently represented as a disinfectant and deodorizer.—[N J 24672 April 1936]

TeenJore Ointment—George Lee, Chicago. Composition Essentially ammoniated mercury, camphor and petrolatum. Fraudulently represented as a Famous Old Chinese Remedy for eczema, dandruff, ulcers, psoriasis, etc.—[N J 24677 April 1936]

Wilhelm's Salve—Dr. G. F. E. Wilhelm's Sons, Crafton (Pittsburgh), Pa. Composition Essentially lead compounds such as lead oleate and oxide, camphor, an extract of woody material such as elm bark and fat. For catarrh, carbuncles, soft corns, running sores, etc. Fraudulent therapeutic claims.—[N J 24671 April 1936]

Ferro China De Anghis—Chemical Industrial Co. Providence, R. I. Composition Essentially cinchona alkaloids, strychnine, iron and phosphorus compounds, sugar, aromatics, alcohol and water. For anemia, general debility, malaria, etc. Fraudulent therapeutic claims.—[N J 24672 April 1936]

Hall's Canker Medicine—S. A. Saxton, Salt Lake City. Composition A zinc salt and boric acid. Fraudulent therapeutic claims.—[N J 24678 April 1936]

Carbosalve—Aid All Co. Newark, N. J. Composition Essentially petrolatum with 0.33 per cent of carbolic acid. Fraudulently represented as an antiseptic healing salve for sores, wounds and infections.—[N J 24679 April 1936]

Gosewisch's Garlic Tablets—D. Gosewisch, Inc. and the Genuine Garlic Tablets Corp., New York. Composition Essentially sugar, corn starch, milk sugar and vegetable tissue having a garlic-like odor. For high blood pressure, arthritis, asthma, kidney disorders, diphtheria, tuberculosis, etc. Fraudulent therapeutic claims.—[N J 24682 April 1936]

Unguentine—Aid All Co. Newark, N. J. Composition Essentially petrolatum and paraffin with 2 per cent of carbolic acid. For ulcers, eczema, piles, etc. Fraudulent therapeutic claims.—[N J 24679 April 1936]

Capsicum Salve—Aid All Co. Newark, N. J. Composition Essentially petrolatum with 3.4 per cent of wintergreen and oleoresin of red pepper. For rheumatism, lumbago, etc. Fraudulent therapeutic claims.—[N J 24679 April 1936]

V. M. (VegeMucene) Tablets—Bio Vegetin Products, Inc. and V. M. Products, Chicago. Composition Essentially plant material including peanut hulls and seed coats, flax pods, stems and hulls, corn starch and mucilaginous material. Fraudulently represented as a treatment for stomach ulcers and inflammations, hemorrhages, etc.—[N J 24685 April 1936]

Blanchard's (Prof. Joseph) Eczema Lotion—Joseph Blanchard and Bauer & Black, Chicago. Composition Mercuric chloride, a small amount of borax, gum, alcohol and water. For ulcers, piles, psoriasis, eczema, etc. Fraudulent therapeutic claims.—[N J 24684 April 1936]

Baker's Cough Syrup—Baker Extract Co. Springfield, Mass. Composition Essentially extracts of plant drugs such as white pine, sassafras, wild cherry and tar with chloroform, alcohol, sugar and water. Fraudulent therapeutic claims.—[N J 24686 April 1936]

Ferond's Hair Grower and Tonic—Sherry, Inc. New York. Composition Essentially petrolatum, salicylic acid and a balsam such as balsam of Peru. Fraudulent therapeutic claims.—[N J 24688 April 1936]

Correspondence

SIGNIFICANCE OF POSITIVE WASSERMANN TEST IN NEW-BORN INFANT

To the Editor —In THE JOURNAL, September 25, Dr Charles Walter Clark reported a case supposedly of third generation syphilis. I believe his data fairly well establish congenital (prenatal) syphilis of the mother. However, the diagnosis of syphilis in the infant seems to be based entirely on positive, apparently nonquantitative serologic reports which are not sufficient evidence for the diagnosis. It has been conclusively demonstrated that an infant born of a syphilitic Wassermann-positive mother may have positive serologic signs at birth which gradually disappear, the child being normal clinically and eventually negative serologically without treatment (Dunham, E. C. The Diagnosis of Congenital Syphilis in the New-Born, *Am J Dis Child* 43:317 [Feb.] 1932; Faber, H. K., and Black, W. C. Quantitative Wassermann Tests in Diagnosis of Congenital Syphilis, *ibid* 51:1257 [June] 1936.)

The explanation for this lies in passive transplacental transfer of reagin from the blood of the mother to that of the fetus. The postpartum concentration of reagin in the infant's blood is sufficient to give a strongly positive reaction, the reagin content gradually falling off and eventually disappearing in those patients who are syphilis free. It cannot be too strongly emphasized that a positive cord or neonatal blood Wassermann or flocculation reaction is more of a reflection of the state of the maternal blood than of that of the infant (Fildes' law) and that a positive reaction does not necessarily signify syphilitic infection in the infant.

Successive quantitative tests determining the reagin titer of the infant's blood if revealing a rise (increased positivity), would have been, in the absence of clinical signs, a more reliable, if not the only reliable, means of establishing the diagnosis of syphilis in the infant. It is of interest to note that in the article by Faber and Black a case is presented (case 3) that might have been regarded as third generation syphilis had not quantitative tests for the reagin titer been carried out.

Allegheny General Hospital,
North Side, Pittsburgh

DIET AND NEPHRITIS

To the Editor —It seems unfortunate that the interesting experiments of Farr and Smadel on the influence of diet on rats suffering from experimentally produced nephritis should have been so emphasized in the editorial columns of THE JOURNAL (October 9, p. 1202) that the reader is given the impression that anything more than a very low protein diet may well prove disastrous for the human patient with nephritis. Aside from the possible differences between rats and men, the experiments as they stand if transferred to human patients, would lead to no such conclusion.

As the figures are quoted the diet lowest in protein, and on which the nephritic rats seemed to thrive consisted of salt mixture 4 per cent, protein 5 per cent, fat 27 per cent and carbohydrate 64 per cent plus adequate vitamins. For a man weighing 100 pounds (45 Kg.) one would have to give a diet of at least 3600 calories in order to supply the minimum nitrogen requirement. The arrangement quoted would be divided thus: protein 47.50 Gm., fat 108 Gm., carbohydrate 608 Gm.

Diet 2, which proved injurious to nephritic rats, if isocaloric and, divided as specified, would contain protein 18 per cent, fat 27 per cent and carbohydrate 51 per cent, or protein 155 Gm., fat 108 Gm. and carbohydrate 486 Gm.

Diet 3 which proved disastrous to nephritic rats with protein 40 per cent, fat 27 per cent and carbohydrate 29 per cent would

amount to protein 380 Gm., fat 108 Gm. and carbohydrate 275 Gm. Two pounds of roast beef contains this amount of protein.

Obviously not one of these diets is suitable for the human nephritic patient of 100 pounds weight. For the average sized man they would have to be increased by 50 per cent to be consistent. In view of the conception of nephritis as a debilitating disease with a special drain on the body proteins, as shown by Peters and his co-workers (*Arch Int Med* 37:153 [Feb.] 1926), McCann and Keutmann (*J Clin Investigation* 11:973 [Sept.] 1932), McLester (*THE JOURNAL*, July 16, 1932, p. 192) and others, the rational indication appears to involve a protein ration that is decidedly more than a normal minimal figure. My own experience has tended to confirm these considerations, and I believe that most other clinicians who have approached the problem from this standpoint have reached the same conclusion.

TASKER HOWARD, M.D., Brooklyn

CONTRAST BATHING FOR FEET

To the Editor —Dr Dudley J. Morton's article on the feet in THE JOURNAL, October 2, was of interest to me, particularly his description of contrast bathing.

For several years I relegated the buckets to the limbo of forgetfulness except in the occasional case in which running hot and cold water was not obtainable. The reasons for discarding the usual plan were as follows: 1. At times the size of the feet precluded simultaneous immersion in one bucket. 2. It was difficult to keep the water in the warm bucket warm and in the cold bucket cold.

The buckets were replaced by a hose attached to the common spigot of the bath tub by means of a water thief attachment. On the other end a sprinkler such as is used by barbers in rinsing the head after a shampoo was attached. The patient sat on the edge of the bath tub, adjusted the temperature of the water as to heat and sprayed the feet and legs for a period of a minute, then shut off the adjusted water and turned on the cold, spraying with this for a minute. The same number of times for each, five, that Dr. Morton suggests was used.

The results from this method have been much better than from the buckets: (1) because flowing water was used instead of static water, (2) the temperature could be kept at an even point and (3) the shock of the rapid change from warm to cold with a forced stream seemed to act much better than the immersion method in producing vascular reaction.

I have used this not only in the type of case referred to by Dr. Morton but also in circulatory disturbances and in subacute or chronic arthritis, in fact, whenever contrast baths have been indicated, this method has been used.

ARTHUR D. KURTZ, M.D., Philadelphia

CONSTITUTIONAL EFFECTS OF SALICYLIC ACID IN OINTMENT

To the Editor —A potentially interesting coincidence occurs in the October 2 issue of THE JOURNAL. On page 1142 there is a report by the Bureau of Investigation concerning a reducing compound, 'Poinpay,' which is being distributed by some of the largest and best known department stores in the country. According to the analysis of the American Medical Association Chemical Laboratory the preparation is essentially 66 per cent salicylic acid in petrolatum. The directions for its use recommend that the entire body, including the face, be covered with the ointment and that it be left on for a length of time that would amount to more than an hour. A single jar of the stuff contains enough for seven applications.

On page 1160 of the same issue appears an abstract of a paper by G. Sannicandro in *Dermosifilografia* in which he

describes the case of a boy of 7 years who was treated by the application of 5 per cent salicylic acid ointment to psoriatic lesions on the trunk, knees and elbows. The boy died forty hours after the application of the ointment and it was determined that death was due to poisoning from the passage of the acid into the body. He points out the fact that the therapeutic dose of salicylic acid in adults varies with the individual, according to the presence or absence of a congenital or acquired sensitivity.

ROY E. REED, M.D., Fayetteville, N. Y.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

ENDOCARDITIS

To the Editor—What is to be done in stubborn endocarditis? The cause of illness may be tooth infection of last summer and also overwork before final postgraduate examinations. The patient is a man aged 25. After an abscess and removal of the tooth it seemed to heal well in August. By the last of August the patient climbed some 1500 feet on Mount Ranier, came back the same day and felt fine. By mid-December overwork left him tired and weak, which only rest in bed would relieve. He relapsed and grew worse until almost a collapse February 10 with extreme nervousness and a systolic blowing murmur. The pulse was 108, the temperature was 100 and he was considered as having carried an elevation of temperature much longer than he knew. The metabolism then was —17 it had never been taken before. He improved soon when kept in bed but against advice in ten days he moved from the hospital and was somewhat upset again for several days. No spots at the capillary ends or enlargement of the spleen were noted. After twenty days in bed the temperature would usually go to 100 or 99 daily (morning, early, usually subnormal), the pulse getting down to about 90. During the next twenty days up to now the temperature would go to 99 or 99.1 once or twice daily on half of the days and a little less often the last ten days. The pulse began with 90 to 88 and is now usually from 78 to 82. About nine days ago he went five days without touching 99 twice and the pulse ranged between 78 and 84. The nervousness and restlessness had all left him. By tests and thorough examinations all signs of tuberculosis were lacking. Five different cultures were grown to find an organism but all were negative; however, they were grown for only five days. The test for undulant fever was negative. Some pain about the heart has dulled and is now there only part of the time. The patient sits up for meals and goes to the bathroom once a day. He has a good appetite and is in fairly good condition as he is taking A and D vitamin pills and hemoglobin aid once a day. Sleep is only fair. He is more worried now as improvement has seemed to be at a standstill the last few days. The early morning pulse seems very different from all others of the day; it is less full and at times either a hesitation or another beat is trying to appear. The blood pressure was 130/80 something but now is 126/78. As the young fellow is much discouraged an early answer will help immediately as I am not sure what to do next. Is there any use hunting again for an organism unless there is a serious relapse? Isn't five days short for the incubation period in a hunt for an organism? As nothing else seems to improve the condition is there any harm in trying prontosil or prontosil even if a streptococcus is not found though this is strongly suspected? If used, what is the dose and how is it managed? Where is it obtained? As there has been much nervousness and thrashing around of the arms and legs some evenings a few times I have used 1½ grains (0.1 Gm.) of phenobarbital. Is there any harm from reaction or to blood developing mechanism? The mucous membranes of the mouth and gums have seemed too brightly red to me since I have seen the patient (twenty-eight days ago) but the doctor once seeing him and the dentist insist that they are normal. Only one culture was made from the mouth and was negative. The gums have retreated quite a little since January. Should a more and better search be made again in the mouth? Could beginning pyorrhea or undiscovered Vincent's angina cause the endocarditis? Or may it be that the endocarditis alone now is causing 0.5 degree of fever half the day? By now the mucous membrane and gums are improved slightly.

M. D. Washington

ANSWER—First it should be stated that all endocarditis is stubborn. There is no royal road to recovery and the one therapeutic measure that all authorities agree on is prolonged rest in bed.

Secondly a diagnosis of endocarditis cannot be established on the information given. It may be strongly suspected but it cannot be proved and a search for other causes of long continued fever should be continued. To mention only a few of these causes an infectious mononucleosis should be ruled out by means of the blood picture and the heterophile antigen test. The picture suggests an acute rheumatic fever. Are the nervous manifestations suggestive of chorea? Have rheumatic nodes been sought for? Have any structural changes taken

place in the heart since the onset? The search for hidden tuberculosis should be continued.

To answer the specific questions, the organisms may be found in the blood at any time but they are most easily found at the height of the fever during a relapse. They may be recovered from the culture in a few days. Frequently they are not found until after ten days of incubation and they have been recovered after more than twenty-one days, hence five days is too short a period of incubation. Several brands of sulfanilamide have been accepted for inclusion in New and Nonofficial Remedies. Prontylin is the Winthrop Chemical Company's proprietary name for sulfanilamide (para-aminobenzenesulfonamide). Prontylin has not been accepted, since the firm has not met the requirements of the Council. Pron-tosil is a trade name which has been used for several substances. In the United States it generally refers to an azo dye of the para-aminobenzenesulfonamide group which is given by injection and has been used alone and in combination with sulfanilamide in the treatment of certain streptococcal infections. Its chemical formula indicates the possibility of certain undesirable results but so far only mild toxic manifestations have been reported as the result of its careful use in cases in which over-dosage and prolonged use have been avoided. The use of this material is still somewhat in the experimental state and the best results have been obtained from its use in hemolytic streptococcus infections. It seems unlikely that the present case is of such origin.

There can be no objection to the moderate use of phenobarbital.

As a general rule it is unwise to stir up local foci of infection during an acute exacerbation. Such manipulation unquestionably throws an additional load on the patient and not infrequently he is unable to cope with the reaction. Unless such a focus is actively causing trouble of itself, a conservative policy is to be preferred.

It would seem that the plan of rest plus symptomatic and supportive treatment should be carried on in this case. Any specific drug or other treatment should be held in abeyance until some definite reason can be found for the use of such agents. The patient should be persuaded that these chronic infections heal slowly and that several months now may not only save his life but also determine whether he shall be healthy or an invalid in the future.

ETIOLOGY AND TREATMENT OF ABORTION

To the Editor—1 Will not the intake of drastic cathartics, ergot and quinine and mustard foot baths induce an abortion in a woman three weeks past her expected period? 2 Would not the intake of large amounts of oxytocics and emmenagogues together with an associated laceration and erosion of the cervix predispose the uterus to infection? 3 Assuming that an instrument was introduced within a pregnant woman and infection took place, how soon or late would fever become manifest? 4 How would or should a doctor distinguish between a sapremic fever and the fever in the early stages of sepsis? 5 What are the other causes of a septic abortion besides the insertion of an instrument into the uterus? 6 Can a doctor truthfully state for how long a lacerated cervix has existed only by inspection? 7 In a pregnant woman complaining of an excessive and annoying leukorrhea would a doctor be justified in treating the cervical laceration and erosion? You can rest assured your answers will clarify many points.

L. ALEXIS SAGNELLA, M.D., West Haven, Conn.

ANSWER—1 The use of drastic cathartics, ergot, quinine and mustard foot baths will seldom induce an abortion at any time. If the reverse were true the abortionists would have very little business.

2 No.

3 Usually within three or four days but rarely later than ten days.

4 Ordinarily the term sapremia is limited to those infections in which only putrefactive organisms are present. Likewise the term sepsis or septicemia is usually used to mean the presence of bacteria in the blood stream. In sapremia the symptoms are due to the absorption of toxins from decomposing matter in the genital tract. If a piece of placenta or membrane is still attached to the uterine wall the patient will usually have uterine cramps which will persist until the secundines have been removed mechanically or more commonly expelled spontaneously or after the use of oxytocics. Usually the fever subsides after such tissue has been expelled. As long as secundines remain in the uterus the discharge is profuse and generally very bloody. Not infrequently there are repeated hemorrhages from the uterus or large blood clots are passed. The uterus is definitely enlarged, soft and tender. It is safer to determine this by rectal examination than by vaginal exploration. If a vaginal examination is made great gentleness must be exercised and of course aseptic and antiseptic precautions must be taken. Not infrequently a piece of tissue is seen pro-

truding through the external os. Occasionally such tissue blocks the cervix and produces leucorrhoea. When sepsis is suspected, a positive blood culture will clinch the diagnosis. In most cases the responsible organism is the streptococcus but other organisms may cause sepsis. These bacteria may gain access to the blood either through the blood vessels or through the lymphatics, and the symptoms that result may vary according to the route of the infection. Generally symptoms arise from one to three days after labor. Often the illness first manifests itself by a severe chill, high temperature and rapid pulse, and the patient rapidly gives evidence of being critically ill. The symptoms that appear are pallor due to anemia, severe headache, nausea, vomiting, persistent fever, infection of the puerperal wounds and signs of peritonitis.

5 The insertion of jellies, solutions, laminaria tents, and a large number of home-made instruments such as pencils, ice picks and umbrella ribs

6 No

7 It is first necessary to determine the cause of the discharge. If the latter is due to *Trichomonas vaginalis* or to *Monilia*, this discharge can generally be cleared up by treatment of the vagina alone. If the discharge is not due to a specific organism and appears to come from the cervix, the latter may be treated, but with great gentleness. It is best, however, to have the patient remove the leucorrhoea mechanically by using low-pressure vaginal douches of plain water or water containing sodium bicarbonate or table salt and defer treating the cervix until after delivery.

NEURODERMATITIS

To the Editor—A woman aged 22 has been suffering from an unbearable itching sensation of the skin for the last three years. It started while she was in training school and in a rather run-down condition, with a series of boils some of which had to be incised. The itching areas involved only the forearms and the cubital fossae and the skin appeared normal. Gradually it spread over the upper half of the body. For the last three months the itch has extended to the lower extremities. She cannot sleep and passes whole nights scratching. The skin is dry and thick and shows lesions which most likely are secondary scratch effects and not a primary skin disease. The patient has been seen by a number of specialists and has been through most of the routine dermatologic treatments. Complete urine and blood examinations were entirely negative. Allergy tests did not reveal anything. The patient is of a nervous type with dysmenorrhea (irregularly cramping pains and virgo). She had frequent edema of the eyelids and face before the itch came on. She sneezes often without having any signs of a head cold. During the three years of sickness she has had one short interval when she felt perfectly normal. That was the time she quit training school for two months and lived at home. As soon as she returned to school the itch reappeared. She had to drop training completely and has had no itch-free time since. Thank you very much for any suggestions you may be able to offer.

ERNEST FREUND M.D., Venice, Fla.

ANSWER—The description fits what is commonly called generalized neurodermatitis. While there is no doubt a large nervous factor, no effort should be spared to discover other factors, for they complicate many cases of this kind. The sudden recovery when the patient came home from training school suggests a contact dermatitis, although other features do not agree. This possibility, if not already worked out by patch tests, should be again investigated. The furunculosis preceding the pruritus suggests the possibility of a sensitization to pus organisms, but this should have been discovered by the tests already made. Frequent sneezing brings to mind the report of silk dermatitis not due to contact of silk with the skin but resulting from inhalation of silk dust when clothing of this material is worn. Patch tests were negative. Silk dust in the nose brought on the dermatitis. Other inhalants may be guilty (Figley, K. D., and Parkhurst, H. J. *Silk Sensitivity with Special Reference to its Role in Atopic Eczema*, *J. Allergy* 5: 60 [Nov.] 1933).

The dysmenorrhea brings up the possibility of an endocrine disturbance at the basis of the nervous condition. If not already tried without success, gonadotropic substance should be administered. Even though the endocrine factor is not an important one, relief of this distress will contribute to the comfort of the patient, lessen her nervousness and increase her resistance.

Continued watchful blood examinations at regular intervals are indicated as long as the dermatitis lasts, to discover a possible lymphoblastoma of which the itching is the only present sign. The external and internal lymph nodes should also be watched for signs of Hodgkin's disease. A biopsy of the skin in the most infiltrated part might suggest one of the lymphoblastomas before other signs appear, but the incipient dermatitis of these diseases seldom shows a typical histologic picture.

Liver function tests and an investigation of the bile tract may reveal an etiologic factor. Even though no lesion or

functional disturbance of the gastro intestinal tract can be discovered by tests, it is possible that intestinal conditions may be responsible, and it is justifiable to try colonic washings after simpler measures have failed.

Finally, a wise neurologist may discover a mental factor that can be treated.

Aside from treatment of the cause, the management should be in every possible way soothing. Colloid baths should be tried composed of three cupfuls of bran or oatmeal boiled in a gauze bag in two quarts of water to make a porridge. The bag and the water in which it has been boiled are then put into a half tubful of warm water and stirred about and squeezed gently. Less troublesome is the use of starch which can be put directly into the bath water. If it is desired to combine the alkaline bath with the colloid bath from 60 to 300 Gm of sodium bicarbonate or borax may be put into the bath water and well dissolved before adding the colloid material. The water should be kept at 98 F. and the body covered with water or with warm moist bath towels and drafts avoided. If well borne, such baths may be lengthened and repeated several times a day until continuous or almost so. On removal from the bath, the skin should be partly dried by dabbing and an ointment or oil applied with as little rubbing as possible. Olive oil, olive oil and glycerin rose water ointment with or without 10 per cent boric acid equal parts of rose water ointment and wool fat or other fat combinations should be tried to find the one most agreeable to the patient.

Phenol up to 1 per cent and menthol about 0.25 per cent act beneficially not only by direct soothing but also by giving the patient something to do instead of scratching. Sulfur and various tar preparations can be tried cautiously on a small area to test their safety and efficiency before using them extensively. Many neurodermatitis patients are more comfortable on pastes or powders than on greasy preparations in spite of the dryness of their skins.

General soothing can be aided by the use of bromides or one of the barbiturates. The fear of dermatitis medicamentosa need not hinder their use, for it is not very common. It should be watched for, as well as the undesired effects on the nervous system. Diathermy, gently used, has been known to exert a distinctly soothing effect. General ultraviolet exposures below the erythema dose have a soothing effect in many cases. Foreign protein treatment may be beneficial. Autoblood intramuscular injections or autoserum intramuscularly or intravenously are as mild as any. Milk injections may be tried. The possibility of sensitization must always be kept in mind, and these methods tried with great caution.

BENTONITE DUST

To the Editor—There are extensive deposits of bentonite in this locality. Many men are employed in the industry which requires work in the dust during the process of grinding and sacking in preparation for shipping. I have roentgenographed a number of the employees of the American Colloidal Company. I find evidence of deposits in the lungs especially the lower lobes. Will there be any effect on the health of these men in later years? Some of the men have been employed in the industry for from five to ten years and seem to show no effects from inhaling the dust.

J. L. CHASSELL M.D., Belle Fourche, S.D.

ANSWER—Bentonite is a nonrefractory colloidal clay, probably formed from volcanic rock. It represents a mixture of silicates, and some specimens probably contain free silica although not necessarily in the form of quartz. Recently McCord and his associates (McCord, C. P., Fleming, R. L., Anslee, Harriet, and Johnston, Jan. *Surg., Gynec. & Obst.* 63: 129 [Aug.] 1936) published the results of a series of animal experiments in which divers minerals, including bentonite, were introduced into the abdominal cavity. Bentonite led to atypical results, not characteristic of any of the reactions described by Miller and Sayers. Certain dusts produce a proliferative response which is characteristic of silica, others an inert response typified by iron oxide and still others are absorbed as is true for calcite, for example. Bentonite yielded results described as "mixed." On appropriate microscopic examination a few characteristic proliferative lesions were established in the midst of a preponderance of inert reaction. On this account it is possible that bentonite may be more active than the ordinary silicates in bringing about changes in the lungs.

No dust taken into the lungs over long periods and in appreciable quantities is entirely innocuous, but apart from silica, which, as is stated above, is a constituent of bentonite and asbestos the changes induced rarely exceed a state other than that termed "more fibrous than usual."

Since it appears that no great amount of investigative work has been directed to the properties of bentonite as a source of dusty lung disease in industrial workers it is desirable to hold in abeyance any final opinion pending further experience.

ANGIONEUROSIS WITH ACROPAESTHESIA

To the Editor—A man, aged 35, a dye worker for the past fifteen years came to me complaining of throbbing pains in the popliteal region and some pain in the left knee cap arch of the left foot and the left heel and of his second and third toes which fell asleep at times. Of late he has also felt some soreness of the adductor muscles of the left thigh. As a rule it is one of these complaints or another but they seldom occur simultaneously. His trouble began suddenly about seven years ago with pain in both feet which he experienced on arising one morning. Prior to this the patient had been taking salts to reduce weight and had had the grip at about the same time. He consulted a good orthopedic surgeon at this time the latter ordering arch supports after a series of x-ray examinations and consultations with another good physician. The roentgenograms according to the patient were entirely negative. For six months after wearing his arch supporters he was practically free from pain but became worse soon after this which necessitated removal of these supporters with the result that he felt better. A few months later, however, his trouble localized itself to the left knee and left heel. The right leg is entirely free from any discomfort at the present time. He has again tried arch supporters but the condition is aggravated. He has been to other physicians and no one can seem to do anything for him. Of late most of his trouble seems to be in the popliteal region although there seems to be some discomfort in the form of aching pains above the knee cap and heel. He cannot sleep unless his left leg is abducted and semi flexed. At times he feels the blood vessel behind his left knee throbbing and heating very fast but there is no pain as a rule at this time. These symptoms are intermittent worse and more frequent on lying or standing when the leg is extended. The past history is negative. The patient has always been perfect and still feels so except for his left leg. There is no history of gonorrhea or syphilis. As far as the physical examination is concerned, there is nothing very significant. The Kahn reaction and urinalysis are negative. Knee jerks and other reflexes are slightly hyperactive but equal. There are no areas of tenderness except when palpating deeply into the popliteal space. Thus far I have not been able to make out such a thing as popliteal aneurysm. Pulsation of the artery of the dorsum of the left foot is questionable. There are no areas of anesthesia or hyperesthesia. The patient perspires very easily. The blood pressure is 140 systolic 70 diastolic, the pulse rate 80 to the minute. Could this be solely a vascular condition? Could a neuromuscular condition cause this trouble? Do you think the patient's occupation has any relation to this condition? Diathermy has diminished the pain to some extent. Is this contraindicated?

EDWARD A. RICCI MD Providence R I

ANSWER—The lesions to be considered are vertebral arthritis, spinal cord tumor and lesions involving the second to the fifth lumbar and first to third sacral vertebrae. The entire pathologic syndrome could be on a vascular basis. There may be a neuromuscular lesion. This condition would be classified as angioneurosis with acroparesthesia. There may be embolism or thrombosis, bursitis in the popliteal region or varix. The patient's occupation undoubtedly has some relation as a predisposing factor. Static balance of the feet and legs is important. The urine should be examined for the presence of lead. Diathermy is contraindicated until a positive diagnosis can be made. Oblique x-ray projections should be made to visualize the intervertebral articular facets. Roentgenograms should be made to determine arteriosclerosis. The histamine test should be considered, and so should sodium iodide injection followed by fluoroscopy.

EFFECT OF HORMONES ON PITUITARY AND DIABETES MELLITUS

To the Editor—Please print any information about drugs and gland extracts that might have an inhibitory effect on the anterior pituitary hormone and also the course of diabetes mellitus.

G E LOWREY MD Harrodsburg Ky

ANSWER—That the anterior lobe of the pituitary is concerned with carbohydrate metabolism is definitely established but its role in human diabetes mellitus remains an open question. It is true that the diabetes in depancreatized animals is alleviated by removal of the pituitary gland but when an attempt is made to suppress the activity of the anterior lobe by other means and thereby alter the severity of the diabetic state either in the experimental animals or in human diabetes there are conflicting results. Barnes, Regan and Nelson (1933) were able to diminish the glycosuria in depancreatized dogs by injecting estrogenic substance and attributed their success to suppression of the pituitary gland. Nelson and Overholser (1934) confirmed their studies and found that the diabetic blood sugar in pancreatectomized rhesus monkeys was lowered after estrogenic substance was given. They concluded that the estrogenic substance depresses the diabetogenic hormone of the anterior pituitary, although it (estriol) was without effect in one instance.

Jones and MacGregor (*Lancet* 2 974 [Oct 24] 1936) were able to inhibit the gonadotropic principle of the anterior pituitary by giving large doses of estrogen to ten psychotic women past the menopause but found no consistent effect on the dextrose tolerance test. They concluded that inhibition of the anterior pituitary was not accompanied by inhibition of the diabetogenic principle.

Wilder and Wilbur, in their latest review (*Arch Int Med* 59 329 [Feb] 1937) of recent contributions to diseases of metabolism and nutrition state that Mazer, Meranze and Israel and Houssay have observed alleviation of symptoms of diabetes mellitus in some instances after injections of estrogen but that Collens and his associates could not confirm this. Wilder discusses in detail Himsworth's observations on patients with diabetes mellitus placed on diets high in carbohydrate and notes the suggestion that diets rich in carbohydrate lower the activity of the hypophysis.

There is no adequate evidence that the administration of any substance known to be capable of depressing at least one function of the pituitary has any favorable effect on human diabetes mellitus.

CONGENITAL DISLOCATION OF HIP

To the Editor—I have under my observation an infant of 4 months in whom I suspect but am not certain of the diagnosis of congenital dislocation of the hip. Because a cousin of the infant has a congenital dislocation the parents have been on the alert for any similar symptoms in their child and first noticed that there is a marked crease on the medial side of the thigh. I cannot see that there is any difference in the gluteal creases posteriorly or any difference in palpation of the femur nor is there any difference in the use of the two thighs. In the x-ray plate one could not say that the suspected side was definitely higher than the other side but perhaps it is a trifle. The only definite thing is this marked crease on the medial side of the thigh together with a family history for it. Is it not quite possible that the child might have a dislocation and that any obvious displacement might not manifest itself until the child commenced bearing weight on the leg? Could this be true to such an extent that the x-ray plate at this age might not show any real displacement? What other signs should be looked for in an infant that does not walk which would help to clarify the diagnosis? At what age should treatment be started? What is the correct treatment?

M D, North Dakota

ANSWER—It is quite possible that the patient may have a congenital dislocation of the hip. Early diagnosis of congenital dislocation of the hip can be made. (1) The leg on the side of the dislocation may not be moved so freely as the other, (2) there may be moderate resistance on attempting complete extension, (3) the inguinal and also the gluteal folds of the affected hip may be higher than those of the other side, (4) when the thigh is flexed to right angles with the body abduction may be resisted on the affected side, (5) if the condition is bilateral there may be widening of the perineum. A roentgenologic examination will show a poorly developed acetabulum, but in the young infant there will not be definite displacement of the femoral head. The epiphyseal center of the head may be irregularly ovoid, while the ossification center of the normal epiphysis is round. These changes are so slight that the roentgenologist may be unwilling to consider them abnormal.

In the child in whom the condition is recognized in early infancy, it is usually possible to effect a cure by simply applying an abduction splint of a type described by Putti (*Congenital Dislocation of Hip, J Bone & Joint Surg* 11 798 [Oct] 1929) and used in this country by a number of orthopedic surgeons. There is also a simple and apparently equally effective apparatus described by Chapple (*Congenital Dislocation of the Hip in Infancy, J Pediat* 6 306 [March] 1935). This splinting should be continued for twelve months.

If treatment is delayed until the child is more than 2 years of age, continuous casts, repeated closed reductions and, in about 20 per cent of the cases, open reduction may be necessary. The older the child when treatment is begun, the greater is the danger of serious permanent disability. The need for early diagnosis and early treatment cannot be overemphasized.

LACK OF FREE HYDROCHLORIC ACID IN GASTRIC CONTENTS

To the Editor—1 What diseases other than pernicious anemia, carcinoma and achylia show a persistent lack of free hydrochloric acid in the gastric analysis? 2 Is the lack of free hydrochloric acid compatible with good health aside from minor intestinal disturbances? 3 Please refer me to literature.

M D California

ANSWER—1 Acid secretion and ferment secretion are two distinct results of gastric glandular secretion and are independent of each other. Achylia gastrica implies a complete absence of both secretions. Achlorhydria, or lack of hydrochloric acid, is relatively frequent as compared to achylia. Achlorhydria may be found in acute and chronic gastritis, secondary to chronic appendicitis, cholecystitis or pancreatitis, in severe secondary anemias and in severe wasting disease. It may arise as a result of acute depressed mental conditions and sudden nervous shocks. It may be diminished or offset prior

to each menstrual period. It may be present as a congenital condition. The condition may give rise to no symptoms or only those of the primary disease may be manifested. Gastric symptoms are present in about 3 per cent of the cases, such as anorexia, fullness in the stomach, eructations, and at times heart burn. Intestinal symptoms are more frequent and present in approximately 34 per cent of cases, most commonly diarrhea and less frequently flatulence and intestinal toxemia.

2 Yes

LOSS OF WEIGHT DURING PREGNANCY

To the Editor—Will you please discuss the probable causes of loss of weight in the case described? A primipara aged 24 apparently in good health married five years had her last menstrual period Dec. 16, 1935. The estimated date of confinement is Sept. 24, 1936. The past history is unimportant except for hyperthyroidism four and a half years ago from which she states that she recovered with good health for in the past four years her lowest weight has been 104 pounds (47 Kg.), her best weight 118 pounds (53.5 Kg.) before pregnancy. May 11 the fifth month of pregnancy her weight was 116½ pounds (52.9 Kg.) no gain in weight. June 11½ pounds (52.8 Kg.) July 116 pounds (52.6 Kg.) August 116 pounds (52.6 Kg.) September 13 118½ pounds (53.7 Kg.) September 24 the day of delivery of a healthy infant weighing 6 pounds (2.7 Kg.) her weight was 114 pounds (51.7 Kg.) a loss of 2½ pounds (1.2 Kg.) the last four months of pregnancy. The total amount of amniotic fluid at delivery was approximately 6 ounces (178 cc.). The patient remained apparently in good health throughout pregnancy and showed none of the usual signs of a return of the hyperthyroidism. Please omit name.

M. D. Maryland

ANSWER—It is unfortunate that the patient was not subjected to at least one basal metabolism study during the latter months of pregnancy, because a marked increase in the basal metabolic rate might have explained the weight loss. However, a high basal rate during pregnancy is by no means always associated with a loss in body weight. Strenuous dieting during pregnancy can account for a loss of weight even in the presence of a baby of normal or above normal weight at birth. In the absence of definite hyperthyroidism and deliberate restriction of carbohydrates and fats, it is difficult to account for the loss of weight. Some disturbance in the glands of internal secretion may be at fault but what this is cannot be decided. An actual loss of weight during the latter months of pregnancy is most unusual hence an adequate study of such cases has not been made.

USE OF ANTHELMINTICS DURING PREGNANCY

To the Editor—A well nourished woman aged 30 two months in her second pregnancy has taenia saginata. There are no symptoms except increased appetite. She has noticed the worm segments being passed at stool during the last two or three months. Is it advisable to wait until pregnancy has terminated before giving treatment? If not what is the most desirable method of treatment in this case?

V. L. HAWES, M.D., Ramsey, N. J.

ANSWER—In the absence of any symptoms attributable to *Taenia saginata* infestation it is advisable to wait until after labor has been terminated to administer anthelmintic treatment. Solomon Solis-Cohen in discussing the oleoresin of aspidium, lists pregnancy as a contraindication to its use.

On the other hand Leon Moise (*Ann. fac. franç. de med. et de pharm. de Beyrouth* 3: 183 [May] 1934) comes to the conclusion that it is advantageous to treat all pregnant women who show signs of infestation. He reports a case of *Taenia saginata* infestation in pregnancy which in the ninth month, showed signs and symptoms simulating the preeclamptic state. Anthelmintic treatment was followed by prompt alleviation of symptoms and the disappearance of albumin from the urine. Another case of tachycardia in the puerperium was relieved by the spontaneous elimination of the parasite. To support this assertion further he cites J. Guart's contention that secondary infection is much more likely with the breaking down of the epithelial barrier in the intestine and the passing into the blood stream of *B. coli*. Joyaux believes that the presence of

Taenia saginata may interfere with pregnancy and cause abortion and that the absorbed toxins may be secreted in the milk of the mother.

If symptoms should appear, treatment in a hospital would be desirable. The anthelmintic of choice (Betha O. W. Tenauges, *Internat. M. Digest* 24: 47 [Jan.] 1934) is oleoresin of aspidium (male fern). The period of preparation should be longer, the bowels being gently evacuated and no drastic purgatives to be employed. It would perhaps be wise to use the minimum dosage and certainly not exceed 10 Gm. The usual precautionary measures to prevent absorption of the drug must be exercised. If the patient is treated after delivery, nursing is temporarily suspended.

CHANGING SEX IN GOATS

To the Editor—In the September 16 issue of the Indianapolis Star I noticed an article which with two pictures to demonstrate its authenticity stated: At the top picture is Billy a pet goat on the farm of Fred Jordan in Greene County whose sex life is a cause of much comment because he changed from a male to a female quite without warning or explanation. Having proved his masculinity by being the father of three kids by a nanny goat Billy later confounded his owner by developing an udder and giving milk—one quart a day. Below is an under view of Billy which shows him (or her) in action as a female of the species by giving down a copious stream of milk. There is no doubt regarding the authenticity of the article as numerous people have viewed the goat in question. As this is a very interesting condition I should like a scientific explanation as to how it could take place. 1 Since this animal has only male external organs and has been able to fertilize the female would this be a case of unilateral hermaphroditism? 2 Since lactation has taken place in this animal will it change his male characteristics in the future or will his future actions be the same as before lactation took place? 3 Is it ever possible for human beings without female gonads to lactate? 4 Do females ever have lactation without pregnancy?

M. D. Indiana

ANSWER—Sex is usually determined predominantly as male or female. However, double sex potentialities in vertebrates is always exhibited to some degree in that each embryo (including the human species) develops at first a gonad of common pattern which will develop into male or female under proper conditions. Each embryo also develops both male sex ducts (wolffian ducts) and female sex ducts (müllerian ducts). Usually the gonad develops positively into a testicle or ovary and the duct system into the appropriate male or female type. In goats particularly various grades of hermaphroditism are quite common and mixtures of all types of gonads and ducts have been recorded. The hermaphroditic condition may be visible externally at birth or may express itself only in later development. One sex can predominate, or organs of the two sexes (gonads and ducts) may be present in approximately equal amount. In extreme cases of intermixture it is more usual that the animal is incapable of acting as a male or female parent, though evidences of endocrine secretion of both male and female type may be apparent. The animal in question would appear to approach male normality with only moderate female development expressed by mammary growth and lactation.

1 It may be either a unilateral or a bilateral hermaphrodite with late expression of ovarian function.

2 It probably will not change.

3 There must be a source of female hormone sufficient to stimulate mammary development. Normal male guinea pigs injected daily with theelin will grow large mammary gland which will lactate when the injections are stopped at the end of a few weeks. The young may be nourished by these male secretions, provided the male is forcibly restrained, lactating males do not develop a female psyche.

4 Yes, but not usually. Endocrine disturbances are of many grades and in pathologic cases (usually certain types of tumors) men have experienced mammary hypertrophy and lactation.

SHELL'S KIEFZIT

To the Editor—Please inform me whether there could be any ill effects or toxemia for a pet or working in a room poorly ventilated and lit by Shell's Kieffzit.

HARRY M. COVELL, M.D., Auburn, Me.

ANSWER—This substance is reported to be manufactured by the Shell Petroleum Corporation and to represent a mixture of petroleum distillates with carbon tetrachloride. The latter presumably is introduced for the purpose of diminishing the fire hazard and for increasing solvent action. The percentage of carbon tetrachloride present is unknown.

As carbon tetrachloride is highly toxic and petroleum distillates are injurious to some extent the prospect of injury to a worker is related to the extent of evaporation and the duration of exposure. In case workmen are exposed to early

tetrachloride in concentrations above 100 parts per million, some or all of the following manifestations may arise: headache, nausea, vomiting, diarrhea, respiratory tract discomfort, pain and tenderness in the liver region, gastro enteritis and jaundice. These symptoms may, in more severe involvements, extend to others centering about renal injury. These include oliguria, possibly complete suppressed urine, nephritis, and so on. In mild cases irritation to the eyes, nose and throat and mental dulness may be the sole manifestations. Rarely blindness may be produced from the action of carbon tetrachloride. Chemical dermatitis from carbon tetrachloride is common. It is possible that the severe forms of acute carbon tetrachloride poisoning result from the presence of guanidine in the body, resulting from dysfunction of the liver induced by the action of carbon tetrachloride.

BEHAVIOR AFTER OPERATION FOR FRACTURE OF SKULL

To the Editor—Will you kindly give me information on the subsequent behavior and life history of individuals who have been operated on or have had fracture of the skull. Do they as a rule retain their usual intelligence and normal behavior? Do they develop any uniform type of misbehavior? What form does it commonly follow? Are there statistics available on this subject? Can you refer me to any records or books?

M D Pennsylvania

ANSWER—As to the subsequent behavior and life history of those who have had fracture of the skull or operations on the head and brain, it cannot be said that any uniform type of misbehavior is likely to occur. Possible permanent effects of head injury or brain operations are of course, dependent on the extent and location of the operation or injury. Most published studies on head injury have been concerned essentially with physical changes giving little consideration to changes in behavior. Glaser and Shafer (*THE JOURNAL*, Jan 23, 1932, p 271) and Wortis and Kennedy (*Surg, Gynec & Obst* 55 365 [Sept] 1932) give statistics. As to mental sequelae the most commonly described complex is headache, dizziness, irritability, insomnia, physical and mental fatigability, a change in character, intolerance to alcohol, and maybe an associated defect in memory. It must also be recognized that head trauma may be only contributory to the development of behavior changes, for example as in cases in which dementia paralytica becomes manifest after such trauma or an underlying neurosis or personality disorder is thus brought to the fore. The classic contribution of Adolf Meyer (*Am J Insan* 60 373 [Jan] 1904) should be consulted, or the summary of this paper given in *Diseases of the Nervous System* by White and Jelliffe. Other papers that might be consulted are to be found in the *Psychiatric Quarterly* July 1936, *American Journal of Psychiatry* 91, 1934 (two papers), the *Journal of Nervous and Mental Disease*, 1933, and the *Archives of Neurology and Psychiatry*, 1934.

SOURCES AND STABILITY OF VITAMIN A

To the Editor—What are the commercial sources of vitamin A? Will heat destroy all kinds of vitamin A (from different sources such as fish oil and carrots)? Is the rate of deterioration from air exposure well known?

CARLETON DEEDERER M D Miami Fla

ANSWER—There are a number of commercially available preparations which either contain vitamin A or have a vitamin A effect. New and Nonofficial Remedies lists carotene (a mixture of the isomeric forms of this hydrocarbon which functions as provitamin A), cod liver oil and other fish liver oils (which contain vitamin D as well as vitamin A). There also are a number of concentrates of fish liver oils. It is advisable to use only those preparations which stand accepted by the Council on Pharmacy and Chemistry. The potency of the products is declared in U S P units on the label.

Of course, the usual sources of vitamin A for the vast majority of people are foods, particularly animal foods such as butter and liver, vegetable products which are yellow, such as yams, yellow corn and carrots, and some green plants in which the chlorophyll masks the yellow provitamin A, such as spinach, escarole, lettuce and turnip and dandelion greens.

Heat in the presence of oxygen will destroy all varieties of vitamin A including the three isomeric carotenes, kryptoxanthine and vitamin A itself. The rate of deterioration of vitamin A from exposure to the air is variable. Solutions of crystalline carotene in oil lose their orange color and their vitamin A potency within a few weeks but the loss in potency of the vitamin A of fish liver oils is much less rapid. Certain substances retard the rate of destruction of vitamin A. Generally speaking it is well to keep preparations containing vitamin A in the cold and in the dark.

ALLEGED INTERFEROMETRIC EXAMINATIONS OF BLOOD FOR HORMONES

To the Editor—A woman presented me with a written statement by another physician as follows: Interferometric blood examination showed deficiency in ovarian thyroid and adrenal secretion and a hypersecretion of the anterior lobe of the pituitary gland. In addition to this the various glands were itemized as follows: ovarian 34 test 9 pit ant 26 pit post 10 thyroid 37 parathy 12 adr 17 pin 5 thymus 4. Will you please inform me as to what this interferometric blood test is? I am particularly interested in knowing how one may test the function of the pineal and thymus glands in any one and most curious as to how one may test the testicular function in a woman. Any information you may give me will be appreciated.

M D New York

ANSWER—The interferometer is a device used by physicists to measure dispersion of light and by no stretch of imagination could it be used to estimate the hormone content of the blood. The 'interferometric blood examination' reported above is sheer nonsense or worse.

The recognition of certain hormones by spectroscopic examination seems to be within reach, but so far this method has been confined to the recognition of pure substances. There is no authentic report in which the spectroscopic method has identified hormones in the circulating blood.

It is obviously impossible to estimate the testicular function in a woman, although androsterone may be isolated from female urine.

Little is known of the function of the thymus. Attempting to test this function is to test an unknown quantity. Any consideration of the pineal gland is unadulterated speculation.

X-RAY TREATMENT AFTER REMOVAL OF TUMOR

To the Editor—A white man, aged 60 presented himself with a skin ulcer located on the abdominal wall about half an inch below the navel. Originally the lesion was a strawberry tumor as the patient called it which broke down two years ago into a creeping bleeding ulcer about 2 inches long by 1 inch wide. Excision of a large section of the abdominal wall including the navel and down to the rectus muscles did not dis close any axillary adenopathy. The laboratory report was basal cell carcinoma. Is surgery sufficient or would you advise x-ray therapy as being necessary?

M D New York

ANSWER—Opinions differ as to the value of x-ray therapy after surgical removal of malignant tumors. With a basal cell carcinoma on the abdominal wall of the size mentioned, if removed widely x-ray therapy may be unnecessary. If definite metastases cannot be removed they might be treated by x-rays if a therapist is available with lots of experience and one who would be sure to give killing rather than stimulating doses. Some tumors seem to be stimulated to more rapid growth after small doses of x-rays.

CORRECT CYLINDER FOR DISTANCE VISION

To the Editor—I know that the minus cylinder is at a right angle or 90 degrees from where the plus cylinder should be. On changing the lenses in these cases to a plus from a minus I have been having difficulty in getting the patients to believe that the plus cylinder is the right one because as they say things are not as distinct and sharply outlined as before. What if any trouble could arise from this incorrect wearing of minus cylinders in place of the correct plus cylinders? Please understand that I am not speaking of simple myopic astigmatism. Please omit name.

M D Ohio

ANSWER—A plus cylinder often blurs distance vision even when it is the correct glass for correction of the error of refraction when the eye is tested under a cycloplegic. This is due to the fact that after the cycloplegic effect has "worn off" the ciliary muscle contracts and renders the lens more convex, the glass does the same thing, so that there is a doubled effect, the image is in front of the retina and vision blurred.

No great harm can come to the eye from wearing a weak concave cylinder under these circumstances although it is not theoretically correct, it often has to be done to get good distance vision.

CAN THE SEX OF CHICKS BE CHANGED?

To the Editor—A patient in the chicken hatchery business has asked me whether there is any information available about the use of endocrine products for the purpose of making all chicks female. If you can name any literature that would be useful I would appreciate it.

F A McMURRAY M D Vashon Wash

ANSWER—Hormone preparations have been injected into the developing egg with considerable modification of the sex glands and ducts in the developing chick examined a day or two before hatching. Thus far these experiments have not been carried to the point at which information is available with regard to the conditions of chicks hatched after such treatment. Injection into young and adult males does induce female feathers on males but does not change the sex glands into ovaries.

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL November 6 page 1568

California June-July Examination at San Francisco

Dr. Charles B. Pinkham, secretary, California State Board of Medical Examiners reports the written examination held at San Francisco June 29-July 1, 1937. The examination covered 9 subjects and included 90 questions. An average of 75 per cent was required to pass. One hundred and fifty-four candidates were examined, 144 of whom passed and ten failed. The following schools were represented:

School	PASSED	Year Grad	Per Cent
University of Arkansas School of Medicine	(1936)		82.2
87.4 (1937) 75.6 84.7			
College of Medical Evangelists	(1936) 80.2	(1937)	76.7
79.6 80.1 80.1 81.7 82.2 82.6 83.2 84.7 86.6			
Stanford University School of Medicine	(1937)		76.3

California July Examination at Los Angeles

Dr. Charles B. Pinkham, secretary, California State Board of Medical Examiners, reports the written examination held at Los Angeles, July 20-22, 1937. The examination covered 9 subjects and included 90 questions. An average of 75 per cent was required to pass. One hundred and twenty-nine candidates were examined, 115 of whom passed and 14 failed. The following schools were represented:

Book Notices

Bacteriology A Text Book of Micro organisms By Fred Wilbur Tanner Professor of Bacteriology and Head of the Department University of Illinois Urbana Third edition Cloth Price \$3 50 Pp 510 with 146 illustrations New York John Wiley & Sons Inc London Chapman & Hall Limited 1937

The author intended this book to be an introduction to the science of microbiology. He decries the custom of taking students too deeply into pathogenic bacteriology in their first course. He therefore stresses nonpathogenic as well as pathogenic micro-organisms. He believes that the constant tendency is to slight the classification of bacteria and to overemphasize the disease-producing micro organisms. The unsatisfactory condition of the classification of micro organisms may be partly due, he says, to the reticence of instructors to discuss such questions. In accordance with this idea, he devotes an unusual amount of this book to the subject of nomenclature and classification of bacteria. In fact, all of chapter six is devoted to that subject. Instead of the usual many pages about methods to identify pathogenic bacteria, there is much on such subjects as water bacteriology, sewage treatment and bacteriology, the bacteriology of milk products, and the use of bacteria in such industrial processes as the making of bread, vinegar, fermented milks and wines. There is a chapter on food preservation, including home canning and the industrial preservation of foods, also a chapter on food poisoning and allergic reactions due to foods. The last three chapters have to do with immune bodies, and the theories and varieties of immunity.

The statement made concerning the glossary in this book in the review of the first edition published in *THE JOURNAL*, May 4, 1929, is still applicable. It was as follows: "A truly remarkable feature of the book is the glossary, which, presumably designed as a help to the student, defines pus as 'the product of suppuration' and suppuration as 'formation of pus'. Fixation is stated to be 'the act of holding fast' and contact the 'mutual touching of two agents'. A sanitarian is defined as 'a public health officer'." Such definitions are especially notable for their extreme simplicity.

Endocrinology Clinical Application and Treatment By August A. Werner M.D. F.A.C.P. Assistant Professor of Internal Medicine St. Louis University School of Medicine Cloth Price \$8 50 Pp 672 with 263 illustrations Philadelphia Lea & Febiger 1937

The appearance of each of the many new textbooks on clinical endocrinology brings with it the pious hope that here at last is a complete, competent and highly critical dissertation. So much nonsense has been written on the subject in journals and books and in the advertising "literature" of the drug houses and so chaotic is the actual therapy of glandular disturbances, real and alleged, that a clear, simple and at the same time iconoclastic discussion of the whole field is urgently necessary.

Dr. Werner's book, while among the best yet written on the subject still falls far short of this goal. This should not be surprising no matter what the merits of the author, endocrinology is now too vast a subject and it is developing at too fast a pace to be adequately covered in its entirety by one man. This is manifested in the present case by markedly uneven treatment accorded the various subjects, the sections on gonadal

disturbances, for instance, are generally excellent, while that on the adrenals is quite inadequate and in many respects erroneous and misleading.

But with all its shortcomings, and there are many, this is nevertheless a useful book and the author is to be commended for its valuable features. The style is lucid, simple and direct. The text is obviously written for the average practitioner and he will find it understandable. The illustrations are excellent and numerous, much attention has been paid to the convenience of the reader in their arrangement throughout the book. Case histories, both from the author's own practice and from the literature, are liberally distributed in the text. Unlike other popular tomes on the subject, the author is commendably cautious about the nature of the commercial glandular products he recommends, though it is unfortunate that of the preparations mentioned most appear to be manufactured by one firm, the author even employs this firm's trade names to represent active principles in several instances. The nomenclature in general could be much improved.

A serious fault is the tendency to philosophize and to theorize about the specific nature of the glandular dysfunctions underlying many of the clinical syndromes described. Much of this hypothetical material has only a nebulous basis and it may lead to specific endocrine therapy where it is not indicated. In endocrinology, and particularly in clinical endocrinology, the words "we do not know" are still adequate to all but a small fraction of the subject, one of the best services any author can perform is to point out clearly the limitations of our knowledge. This Dr. Werner has actually done in numerous instances, unfortunately not in more.

The book is beautifully printed with regard to both text and illustrations, the former is marred by a sprinkling of typographic errors which it is hoped will be corrected in subsequent printings.

Failure of the Heart and Circulation By Terence East M.A. D.M. FRCP Physician Kings College Hospital Cloth Price 2s 6d Pp 130 London John Bale Sons & Curnow Ltd 1937

Dr. East has written an excellent small book on the failure of the heart and circulation in the series of pocket monographs on practical medicine. This little volume is extraordinarily concise and clear. Among the special features to be recommended are chapter II, on the defaulting ventricle, chapter III, on the causes of heart failure, chapter IV, on the pulmonary effects of heart failure and the statement that dyspnea and cyanosis occur in mitral stenosis before congestive failure sets in, chapter VII, on special causes of heart failure, chapter VIII, on heart failure in pregnancy, with the recommendation of paraldehyde as a safe and useful hypnotic when others fail, the emphasis on pulmonary congestion in left ventricular failure, the so called dry failure before peripheral edema appears, the indications for the use of quinidine, the advisability of trying digitalis first in auricular flutter, particular emphasis on suitable diets, the details of massage and exercise in the after-treatment (pp 101 to 103), and the consideration of total thyroidectomy. It is especially to be noted that the author states his belief that digitalis may be helpful in heart failure even when the rhythm is normal, contrary to some of the recent opinions of the English school. An interesting point appearing on page 32 is that dyspnea is apparently not increased as the result of the rise of venous pressure in the head by compressing the veins in the neck by a pneumatic cuff. The author writes of the practical value of the histamine method of determining the circulation rate. He apparently has had a good deal of experience with this method clinically, and it would be of interest to have others confirm his opinion.

There are a few statements which may be open to question. On page 1 peripheral failure is said to be much rarer than central or heart failure, but certainly in slight degree at least peripheral failure is common, as for example in infectious diseases, from blood loss, in accidents, and even in simple syncope. On page 11 atheroma of the coronary arteries is said to be the commonest cause of defects of the myocardium causing failure, the word 'defects' here needs the qualifying definition of 'destructive lesions'. In chapter IV one might add that the reduction of vital capacity in congestion of the lungs is due probably not only to the rigidity of the lungs but also to the

reduction of air space. On page 34 there is an implication that the term "cardiac asthma" is not a suitable one because of the possibility of the confusion with bronchial asthma. It is, however, the experience of most observers of patients with asthmatic breathing in the course of an attack of left ventricular failure that the asthmatic breathing is simply set off reflexly. There may or may not be asthmatic breathing with pulmonary congestion, but cardiac asthma as such must be considered a definite entity. The value of atropine as given with morphine in the treatment of acute pulmonary congestion, with or without cardiac asthma, is doubtful. The definite disadvantage of atropine is its tendency to raise the heart rate. Certainly the morphine is the most important therapeutic measure. More study should be made of the problem of the use of atropine under these circumstances. On page 51 gallop rhythm is discussed and is noted as presystolic. The most serious type of gallop rhythm is protodiastolic or middiastolic in time, and in such cases only with very fast heart rates does the third sound closely approach the first sound. The presystolic gallop rhythm is rightly ascribed to auricular action (with or without prolongation of the PR interval) but it may occur without dilatation and failure of the left ventricle, whereas the protodiastolic gallop rhythm is more serious and almost invariably means great weakness of the left ventricle. On page 53 the systolic murmur of mitral incompetence due to ventricular failure is called "low pitched," but sometimes it may be higher pitched and very loud. On page 57 emphysema and bronchitis are said to be the commonest causes of the few cases of primary right-sided failure, but in parts of the world where rheumatic heart disease is common, mitral stenosis ranks far ahead of emphysema and bronchitis. On page 60 nutritional edema should be mentioned in differential diagnosis. There is too much emphasis on the rare phenomenon of syphilitic obliteration of the pulmonary arterioles, called Ayer's disease. This is too rare for more than the briefest mention in a small book of this sort. On page 83 the emergency use of digitalis is described but the dose given is smaller than sometimes indicated. On the other hand the daily ration for the maintenance of digitalization stated on page 86 as 3 grains of the powdered leaf is rather too high for most patients. On page 88 there is a note as to two uses of epinephrine, but it may be useful in a third way in helping to control asthmatic breathing in cardiac asthma. Mention should be made on page 100 of the occasional and serious complication of infarcts of the lung in the presence of congestive failure. It would be well, too, to amplify the discussion of the treatment of cardiovascular syphilis. The importance of continuing treatment, for example, by alternate carefully regulated courses of bismuth and arsenic compounds over a period of at least two years and then at intervals afterward should be emphasized. Finally, it should be added on page 115 that in skilled hands paravertebral alcohol injection for the relief of angina pectoris has been a useful procedure, well worth further trial.

It is a pleasure to recommend this book for the use not only of internists particularly interested in cardiac disease but also to the general practitioner and medical student.

Appertizing or the Art of Canning Its History and Development. By A. W. Blitting, M.D. Food Technologist Research Laboratory National Canners Association. Cloth. Price \$7. Pp. 552 with illustrations. San Francisco: Food Machinery Corporation (The Trade Pressroom) 1937.

This book is a valuable contribution to the highly developed art of canning. It covers the history and development of commercial canning procedures and discusses the technical aspects of large scale canning of individual products. The name "Appertizing" has been coined by the author in honor of the Frenchman Nicolas Appert, who in 1810 announced the results of his experiments on the preservation of foods and thus laid the foundation of the canning industry of today. There is a brief appraisal of the work of Appert in the introductory portion of the book. A number of important papers are reprinted for their historical significance. They include the report by H. L. Russell on "Gaseous Fermentation in the Canning Industry," first published in 1895, and the report by Samuel C. Prescott and W. L. Underwood on "Micro-organisms and Sterilizing Processes in the Canning Industry" first published in 1896. Following the historical portion the author has presented a detailed description of the technique of canning indi-

vidual products, the subjects being listed alphabetically. A general idea of the type of discussion may be gathered by listing the headings under a product such as grapefruit. There is an introductory paragraph about the history of the cultivation of this fruit, followed by a discussion of the history of canned grapefruit which includes statistics regarding the growth of the industry. The remaining material is presented under such headings as raw material, sizing, peeling, lye peeling, filling, exhausting and cooking, recommended label weights and United States standards for grades of canned grapefruit. The subjects are discussed primarily from the point of view of the commercial canner, and the technologic rather than the nutritional aspects are emphasized. The book is a valuable summary of the art of canning and should be of interest to all commercial and institutional packers.

Osnovy likvorologii. Anatomiya fiziologiya fiziko khimicheskie i biologicheskie svoystva. Metody issledovaniya. Patologiya. [By] A. P. Fridman. [Study of Cerebrospinal Fluid. Anatomy. Physiology. Physicochemical and Biologic Properties. Methods of Study. Pathology.] Cloth. Price 10 rubles. Pp. 472 with 97 illustrations. Leningrad: Gosudarstvennoe izdatel'stvo biologicheskoy i meditsinskoy literatury 1936.

This volume in Russian is the second edition of the *Principles of Liquorology*. It is based on experimental and clinical investigations of the author carried out at the All Russian Institute of Experimental Medicine (V. I. E. M.). The aim of the author is to present in a brief form data collected from the universal literature as well as a brief summation of his own observations and experiments. The attempt is rather to outline the principles of the new discipline which the author calls "liquorology" than to present an exhaustive presentation of the subject. In the discussion of the physiology of the cerebrospinal fluid he attempts to elucidate the questions of production and absorption of the fluid of its statics and its dynamics. He rejects the concept of cerebrospinal fluid as a lymph or a blood filtrate. A special chapter is devoted to the buffer function of the walls of the channels of the cerebrospinal fluid, the study of brain buffer in the normal and pathologic states. Of a particular interest is the author's observation on the intimate relationship between the cerebrospinal fluid and the fluids which bathe such important organs of sensations as the eye, the ear and the nose. This, in his opinion, points to the importance of the role of the liquor in metabolic exchange between the brain and the organism as a whole. Despite the modest claims of the author, the book is a complete textbook on the subject of the cerebrospinal fluid. It contains chapters on the anatomy, physiology, the buffer function of the brain, methods of obtaining the liquor, its investigation, the various biochemical, colloidochemical and biologic reactions, diagnosis and therapy. The last chapter deals with the peculiarities of the liquor in animals. Each topic is adequately treated. The abundant historical references and the extensive bibliography add much to the unity and comprehensiveness of the text.

Spontane und strahleninduzierte Mutabilität. Von H. Stubbe. Probleme der theoretischen und angewandten Genetik und deren Grenzgebiete. Herausgegeben von H. Böhm et al. Redigiert von W. F. Helnig. Boards. Price 6.80 marks. Pp. 190 with 12 illustrations. Leipzig: Georg Thieme 1937.

This book is the first of a series of about fifty volumes which will discuss special questions of genetics for the non-specialist in a monographic form by the most competent authors in their respective fields. The present volume gives a comprehensive and competent review of the present situation with regard to the induction of mutations by irradiation. In a brief introductory chapter on spontaneous mutability, the different types of mutations (gene mutation, chromosomal mutation, genoma mutations and mutations outside the genoma) and the known conditions producing these mutations, other than irradiation, are discussed. After a short historical review of the development of radiation genetics a brief yet comprehensive discussion is given in detail of our present knowledge substantiated by experimental evidence regarding the effect of radiation on the gene material. This is discussed according to the effects on the gene, the chromosome and the genoma. Regarding the effect of radiation on the gene, the most important conclusions are as follows. The quality of the experimentally produced mutation does not differ in any respect from those mutations which occur spontaneously. Irradiation only increases the number of the

mutations There is a linear proportion between the gene mutation rate and the dose of radiation Regarding the effect of different qualities of rays, it can be concluded that this effect depends on the penetrating power of the rays and that every quality is able to produce mutations if only enough radiating energy is delivered to the cells There is no difference in the effect of the mutating power of irradiation between the hardest and the softest parts of the spectrum, provided the dose is the same The many special questions related to mutation by irradiation are discussed in detail, as far as substantiated experimental evidence is available, and the new problems arising are briefly sketched The author never loses himself in speculation Following the discussion of the experimental evidence, the practical consequences drawn from this theoretical field are briefly indicated, such as the application of radiation genetics to animal and plant breeding and the importance of protection from radiation in man It is surprising how this field, which began its development only in 1927 with the classic experiments by H J Muller, has developed in ten years into an important specialty of genetics with the prospect of many theoretical and practical applications in biology and medicine in the future It is certainly valuable to have on hand this convenient, competent and critical guide through the huge amount of literature by an author who has made important contributions to this field himself

Principles and Practice of Public Health Dentistry By J A Salzmann DDS Head of Dental Service of New York City Vocational Schools With a foreword by Alfred Walker DDS FACD Member of New York State Board of Dental Examiners With a special chapter by John Apple McCall AB DDS FACD Director of Murry and Leonie Guggenheim Dental Clinic New York City and by Harry Strusser DDS Chief of Dental Division New York City Department of Health Cloth Price \$4 Pp 584 with illustrations Boston Stratford Company Publishers 1937

Beginning with a discussion of the evolution of preventive dentistry, this work covers the organization of dentistry and public health, the role of official and unofficial public health agencies in dentistry and the dental public health program The great amount of material assembled with accompanying bibliographies, makes it an extremely valuable source book on nearly all phases of dentistry It shares the defects, as well as the advantages, of any book which attempts to cover so wide a field The attitude toward sickness insurance and the field of the state in medicine is indefinite and is weakened by almost exclusive dependence on nonmedical writings, many of which are already outdated and some of which have been largely discredited It is strange that in such a comprehensive discussion there is practically no reference to studies prepared by medical or dental organizations, some of which, at least, are much better sources of information than the works quoted and the use of which would have avoided some of the errors

Os hormônios testiculares Por Raul Franco de Mello Paper Pp 83 with 9 illustrations Sao Paulo Instituto Butantan 1936

This is a contribution to the knowledge of testicular hormones from studies and experiments performed at the Butantan and Oswaldo Cruz institutes The following subjects are covered in the different chapters of the book history of testicular hormones, results of castration and transplantation of a testicle in man and other vertebrates, relations of the hypophysis and the pineal body to gonads and sexual functions, testicular secretion and chemistry of the testicular hormone From the book it is manifest that certain sexual and individual characteristics of mammals, birds, amphibians, fish and some invertebrates originate from and persist in influences of the sex glands which have a morphogenic and conservative influence on the genitals estruation and the psychosexual behavior of man and animals as well as on the evolution of physiologic phenomena and the development of structures unrelated to sexual functions, as that of the body, the hair of certain animals and the feathers of birds Men and animals lose, by castration the sexual differential characteristics of their type and attain a type that is common to the two sexes The later in life castration takes place, the stronger is the persistence of the sexual characteristics after castration It is probable that the somatic cell of mammals and birds is sexually indifferent and differentiates to either sex during embryonic life The testicular hormone is secreted by interstitial cells and controls the development of the most important sexual characteristics There is a reciprocal

functional relation between the hypophysis and the testicle Hormones of the hypophysis stimulate the germinative epithelial cells of the gonads to secrete a hormone that controls secretion of hypophysial hormones Rupture of the equilibrium of the hypophysial testicular relations from destruction of the germinative epithelium results in suppression or diminution of the testicular hormone with consequent hyperfunction of the anterior lobe of the hypophysis In cases of destruction of the germinative epithelium of the testicle, induced by any one of several different means, the hypophysis enters in hyperfunction and shows histologic changes There are, locally, castration cells and basophilia The testicle continues secreting masculine hormone in sufficient quantity to maintain the functions of accessory genitalia The existence of two different testicular hormones seems to be a fact that will be clarified by further chemical studies of the testicular hormone A page of bibliography is at the end of the book

The Practice of Ionization By J Newton Dyson MRCs LRCP With a foreword by Elkin P Cumberbatch MA BM DRME Cloth Price \$1 50 6s Pp 178 with 9 illustrations London Henry Kimpton 1936

Ionization, or iontophoresis, has come to the fore in recent years because of the enthusiasm held for it in certain quarters It is one of the simplest and oldest forms of electrical treatment One of the objects of this book is to indicate the uses of ionization, its various actions and its limitations, and thus aid in avoiding confusion or disappointment The electric current is described in some detail, as is the apparatus and the method of application The clinical discussion deals with arthritis, deafness and tinnitus, fibrositis, the nervous system, and diseases of the skin and special organs Claims made for the beneficial effects of ionization in certain conditions need further substantiation The reviewer has for several years tried ionization in every form for deafness and tinnitus without succeeding in proving that it possesses any merit for these conditions It is questionable whether it 'produces a rapid absorption of the products of acute inflammation' or whether it is possible 'to find a marked relief of pain and swelling, if present, as the result of only one or two applications of this current to an acutely inflamed muscle' The description of technic for treating the nasal sinuses demonstrates a lack of anatomic knowledge It is no simple matter to push a metal rod through the natural ostium of a nasal sinus, as is suggested, nor is the following procedure practical, as recommended by the author 'When the treatment is ended, a strip of gauze soaked in some disinfectant solution is pushed with a probe or fine forceps to the bottom of the sinus' The erroneous statement that Mr Philip Franklyn devised the method of treating hay fever with ionization indicates the author's unfamiliarity with the literature The book is an enthusiastic exposition of a method which possesses merit in a limited number of conditions but certainly not in as wide a range as the author would have one believe The positiveness of statements and claims is not conducive to the best interests of research for ionization or, for that matter, for electrotherapy in general

What Every Athlete Should Know By John Ernest Gignoux BS MD Member of Cornell University Track Team 1895 1896 1897 1898 Fabriloid Price \$1 Pp 82 with 2 illustrations New York Stadium Press 1937

The author, a physician, and formerly a member of several Olympic athletic teams, opens his book with an interesting historical account of the Olympic Games For almost twelve centuries beginning about 776 B C, these games were held in Greece every four years Long after Greece became a part of the Roman Empire, the Roman Emperor Theodosius, having become Christianized, considered the Pagan games harmful and stopped them in the year 394 A D In 1896 the Olympic Games were revived in Athens in a stadium which had been built about 330 B C and had been recently restored It is 26 miles from the plains of Marathon, from where, after the Greek military victory a runner carried the news to Athens and then fell dead from exhaustion The present-day Marathon is a 26 mile race The author follows his entrancing bit of history with a review of the human anatomy that is especially significant in the development of athletes and with some good advice on physical training

Die akute Mittelohrentzündung Eine Darstellung für den Dienst am Kranken. Von Doz. Dr. med. Helmuth Richter, Oberarzt der Universitäts-Klinik für Ohren, Nasen und Kehlkopfkrankheiten, Erlangen. Boards. Price 3.20 marks. Pp. 57 with 18 illustrations. Leipzig: Curt Kabitzsch, 1937.

Richter's conception of otitis media is an elaboration of Politzer's old dictum that all the air spaces in relationship with the middle ear are involved to a greater or lesser degree in an otitis media. He also believes that the latter is only a local manifestation of a constitutional or general infection. This may be specific, such as the exanthema, tuberculosis and syphilis, or nonspecific, such as grip and the common cold. Cases are divided into three groups depending on the general resistance of the patient: the acute catarrhal, occurring in eurasian persons, the necrotic, which is found in the dyscrasic, and the otitis acutissima, in which the overwhelming virulence of the invader finds easy access to extratympanic structures regardless of the state of local or general resistance. The elaboration of these three types forms the subject matter of this monograph which seeks to explain the phenomena on practical clinical grounds. The approach and the treatment of the subject matter are novel and serve to enliven a topic which to most otologists has become rather stale and hackneyed.

Dextrose Therapy in Everyday Practice A Survey of the Literature 1900-1936 on the Experimental and Clinical Studies Applicable to Medicine and Surgery. By E. Martin, Sc.D. With forewords by W. N. Haworth, F.R.S., Director of the Department of Chemistry, University of Birmingham, England, and Bernard Fantus, M.D., Professor of Therapeutics, University of Illinois College of Medicine, Chicago. Cloth. Price \$3. Pp. 451 with 44 illustrations. New York & London: Paul B. Hoeber, Inc., 1937.

This scholarly and elaborate monograph on dextrose medication is a monument to the enormous development that has occurred in the therapeutic use of parenteral dextrose therapy. After a historical introduction the author discusses the surprisingly complex chemistry of dextrose and its equally complex fate in the system. Especially instructive are the dextrose tolerance curves secured under normal as well as abnormal conditions. The bibliography, which reaches the staggering total of more than 2,000 citations, in itself justifies a place for this book in every medical library. It should be emphasized at the same time that the point of view of the book is thoroughly practical, as evidenced by the clinical classification of the therapeutic uses of dextrose, which are discussed in theoretical as well as practical detail.

Chirurgische Indikationen Von Rudolf Nissen, o. Prof. d. Chirurgie, Direktor der I. Chirurgischen Klinik der Universität Istanbul. Paper. Price 3.50 florins. Pp. 177. Leiden: A. W. Sijthoff's Uitgeversmaatschappij N.V., 1937.

This small volume, written in German, treats of indications, contraindications and the choice of operative procedures in almost every field of general surgery. The author kept in view a twofold object, to emphasize the so-called absolute indications for immediate intervention and to elaborate on the question of intervention and the choice of operation in borderline cases. Undoubtedly the author intentionally omits illustrations as well as literary references. When considering a controversial point such, for example, as the question of drainage versus nondrainage after a cholecystectomy or the choice between a palliative and a radical gastric resection for the cure of a deep-seated duodenal ulcer the author states his own preference instead of leading the reader into a maze of contradictory opinions. The result is a compact volume containing a well-balanced, authoritative well-thought-out discussion of the most important problems in the field of surgical indications, contraindications and choice of the proper type of operation.

Poisons, Potions and Profits The Antidote to Radio Advertising. By Peter Morell. Cloth. Price \$2. Pp. 292. New York: Knight Publishers, Inc., 1937.

This is said to have been compiled from material contained in the Consumers Union's files and is intended to serve as a consumers' handbook to cover new material not available when '100,000,000 Guinea Pigs' was published. The volume, with rare courage, takes the radio networks to task for the twaddle and buncombe that is used to boost patent medicine sales under the guise of radio entertainment. There are forceful and entertaining chapters on such subjects as beauty at any price, the slenderizing way to death, the yeast hoax, dental nostrums and peddling human misery for profit. There are

also some interesting individual tables on advertising expenditures. For those interested in the methods and wiles of "patent medicine" merchandising, the work adds considerably to the ever-increasing expose.

Urovskaya bolezn v Zabaykale Vypusk vtoroy. Pod redaktsiei S. V. Dyachenko et al. Vostochnosibirskiy kraevoy otdel zdoroookhraneniya i vostochnosibirskiy meditsinskii institut [Urovsk Disease (Osteoarthritis deformans) in Transbaikalia. Second edition.] Paper. Price 4 rubles 50 kopeks. Pp. 208 with 32 illustrations. Irkutsk: Vostochnosibirskoe kraevoe izdatel'stvo, 1937.

The present is the second volume of collected papers published by the Urovsk Scientific Institute. A large number of the population of this Far Eastern territory had been known for the past century to exhibit signs of a peculiar disorder of the joints to which the original investigators, Kashin and Bek, gave the name of endemic deforming osteoarthritis. The incidence of endemic goiter is particularly high and the two conditions are frequently associated. Kashin-Bek or Urovsk disease is characterized by a chronic progressive course with symmetrical involvement and deformation of joints and epiphyyses of the long bones, particularly the extremities. The disease is associated with a peculiar form of a genuine congenital rickets and with pathologic alterations in the lymph nodes, the thyroid thymus, spleen and the vascular system. The tendency of the disease is to progression and deformation of the osseous and muscular systems. A relative avitaminosis, lack of vegetables in the diet, insanitary conditions and the peculiarities of drinking water contribute, in the opinion of the investigators, to the etiology of both the continued rachitic state and the goiter.

Health and a Day Addresses. By Lord Horder. Cloth. Price 7s. 6d. Pp. 213. London: J. M. Dent & Sons Ltd., 1937.

The title of this book derives from the lecture by Emerson, who wrote "Give me Health and a Day and I will make the pomp of emperors ridiculous." Two essays are included dealing with such subjects as the strain of modern civilization, the relationship of the physician to many aspects of modern society, the advancement of medical science, and euthanasia. Dr. Horder is known for his interests in many social medical fields. He is a proponent of tranquility, of quiet and of relaxation. He believes implicitly in the personal relationship of doctor and patient and in the necessity for considering the individual human being as an individual if he is to survive. He deprecates the too great invasion by the machine and asserts that where the machine is greater than the man the patient perishes. These are good medical essays, printed in large type on good paper, and should furnish welcome relaxation and at the same time stimulation to every medical reader.

Elements of Orthopaedic Surgery By N. Ross Smith, M.B., Ch.B., F.R.C.S., Orthopaedic Surgeon, Cornell Hospital, Poole, England. Foreword by R. C. Elmisle, O.B.E., M.S., F.R.C.S., Orthopaedic Surgeon, St. Bartholomew's Hospital, London. Cloth. Price \$4. Pp. 216 with 99 illustrations. Baltimore: William Wood & Company, 1937.

This pocket size book was written by two able and well-known British orthopaedic surgeons. It is not a compendium; it is a miniature of larger textbooks and covers the essentials of the specialty. There are eleven chapters and three appendices on physical therapy, splints and appliances and plaster of Paris technique. It is an ideal book for nurses, physical therapists, social and welfare workers, interns and practitioners who have need of a conversing knowledge of orthopaedic surgery.

The Seamen's Handbook for Shore Leave By Mrs. Henry Howard. Sixth edition. Fabrikoid. Price 50 cents. Pp. 435. New York: American Merchant Marine Library Association, 1937.

As an aid to American sailors the American Merchant Marine Library Association has published this excellent, pocket size flexible covered guide. The volume contains an alphabetical list of 440 world ports, with the names of inexpensive hotels, hotel rates, information on legal aid hospitals, venereal disease clinics, doctors, dentists, laundries and amusements. It also gives specific warnings about conditions in various ports, information concerning money, radio call signals for emergency sickness and a vast amount of additional data. Many public service organizations cooperated in the development of this most useful little book. It is among the most practical items of its kind and will be found exceedingly useful not only by sailors but by anybody else traveling round the world.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts Jurisdiction of Federal Court to Enjoin Enforcement—Arthur O Borland and the other complainants in this case were graduated by the California University of Liberal Physicians, an institution incorporated under the laws of California. Without obtaining a license under the medical practice act, they proceeded to engage in the practice of naturopathy in Hawthorne, Calif., after paying a license fee to the city. Proceedings were instituted against them under the medical practice act and each complainant was found guilty and fined \$100. Thereafter they appealed to the superior court of California for Los Angeles County but that court refused to entertain jurisdiction of the appeal because it had not been effected within the period specified by law. The next move of the complainants was to file a complaint in the United States district court for the southern district of California, central division, asking the federal court to enter a decree declaring the medical practice act unconstitutional, the judgment of the state court nugatory and void, and to issue an order restraining the defendants from further annoying and harassing the complainants. The district court dismissed the bill of complaint, and the complainants appealed to the United States circuit court of appeals, ninth district.

The practice of naturopathy, the court said, is defined in Webster's Dictionary as "a system of physical culture and drugless treatment of disease by methods supposed to stimulate or assist nature." It was apparent to the court that the complainants asked relief against the judgment rendered by a state court on the ground that the act on which the action was predicated was unconstitutional and void, but that defense could have been presented in the state action. The bill of complaint showed affirmatively that the state court had jurisdiction of the parties in the action before it and that the violation charged was a misdemeanor over which the justice court had jurisdiction. Under these circumstances, the federal district court did not have jurisdiction of the suit and properly dismissed the bill. In a specially concurring opinion, one justice pointed out that under the federal judicial code a writ of injunction may not be granted by any court of the United States to stay proceedings in any state court except in cases in which such injunction may be authorized by any law relating to proceedings in bankruptcy. 28 U S C A Sec 379. The judgment of the district court dismissing the complaint was therefore affirmed.—*Borland et al v Johnson*, 88 F (2d) 376.

Charitable Hospitals Exemption from Taxation—An Iowa statute provides that "all grounds and buildings used by charitable, benevolent institutions and societies solely for their appropriate objects, not exceeding 320 acres in extent and not leased or otherwise used with a view to pecuniary profit," shall be exempt from taxation. For about fifteen years prior to March 11, 1933, a physician owned two houses in Readlyn, Iowa. He lived in one of the houses and used the other as a private hospital. On the date named, the physician, his wife and a nurse in the hospital formed a corporation known as the Readlyn Hospital for benevolent, charitable and scientific purposes, and not for pecuniary profit. The two houses were conveyed to the corporation and thereafter it was claimed that the property owned by the corporation was tax exempt under the provisions of the Iowa statute quoted. The county officials advertised the property for sale for the nonpayment of taxes and the corporation sought to restrain the collection of the taxes. The trial court decided against the corporation, which then appealed to the Supreme Court of Iowa.

After the conveyance of the property to the corporation the physician continued to use one house as his residence and two rooms in the hospital building for his offices. The corporation contended that the recital in articles of incorporation that the Readlyn Hospital was organized for charitable and benevolent purposes should be controlling in determining its objects and

purposes. But, said the court, while the objects and purposes of a corporation as expressed in its articles of incorporation may be considered, the recital is not controlling in determining the question of exemption from taxation. This question must be determined from the use made of the property rather than the declaration made in the articles of incorporation. Statutes exempting property from taxation must be strictly construed, and, if there is any doubt about the question, it must be resolved against the exemption and in favor of taxation. A person claiming exemption from taxation must show clearly that the property is exempt within the terms of the statute. The court felt constrained to hold that much of the property involved in this case was used by the physician in his private practice and for his personal gain and, since the property so used formed a part of the property claimed to be exempt from taxation under the statute, the corporation was not entitled to the restraining order. The decree of the trial court against the corporation was therefore affirmed.—*Readlyn Hospital v Hoth, County Treasurer (Iowa)* 272 N W 90.

Evidence Admissibility of Statements of Patient to Physician—Statements by an injured person as to his condition and symptoms at the time of his examination by a physician, called for the purpose of treatment, are admissible as circumstantial evidence of the existence of the physical condition of the patient. A narrative statement, however, with respect to the cause of the injury and the circumstances attending the accident made to such a physician so long after the accident as not to be part of the res gestae are inadmissible, since they are a narrative of past events in the nature of self-serving declarations and hearsay. If this were not the rule, said the U S circuit court of appeals, eighth circuit, an injured person might have himself examined by a physician called for treatment, relate to the physician the alleged facts with reference to the circumstances under which he received his injuries, and place this physician on the witness stand to narrate those alleged facts without himself having to take the witness stand at all. By so doing he could deprive the defendant of the right of cross-examination. Applying the rule thus stated, the court held in this case that the trial court erred in receiving the testimony of physicians which purported to give the insured's version as to the circumstances under which he received his injuries. The judgment for the insured was consequently reversed.—*Aetna Life Ins Co v Quinley*, 87 F (2d) 732.

Malpractice Liability of Physician for Unauthorized Act of Hospital Nurse—The plaintiff was born in the Evangelical Deaconess Hospital, a cesarean operation being performed by the defendant. The baby was taken from the operation room to the nursery by the obstetric supervisor of the hospital, who, about an hour later, without the direction or knowledge of the physician, instilled a solution in the baby's eyes from a bottle indicating that it contained a 2 per cent solution of silver nitrate. Severe injury to the eyes resulted, eventuating in blindness. Substantial vision, however, was later regained. Subsequently the baby sued the physician in the U S district court for the northern district of Illinois, western division, and obtained a judgment for \$7,750.50. The physician then appealed to the U S circuit court of appeals, seventh circuit.

The principal question before the court on appeal was the liability of the physician for the unauthorized act of the hospital nurse. At the time the plaintiff was born, there was no law in Illinois requiring the instillation of a solution of silver nitrate or any other solution in the eyes of the new born. No duty, therefore devolved on the defendant to cause any such solution to be instilled. Apparently in this particular hospital a 2 per cent solution of silver nitrate was instilled by nurses as a matter of routine in all normal childbirth cases. Although the plaintiff's birth was not a normal case, the nurse presumably considered it her duty as an employee of the hospital to instill the solution. It was contended that if the physician deemed the instillation unnecessary he should have instructed the nurses that it be omitted. With this contention the circuit court of appeals disagreed. While the physician gave no such instructions neither did he caution the nurse not to fall down and drop the baby nor give orders that on reaching the nursery they

should not give the baby a cold shower. No inferences are to be had against the physician under the circumstances here present, said the court, for his failure to give any negative orders.

The nurses assisting in the operating room at the time of the delivery were the agents and servants of the physician, for they were under his direct control and supervision and subject to his orders. To say, however, that such relation continued in all postnatal treatment administered by the nurses or by the hospital would cast too great a burden on the physician. Even though there may be basis for the contention that the relation of master and servant continued to the extent that the nurses carried out orders and directions of the physician, yet the undertaking of a treatment neither expressly nor impliedly authorized was beyond the scope of their authority as his agents. The physician may not be held liable for the negligence of another assuming to act, not under his directions, but in pursuance of an independent judgment, in the absence of any duty imposed on the physician to perform the act.

In assuming the care of the mother and child, the physician impliedly contracted that he possessed and would use in the treatment of his patients a reasonable degree of skill and learning. He owed a duty toward each to exercise such reasonable care and skill as a reasonably prudent and careful physician and surgeon would use under like circumstances. So far as the record discloses, the physician fully and skilfully performed this duty. He was likewise responsible for the negligent acts of others who were his agents or employees and who were acting within the scope of their employment or agency. But under the circumstances here present it cannot be said that those responsible for the most unfortunate condition of the baby's eyes were in any sense acting for or on behalf of the physician. The trial court should have instructed the jury to find for the physician. The judgment against the physician was therefore reversed and the cause remanded.—*Harlan v Bryant* 87 F (2d) 170

Sarcoma of Hip in Relation to Trauma—Sellon a member of the crew of the steamer *H A Scandrett*, fell when a knob of one of the steamer's doors pulled off as he was attempting to open the door and his right hip struck a hatch clamp causing the hip to become black and blue, and painful. Shortly thereafter a lump appeared at the site of the injury, which later proved to be a malignant sarcoma. Sellon sued the owner of the vessel to recover damages for the injuries he had sustained. He obtained a judgment in the trial court but died shortly thereafter as a result of the sarcoma. The owner of the vessel appealed to the United States circuit court of appeals second circuit, and the administratrix of Sellon's estate was substituted as appellee.

In the trial court, medical expert witnesses testified that the sarcoma resulted from the injury to the hip. On appeal, the causal relation between the trauma and the sarcoma was not questioned, other issues having formed the basis of the appeal. The circuit court of appeals however in affirming the judgment of the trial court awarding damages for the injuries sustained, left undisturbed the finding of the lower court with respect to the origin of the sarcoma.—*Sellon v Great Lakes Transit Corporation*, 87 F (2d) 708

Malpractice Compensation Award as Bar to Malpractice Action—A workman injured his right arm, shoulder and wrist in the course of his employment and was treated by a physician selected by the employer. Subsequent to the termination of the physician's attendance, the workman was awarded compensation by the Missouri compensation commission. Thereafter he sued the physician for malpractice contending that by reason of the physician's negligent treatment he was injured. He admitted that by the workmen's compensation award he had been fully compensated for the disability occurring as a result of his industrial injury and its consequent aggravation by the alleged negligence of the physician but contended since the compensation award did not include them, he was entitled to recover damages from the physician for the pain and suffering, and anguish of mind and nervous shock directly and proximately caused by the defendant's negligent treatment and "for any permanent injury or deformity, mortification, disfigurement or future power to earn wages." The trial court sustained a motion to enter judgment on the plead-

ings for the physician, and the workman appealed to the Supreme Court of Missouri, division 1.

The Supreme Court rejected the workman's contention. It could find nothing in the wording of the Missouri workmen's compensation act to justify a departure from the general rule that a workman who has received compensation under a workmen's compensation act cannot recover damages from a physician for an alleged aggravation of his industrial injury due to the negligent treatment of the physician. The Missouri workmen's compensation act by its very terms, said the Supreme Court, provides that "the rights and remedies herein granted to an employee, shall exclude all other rights and remedies of such employee on account of such accidental injury." Even though the section referred to proceeds thereafter in the very same sentence to provide "except such rights and remedies as are not provided for by this chapter," the court held that the workman had been fully compensated by the award. The judgment of the trial court in favor of the physician was accordingly affirmed.—*Hanson v Norton (Mo)* 103 S W (2d) 1

Accident Insurance Death from Ether as Constituting Death by Accidental Means—The Metropolitan Life Insurance Company, under two insurance policies issued to the insured, promised to pay double benefits if the insured's death was the result "directly and independently of all other causes, of bodily injuries sustained through external, violent and accidental means," but excluded death caused directly or indirectly or wholly or partially by disease or bodily or mental infirmity. The insured died while undergoing an operation for the removal of his tonsils. The insurance company refused to pay the double benefits, the beneficiary obtained a judgment in the superior court of Cook County, and the company appealed to the appellate court of Illinois, third division, first district.

The physician who performed the tonsillectomy testified that the insured's death was due to an idiosyncrasy to ether that caused respiratory paralysis. The coroner's physician of Cook County testified that he performed an autopsy on the body and found marked fatty changes in the liver, a moderate hypertrophy of the heart muscle and a passive congestion of the spleen and kidneys. In the opinion of this witness, the insured's death was due to degenerative changes of the heart muscle plus "surgical shock and anesthesia." Other physicians testified that the insured came to his death as a result of the combined effects of preexisting pathologic conditions and the administration of ether. In the opinion of the appellate court, the evidence was clear that the "means" through which the insured lost his life was not accidental. The insured voluntarily submitted to the administration of the anesthetic. There was no claim that the operation was unskilfully performed, nor was there any evidence that the anesthetic was not properly and skilfully administered. The preponderating weight of evidence indicated to the court that the insured was suffering from disease which directly contributed to his death. The evidence showed, therefore that the death was not the result "directly and independently of all other causes of bodily injuries sustained through external, violent and accidental means." The judgment of the superior court was reversed and judgment entered against the plaintiff.—*Libbert v Metropolitan Life Ins Co (Ill)* 7 N E (2d) 336

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1927 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Study of Fatal Cases of Cancer of Scrotum—Henry studied the relation of cancer of the scrotum to occupation of the 1,487 men who had been certified medically as having died of the disease between 1911 and 1935. Of the 1,487 fatal cases coded as cancer of the scrotum by the Registrar General for England and Wales the disease was defined as epithelioma in 903, carcinoma in 362, cancer in 206, rodent ulcer in three, sarcoma in twelve and teratoma in one. The two occupations dealt with in the study are those of chimney sweeps and cotton mule spinners. There were 147 fatal cases of cutaneous cancer in chimney sweeps from 1911 to 1935, of which forty-four were on cutaneous sites other than the scrotum. A comparison of the deaths from cutaneous cancer in sweeps in each decennial age group from 25 shows that prior to 45 years of age the only deaths from cutaneous cancer are those from cancer of the scrotum. The age of the 103 chimney sweeps who died of cancer of the scrotum between 1911 and 1935 varied from 34 to 84 years. The excessive occurrence of cancer of the scrotum in cotton mule spinners was first brought into prominence in 1922 by the publication of Southam and Wilson, which dealt with 141 cases of cancer of the scrotum. In the present series there were 345 deaths from cancer in cotton mule spinners. In fourteen cases additional sites were stated on the death certificate apart from secondary involvement of the inguinal or pelvic glands, liver or peritoneum. A comparison of the deaths from cutaneous cancer in cotton mule spinners in each decennial age group from 25 years shows that each group from 25 to 75 contributes deaths from cancer on cutaneous sites both scrotal and nonscrotal. The percentage of deaths from cancer of the scrotum to the total for cutaneous cancer is at its minimum of 25 at the age of 25 to 34, rises to 87 at the age of 45 to 54, and falls to 647 at the age of 75 to 84. From the age of 85 one death from scrotal cancer has occurred but, contrary to the case of chimney sweeps, no death from cutaneous cancer other than on the scrotum has as yet arisen. There were 136 cases of cancer of the scrotum and thirty-six cases of cancer at another cutaneous site in cotton mule spinners from 1921 to 1925 inclusive, 281 and 145 respectively from 1926 to 1930, and 172 and 107 from 1931 to 1935.

Observations on Macronucleolus of Cancer Cells—McCarty summarizes the results of sixteen observers working independently which abundantly substantiate the fact that

malignant cells possess larger nucleoli than all other cells of any particular organ. Two other observations worthy of mention are that there are intranucleolar bodies evident within the large nucleoli that should not be dismissed too readily as vacuoles or harmless accidental lipid bodies, and George A Wyeth, working with darkfield illumination and incident light, found a minute active, motile body in perfectly fresh, unfixed cancers of the breast. The question arising is whether there is any relation between the enlarged nucleolus, the intranucleolar bodies and the fairly constant active motile body.

Esophageal Varices—Oppenheimer bases his remarks on the observations made on healthy students and on about 100 patients with esophageal varices, all of whom were thoroughly examined clinically and roentgenologically. Anatomically, the x-ray observations vary greatly with the stage of the disease. Three groups stand out: (1) the early stage, marked by a slight and diffuse venous congestion resulting in moderate broadening of the rugae of the lower part of the esophagus, (2) the beginning of the dilatation of larger individual veins which emerge from the submucosa into the mucosal relief marked by small rounded defects seen in the relief of the lower fifth of the tube and (3) generalized enlargement of numerous veins which encroach on the mucosa. In this period the typical vermiform negative shadows predominate. Varices, not being solid anatomic formations, vary in caliber according to influences acting on their filling. Definite variations in size and extent are produced by peristalsis, especially stripping, and by mechanical pressure—that, for example, of a large bolus. In

either case, blood is moved into the lower vessels. In early portal congestion, the blood can still pass into the abdominal veins. Later it is squeezed from the upper varices into lower ones, overfilling the latter. This mechanism, in early stages, makes esophageal varices invisible and, in advanced stages, only a part of the whole extent is visualized. X-ray examination generally does no more than confirm the clinical diagnosis in advanced stages, while in early congestion the clinical recognition often depends on positive X-ray signs. It is necessary, therefore, to demonstrate the mucosal relief of the esophagus when unaltered by peristalsis or mechanical compression. Optimal visualization is present during the short interval between swallowing and stripping. Esophageal varices fill on inspiration. Hence the film should be exposed during forced inspiration. The retardation of the passage through the esophagus varies between a few seconds, in early congestion, and several hours, in terminal stages. It is often due only to mechanical obstruction by the varicose mass. But, in early and in terminal stages, various functional disturbances affecting the cardia also cause esophageal stasis.

Nutritional Factors in Exophthalmic Goiter—A few years ago Hertz was impressed with the number of patients with toxic goiter who gave histories of having started their thyrotoxic symptoms at the conclusion of a reducing program for obesity. After the desired amount of weight had been lost the diet was increased, but the patient found that loss of weight continued, perhaps at an accelerated rate. Along with this, nervousness, tremor and other symptoms of thyrotoxicosis would make their appearance. Means and his associates have encountered thirty-five such cases. In fourteen of these the prethyrotoxic loss of weight was occasioned by reducing cures and in the remainder it was due to a variety of conditions, such as restriction of diet in the treatment of ulcer, ulcerative colitis, diabetes and other diseases leading to malnutrition. The authors warn physicians and patients against too vigorous reducing cures for obesity, and in the preparation of the thyrotoxic patient for surgical intervention urge that the possibility of nutritional disturbances be considered and, if found, that an attempt be made to correct them. The manifestations of nutritional disturbance, which may be found in thyrotoxic patients, include general nutrition changes in musculature, skeleton, hematopoietic system and very likely in the heart and psyche. While these changes may be incidental, they are of sufficient frequency to warrant consideration in the complete management of exophthalmic goiter. The methods of correcting these defects include not only a high caloric diet for relieving general malnutrition but one high in vitamins and minerals as well. For the high caloric intake the chief dependence should be placed on carbohydrate. Excessive protein is undesirable because through its specific dynamic action protein raises metabolism. Fat may be given to whatever extent the patient's appetite demands it. The malnourished thyrotoxic and the psychotic patients as well as those with cardiac insufficiency are considered poor operative risks.

Mechanism of Emotion—Papez attempts to point out various anatomic structures and correlated physiologic symptoms which, taken as a whole, deal with the various phases of emotional dynamics, consciousness and related functions. It is proposed that the hypothalamus, the anterior thalamic nuclei, the gyrus cinguli, the hippocampus and their interconnections constitute a harmonious mechanism which may elaborate the functions of central emotion as well as participate in emotional expression. It is an attempt to allocate specific organic units to a larger organization dealing with a complex regulatory process. The evidence presented is mostly concordant and suggestive of such a mechanism as a unit within the larger architectonic mosaic of the brain. The structures described here are usually represented as dealing with some phase of the olfactory function. There is no clinical or other evidence to support this view. Emotion is such an important function that its mechanism, whatever it is, should be placed on a structural basis. The organization presented here meets adequately the physiologic requirements proposed by Cannon and Bard with respect to the theory of emotion based on diencephalic cortical processes. It is also in agreement with the observations of Dunly that the seat of consciousness is located somewhere near the midline, between the limits set by the corpus callosum and the basal structures of the brain.

Mode of Onset of Epilepsy—Fetterman and Hall observed 160 patients who had had convulsive seizures. In practically every instance an extensive history had been obtained and neurologic, X-ray and laboratory studies were made. Of the patients 102 were considered as belonging to the group with so called idiopathic, or cryptogenic, epilepsy, fifty one to the group with the organic type and seven to the group with the psychogenic type. The mode of onset was correlated with the various features, such as etiology, age at onset, intelligence quotient, family history, eventual severity and response to therapy. The onset occurred abruptly in from 75 to 80 per cent of the cases and mildly in the remainder. Except for the alcoholic group there was remarkable uniformity in this ratio for all etiologic types, the organic and the idiopathic group showing apparently the same percentages of violent and of mild onsets. There was a slight tendency for the lighter modes to occur in young persons. Thus, in 48 per cent of the cases in which the onset was insidious the disease began in the first decade of life, as compared with only 26 per cent in which there was abrupt, violent onset. The investigation shows the significance of early attacks, either abrupt or mild for the development of later chronic epilepsy. There was no important correlation between the mode of onset and the intelligence quotient of the patient. There was only the slightest tendency for milder forms of onset to occur in persons with higher intelligence. This variation may well be erroneous. The mildness of the onset is not a measure of the eventual severity of the epilepsy. Regularly, persons who began with momentary starts or transient visceral sensations later experienced diminution in consciousness and finally, complete loss of consciousness with all the convulsive features of epilepsy. In some instances there was a tendency for epilepsy with a mild

onset to remain mild throughout the course of the disease. There was no important correlation between the severity of onset and the family history.

PseudoCryptorchidism and True Cryptorchidism—Hamilton and Hubert devised a method for the differentiation of true from false cryptorchidism. The rationale is that of obtaining relaxation of those muscles the contraction of which has caused retraction of the testis, if this does not in itself result in the return of the testis to the scrotum, manual palpation is employed. Such relaxation of cremasteric and other muscles is obtained by a general method of approach and by direct application of heat (hot water bag) to the groin scrotum and perineum, the patient lying with the legs apart. The temperature of the water in the bag is maintained at about 115 F. The specific procedure of thermal applications warms the muscles whose contraction causes retraction of the testis and interferes with the return of the testis normally or even when aided by manual pressure. Heating results in relaxation of these muscles, hence the testis may reenter the scrotum, either spontaneously or following increase in the abdominal pressure. When spontaneous descent does not occur, palpation is employed. If the testis cannot be passed into the scrotum by gentle manipulation when the muscles are relaxed, the testis is considered to all intents and purposes to be truly cryptorchid. Precautions should be observed to avoid exciting the patient or inciting the active cremasteric reflexes. This technique reveals the large percentage of pseudoCryptorchid testes that are considered true cryptorchidism by usual tests, even by physicians experienced in the handling of children. Of the sixteen cases referred to the authors by pediatricians, all but six presented a condition of spastic retraction.

Ketosis Developed During Fasting—New experiments along with data from the literature were used by MacKay and Sherrill for a comparison of the extent of fasting ketosis in obese and nonobese subjects. They conclude from the data that unless an obese subject has a fasting ketosis a great deal lower than the average normal person he will probably develop a higher degree of ketosis than the nonobese individual. Obese patients who have less of a fasting ketosis than normal subjects are probably suffering from a different type of obesity, possibly related to disturbances in the endocrine system. This failure to develop a ketosis brings up the question of locked fat in connection with the fat deposits in certain cases of obesity. Because of the ketogenic activity of certain anterior pituitary extracts and their ability to move fat from the stores of the body to the liver, the functional state of this gland in obesity must be considered. A short fast is a useful therapeutic agent for many obese patients and under the proper conditions is not difficult to carry out. The subjects from whom the data were obtained did not have their diet carefully controlled previous to fasting. There is considerable evidence that in further work of this kind rigid control of the preceding diet would be desirable.

Hypervitaminosis D—Hubbard reviews the literature pertaining to the possible effects of toxic dosage, vitamin D poisoning and hypervitaminosis D that may be brought about by massive doses of vitamin D in the treatment of allergic and arthritic conditions. He pleads that a measure of caution be exerted by those physicians who do not have adequate facilities for the observation and control of patients suffering from these conditions and in whom a trial of this therapy might be considered. The advocates for any particular type of therapy extol its virtues but have a tendency toward minimizing any deleterious effects. Hypervitaminosis D may cause cell destruction and calcification which may become involved beyond repair, leading to death. The factors influencing the severity of hypervitaminosis D are the state of the renal pathologic condition previous to massive vitamin D administration, the presence of a sensitive colon or intolerance to any dosage, the proportionate available supplies of calcium and phosphorus and the proportionate available supply of the vitamins having a cooperative or synergistic action vitamins A, B complex, C and F. In the absence of better diagnostic aids for the determinations of hypervitaminosis D than an inexperienced patient's self observation of distress, it behooves physicians to use extreme caution in making use of this therapy. It is also possible that harm may result from indiscriminate vitamin self medication on the part of the public. Vitamin D preparations of all potencies have been greatly overemphasized and oversold to the public. The overcommercialization of these products, the undesirable qualities, which are now being recognized along with their beneficent properties, may have most unfortunate repercussions as time goes by.

Daily Excretion of Estrogenic and Androgenic Substances—Gallagher and his associates outline a quantitative method for the extraction of androgenic and estrogenic materials from the urine. They applied the method on the urines of four normal men and four normal women over a continuous period of from thirty-nine to forty-five days for the men and over a complete menstrual cycle for the women. There were marked fluctuations in the daily urinary excretion of androgens and estrogens in the normal men and women. There was no definite evidence of a monthly cycle in the excretion of either androgens or estrogens in the normal men. In the women the excretion of estrogens was characteristically low during the menstrual flow and rose during the intermenstruum with a double peak in certain instances. The average daily excretions of androgens were from 63 to 68 units for the men and from 42 to 56 units for the women, calculated as international androgen units. The average daily excretions of estrogens, calculated as micrograms of theelin, were from 9 to 12 micrograms for the men and from 18 to 36 for the women. The rates of excretion of androgenic and estrogenic substances do not seem to bear any relation to each other in either sex.

Excretion of Androgenic and Estrogenic Substances—Kenyon and his colleagues observed that two castrated men excreted only traces of androgenic (comb-growth promoting) and estrogenic substances. Seven emuroids excreted on the average a third of the normal amount of androgens, overlapping the normal range on occasion. The output of estrogens was also low. One patient with hypopituitarism excreted only small amounts of both substances. Of four patients with gynecomastia none excreted an excess of estrogenic material. The androgens varied from none at all to a normal amount. Sixteen patients with virilism excreted as a rule normal amounts of androgenic material. The great excess of 480 international units per day was found in one case of carcinoma of the adrenal cortex. The urine of this patient possessed the spectrographic

properties of testosterone, androstenedione or cholestenone rather than of androsterone. It was similar in this respect to certain compounds derived from the adrenal cortex.

Loss of Minerals Through Skin When Sweating Is Avoided—With the exception of the work of McCance in none of the literature did Freyberg and Grant find any information regarding the cutaneous loss of minerals from the healthy adult man who is not sweating. They therefore experimented on two healthy adult men who went about their usual laboratory duties with special precautions only to keep themselves cool enough to prevent sweating. Subject B over a period of seventy-seven days excreted an average of 37 mg of sodium daily. The same subject lost 71 and 131 mg of sodium daily through the skin during two separate experiments. These values illustrate the relative importance of measuring the sodium lost by the two paths of excretion. During the low intake of sodium chloride, particularly, cutaneous excretion cannot be disregarded, for in this experiment more than 14 per cent of the total urinary and cutaneous sodium is lost through the skin. This experiment also shows that the loss of sodium, chloride and other minerals through the skin does not vary with the intake of sodium chloride or with the amount in the urine. Accordingly a twelve hour experiment was carried out while subject B lay nude on a rubber sheet in a room in which the temperature was maintained between 77 and 82.4 F. During this period there was no detectable moisture on the skin. The insensible loss of weight for this period was 397 Gm, 60 Gm was lost as the result of the difference in weight between outgoing carbon dioxide and incoming oxygen, and the remaining 335 Gm was water vaporized from the lungs and skin. About two thirds of the water vapor comes from the skin, thus about 225 Gm of water was vaporized from the skin. It carried with it 32 mg of sodium, 47 mg of potassium, 53 mg of chloride and 34 mg of sulfate sulfur. The insensible loss of water being considerably greater when the subject is up and about, it is obvious that little if any of the twenty-four hourly values of the substances studied could have come from sweat or sources other than the skin.

Does Digitalis Protect Against Diphtheria Toxin?—In view of the importance of the correct treatment of the circulatory collapse which occurs in diphtheria and the results obtained by Myers in his use of digitalis Edmunds and Smith further examined the subject since digitalis has been shown

by many workers to produce cardiac changes that would seem to be detrimental in diphtheria rather than beneficial. The present study was undertaken to determine the degree of protective action, if any, of digitalis, ouabain and strophanthin against diphtheria toxin. About 450 guinea-pigs were used. Daily administration of digitalis or the glucosides was begun, in some experiments, at the time of the toxin injection and continued for six injections, provided death did not ensue within that period. In other experiments the daily administration of digitalis or the glucosides preceded the injection of toxin by from five to thirteen days in order to detect a possible prophylactic action. In still other experiments previous treatment was discontinued at the time of the injection of toxin. The subcutaneous lethal doses of ouabain, strophanthin and tincture of digitalis were first determined in order that certain fractions of these doses might be used for purposes of prophylaxis or treatment. A preliminary series of experiments was carried out in which the protective action of ouabain and strophanthin was determined against varying doses of diphtheria toxin. The results indicate clearly, in contrast to the positive results of Myers with strophanthin, a complete absence of any protective effect from the use of this glucoside. The results with ouabain are also unfavorable to any view that the use of this glucoside is beneficial. In fact the percentage of recoveries is slightly higher with toxin alone than with toxin and ouabain. Myers' results with ouabain agree in general with these. In addition to the pharmacologic evidence, a pathologic study of the affected hearts failed to support the theory that protection was afforded

Orbital Infections Due to Nasal Sinusitis—Hubert points out that orbital infections due to nasal sinusitis may extend into the orbits by direct extension from the diseased bony walls, which separate these sinuses from the orbital cavities, and by the venous blood stream, i. e., by a phlebitis of the veins of the various sinuses, which anastomose with the superior and inferior ophthalmic veins that supply the fatty cellular tissue of the orbits. All orbital infections can be classified in the following groups: (1) inflammatory edema of the eyelids with or without edema of the orbit, (2) subperiosteal abscess with (a) edema of the lids and orbit, (b) spread-

ing of the pus to the lids (erroneously called orbital abscesses), (3) orbital abscess, (4) severe and mild orbital cellulitis and (5) septic and aseptic(?) cavernous sinus thrombosis. In the first group the infection is confined to the nasal sinuses and there is only an inflammatory edema of the lids, which may become markedly swollen. Thirty-one patients belonging to the first group were admitted to the hospital as bed patients. Of these, twenty were successfully treated symptomatically, one had a lid incised, one had the middle turbinate removed and nine had external radical operations. There were five deaths in this group. In the second group the infection involves the bony wall and the periosteum and a collection of pus forms between them. There were forty-six such cases, in nine of which the pus was confined between the bone and the periosteum and in thirty-seven the pus involved the lids. All recovered after surgical treatment. The infection in the third group spreads into the orbital tissue proper either through the orbital wall and fascia or through the venous circulation. Of twenty-two patients, two died of meningitis and one of a brain abscess. In the fourth group the infection extends into the orbital tissues through the venous circulation, causing a phlebitis of the ophthalmic veins. Nine patients had severe orbital cellulitis, six of whom died of meningitis. There were two patients with a mild orbital cellulitis following a nasal infection. They were discharged cured after a few days of local treatment. In the fifth group the infection has extended from the ophthalmic veins or directly from the sphenoid sinus into the cavernous sinus. It is almost impossible to distinguish clinically such an orbital cellulitis from a cavernous sinus thrombosis, unless it is accompanied by an edema over the mastoid emissary. The difficulty in the clinical diagnosis is due to the fact that the signs which are supposed to be characteristic of it are not due to a thrombosis of the cavernous sinus alone but to a phlebitis of the ophthalmic veins. Both of the two cases of septic cavernous sinus thrombosis were fatal. The two patients who recovered were diagnosed as having aseptic cavernous sinus thrombosis. This diagnosis is of course doubtful.

*Renal Hyperparathyroidism Associated with Cushing's Syndrome. J. A. Pons. San Juan and A. M. Pappenheimer. New York—p. 115

Renal Hyperparathyroidism—Pons and Pappenheimer report a case in which the classic features of the Cushing syndrome were combined with those of renal hyperparathyroidism. Leaving aside the "pituitary" features—obesity with distended striae and hyperglycemia, the case fits into a group which one may term provisionally "renal hyperparathyroidism." The evidence is accumulating that long-standing renal disease is accompanied regularly by enlargement of the parathyroids and by increased functional activity of these glands. If there are still many obscure points in the renal-parathyroid relationship, the complexity is deepened by the fact that the patient presented all the characteristic clinical features of the Cushing syndrome. In view of the observations of other workers it was disappointing to the authors that their case showed neither a basophil adenoma nor hyalinization of the normal basophil elements. On the contrary, the basophils contained numerous well stained granules. Although the greater part of the gland was sectioned at necropsy, they cannot state with certainty that a small adenoma may not have been present. The rather massive ingrowth of cells into the posterior lobe, forming a fairly compact block of tissue, is of interest in connection with the view advanced by Cushing that such invasion is correlated with hypertension. They are not inclined to stress the finding of basophil cell masses in the pars nervosa as a possible factor in the production of hypertension or other symptoms. The posterior lobe cells and the basophils of the anterior lobe could

be sharply differentiated in their staining reactions, in that they contained no blue-staining granules. Since hyperplasia of the parathyroids and bone lesions characteristic of hyperparathyroidism are not characteristically associated with the Cushing syndrome, the authors incline to the view that the parathyroid enlargement and osteofibrosis of the bones in their case has resulted from the chronic renal disease rather than from some obscure pituitary stimulation. Further experimental studies, however, are needed to define more clearly the interrelation of pituitary, parathyroids and kidneys.

The Lipemia Curve Following Ether Anesthesia—Montanus and his co-workers made a study of the twenty-four hour lipemia curve of twelve patients subjected to various surgical operations under ether anesthesia. They did not observe any typical curve pattern or tendency when compared with the curves obtained in twelve patients operated on under other forms of anesthesia. In none of the twenty-four patients studied did the lipemia curve project significantly beyond an arbitrary normal fasting lipemia range.

Fractures in Children—Bisgard and Martenson discuss clinical and experimental studies relative to the influence of trauma on the epiphyseal cartilage. These cartilages, which are productive of all growth in the length of the long bones are responsive to many influences. Fractures in the long bones of children involve the epiphyseal cartilage in more than 10 per cent of cases. Deformities of clinical importance developed as a result of disturbances of growth in only six cases, or 25 per cent of the fractures in children less than 16 years of age.

These six cases represent only 12 per cent of fractures in which the epiphyseal cartilages were involved in the injury despite the roentgenologic evidence that in 50 per cent of these cases the injured epiphyseal cartilages fused prematurely or failed to resume completely normal growth activity. A child less than 16 years of age who sustains a fracture of a principal long bone is confronted with only a 25 per cent chance of having an important residual deformity, although he has a 20 per cent chance that the fracture will involve epiphyseal cartilage and if it does, a 50 per cent chance that an inconsequential disturbance of growth will result. Since deformities from abnormal growth appear months after a fracture has healed and continue to progress during the remainder of the period of growth every child with a fracture which involves the epiphyseal cartilage should be observed periodically for a year or more and his family warned of the possibility of this sequel. Another late complication is paralysis of the ulnar nerve, which develops as late as thirty years after a fracture involving the epicondyles of the humerus. In these cases the ulnar nerve becomes injured from impingement between the medial condyle and the olecranon as a result of the deviation deformity which results from malunion or from arrested growth from one of the epicondyles, particularly the external one. Infection, fixation and traumas are some of the factors, often unavoidable, that greatly increase the likelihood of disturbances of growth. The possibility of a disturbance of growth should be anticipated at the time of injury and the need of special consideration of the epiphyseal cartilage in the handling of fractures recognized.

Cellulitis of the Neck Requiring Tracheotomy—New cites five cases of cellulitis of the neck producing sufficient obstruction of the upper part of the respiratory tract to require tracheotomy. Three of these patients had a diffuse cellulitis and thyroiditis following infection of the upper part of the respiratory tract, one patient had exophthalmic goiter, thyroiditis and an abscess of one lobe and the isthmus of the thyroid, and the other patient had a diffuse cellulitis of the buttocks, a spreading cellulitis of both parotid regions and the neck, and pneumonia developed after a hysterectomy had been performed. Patients who have infections of the neck are treated with large, hot, moist dressings which should be changed every hour. If inflammation is present in the mouth or throat, hot irrigations also are used. If the patient is unable to take sufficient fluids by mouth, they are supplied through a Rehmann tube passed through the nose into the stomach. If edema of the larynx occurs, inhalations of steam are used and, in cases in which it is indicated, an oxygen tent is employed. Irradiation is of definite value in the treatment of certain infections of the neck. The parotitis associated with upper abdominal operations is greatly benefited and is some times cleared up by the use of radium packs if used immediately after the onset of the infection. Certain diffuse boardlike infections of the neck have been entirely cleared up without drainage by the use of roentgen therapy. Drainage of the phlegmon is performed by means of intravenous administration of sodium ethyl (1 methyl butyl) thiobarbiturate, except in cases in which there is partial obstruction of the respiratory tract, in which a spray of ethyl chloride is employed. For drainage of a phlegmon of the neck when the upper portion of the respiratory tract is partially obstructed, a small incision is made in the skin over the point at which the phlegmon is becoming localized and a curved hemostat is passed into the pocket and spread. A fairly stiff cigaret drainage tube, 0.75 cm in diameter, is inserted and sutured to the skin with silk. Tracheotomy should always be performed early whether the cause of the respiratory obstruction is infection or neoplasm.

Athletic Injuries of Knee Joint Excluding Cartilage Injuries W E Tucker —p 525

Chemical Diagnosis of Early Pregnancy—The test that Patterson describes requires at least 50 cc of early morning concentrated urine. The urine is tested for high acidity by treating a few drops of it with methyl red, and if acid to this indicator it is adjusted with alkali until it is no longer pink. A 50 cc sample is then heavily inoculated with *Bacillus coli* and incubated overnight. After incubation, while it is still warm, 0.5 Gm of sodium bisulfite is added. The specimen is shaken until the solid has dissolved completely and then it is allowed to stand for fifteen minutes. The partially decolorized urine is transferred to a 150 cc separatory funnel and extracted with two lots of 40 cc of ether. The combined ether extracts are washed with a little water and then well shaken with a 30 cc portion of 10 per cent sodium carbonate. The alkali layer having been discarded, this washing process is repeated until the carbonate layer is completely colorless. The ethereal solution is then again washed with distilled water, and when the layer of water has been drawn off the layer of ether is further extracted with two lots of 40 cc of tenth normal sodium hydroxide. After separation and rejection of the upper ethereal solution the combined alkali portions containing the theol are treated with 25 per cent sulfuric acid drop by drop until acid to congo red paper. This acidified aqueous solution is then extracted with two portions of 40 cc of pure "analytic" ether, after which the layers of ether are combined and washed with a little water. The ether extract is given another washing with 10 per cent sodium carbonate, and after the rejection of the alkali the remaining ether is freed from all trace of the alkaline carbonate by two more washings with distilled water. The final solution is transferred in two portions to a 50 cc transparent silica flask and the solvent is completely evaporated by immersing the flask in a large beaker of water previously heated to 70 C, the last traces of moisture are removed in vacuum by direct application of suction to the flask. The reagent used for the development of the color reaction of the dry residue consists of 36 parts of pure phenol with 56 parts of pure concentrated sulfuric acid (Cohen and Marrian). To obtain the color reaction 1 cc of reagent is added from the buret to the dry residue and the flask is immersed in a large water bath previously heated to about 70 C. By frequently rotating the flask the whole of the residue distributed round the sides is brought into the reagent, and the temperature of the bath is rapidly raised to boiling point and kept there for ten minutes. It is now cooled by holding the flask under a stream of tap water. While this cooling process is going on 1 cc of 5 per cent sulfuric acid is added slowly, the contents of the flask are kept moving in order to bring the somewhat syrupy reagent into a homogeneous solution with the dilute acid. The product, which is still yellowish

is then reheated in the boiling water bath for two and a half minutes. A positive reaction is obtained when the original color gradually changes over to pink or red, a negative when this change is entirely absent. Urines from sixty-five cases in which a pregnancy diagnosis was required have been examined by the test. In all except one case the result was in agreement with that of the Friedman reaction.

Changes Following Arsphenamine Medication—Russell describes three cases in which the administration of arsphenamines has been followed by the production in the central nervous system not only of perivascular and ring hemorrhages but also of perivascular nonhemorrhagic areas of necrosis and demyelination. In case 1 the demyelinated areas are infiltrated with phagocytes containing lipid granules, in case 2 there are also areas in which necrosis is unaccompanied by such infiltration, and in case 3 the nonhemorrhagic perivascular lesions are scanty and only of the noninfiltrated kind. The spinal cord was available for examination in cases 2 and 3. The white matter contained, in addition to hemorrhages, focal areas of degeneration and necrosis resembling early lesions in subacute combined degeneration. The suggestion that the nonhemorrhagic necroses represent a later stage of the hemorrhages is not supported by an examination of the three cases. The nonhemorrhagic foci were devoid of both red cells and hemosiderin, their presence in case 3, in which the terminal illness was extremely short, points to their production simultaneously with the hemorrhages. There were no transitions between the fresh hemorrhages and the anemic necroses. It is not denied that demyelination and aggregation of phagocytes take place at the centers of ring hemorrhages in the course of time, as has recently been described by Wolff. As he points out, however, red corpuscles persist in such areas, at any rate up to the eighth day after trauma. Again, from Baker's series and from the author's observations there is no evidence that anemic perivascular necrosis is a stage preceding hemorrhage. It appears more probable, from the longer survival periods in cases in which such necroses are conspicuous, that they represent a less severe form of damage to the tissues. They are, at any rate, an independent development. The perivascular distribution of the necroses and their association with fatty degeneration of the endothelium suggest that an increase of permeability has permitted the escape of some toxin into the surrounding tissues. The toxic factor in this encephalitis is unknown. It appears unlikely that arsenic as such is responsible, because chemical analysis has shown that the arsenic content of the brain in cases of arsphenamine encephalitis is lower than in cases in which death has been due to poisoning.

with inorganic arsenic. Moreover, hemorrhagic encephalitis is not a recognized complication of poisoning with inorganic arsenic. The effect produced by the arsphenamines may depend on the circumstance that the arsenic is administered in organic form. The incidence of hemorrhagic encephalitis seems to be independent of the size of the dose injected. It has frequently been suggested that the cerebral complications are due to the action of arsphenamine on syphilitic tissue—the so-called Herxheimer reaction. This explanation is, however, unacceptable, as the complication has been recorded in nonsyphilitic subjects. In case 2 there was no anatomic evidence of syphilis although a positive Wassermann reaction of the blood was obtained. It has also been suggested that the hemorrhagic encephalitis is due to sensitization. This possibility appears to deserve further attention. The resemblance between the histologic changes in case 1 and those that have been recorded as a rare complication of antirabic treatment may be significant when regarded from this angle, when it is remembered that the treatment consists of repeated injections of heterologous brain material. Finally the nonhemorrhagic lesions in case 1 resemble also those which occur in encephalomyelitis that may complicate vaccination, smallpox and measles. In none of these has the pathogenesis of encephalomyelitis been established, but the possibility that they are dependent on sensitization has been entertained on clinical grounds.

Antibactericidal Effect of Certain Serums and Exudates—From his studies of the blood serum of many common inflammatory conditions Hughes shows that all positive cases, that is, those in which a substance having an antibactericidal effect is present, are associated with some sort of reaction or inflammation and, when negative serums are found, the patients have either traumatic conditions, neoplasms or chronic diseases with little reaction. As regards temperature, the majority of the positive patients are febrile and most of the negative patients afebrile, but exceptions are present in both groups. Any generalization about the nature of the substance must account for its liberation by burns, high voltage roentgen therapy and various allergic conditions, as well as by bacterial disease. It is not therefore of bacterial origin nor is it histamine itself, since histamine injected subcutaneously does not liberate it. Two recent publications offer evidence that the substance may have other effects. Menkin showed that a toxin is present in the fluid from burns, in edematous fluid and in pleural effusions due to irritants, which toxin paralyzes the capillaries of the skin and increases their permeability to dyes present in the blood. Wilson and others have shown the presence of a substance in the edematous fluid of burns which is lethal to animals. The two papers agree on the heat stable nature of the substances concerned. The antibactericidal substance here described by the author resists heating to 60 C for two hours or even boiling. Wilson believes his toxin to be associated with the serum proteins, Menkin's is stated to pass through a semipermeable membrane. The antibactericidal substance will not pass through cellophane and is precipitated, at least in part, with the eglobulin fraction of the serum. There is rapid loss of activity *in vitro*. Its presence in so many different conditions raises the hope that it may be the common factor in inflammation and in the associated toxemia from whatever cause.

Ferrous Sulfate in Nutritional Anemia—The stable solution that Mackay and Jacob used in the treatment of nutritional anemia in twenty-six children consisted of 1½ grains (0.1 Gm) of ferrous sulfate one-fourth minim (0.015 cc.) of dilute hypophosphorous acid 15 grains (1 Gm) of dextrose and enough chloroform water to make 4 cc. The dextrose is

dissolved in some of the chloroform water and the dilute hypophosphorous acid is added. The ferrous sulfate is dissolved in some chloroform water and added to the dextrose solution and made up to volume with chloroform water. This mixture will keep for more than two months at room temperature without any precipitation. The mixture was given three times a day in 1 or 2 drachm (4 or 8 cc) doses. It was always begun gradually, the full dose being reached in from three to five days. Given in this way, it was always well tolerated and there were no complaints of loose stools or colic. After about four weeks' treatment the weekly rise in hemoglobin of the children receiving 9 grains (0.6 Gm) of ferrous sulfate daily averaged slightly higher than that of those receiving 4½ grains (0.3 Gm), but the figures do not entitle one to say that 9 grains was a more effective dose, especially as the average time taken to reach 80 per cent was about the same in the two groups. In spite of good response to treatment—a rise of about 1 per cent daily in the early weeks—the average time taken to reach 80 per cent hemoglobin was about fifty days. The data indicate the need for continuing steady treatment for an average period of about two months, and a good deal longer in some cases. The presence of an intercurrent infection nearly always necessitates more prolonged treatment. During an intercurrent illness there is considerably more likelihood of a rise in hemoglobin level if a ferrous salt is administered rather than a ferric salt, and the response to iron treatment shown by several children with severe infections was striking. Though for therapy a ferrous salt has great advantages, for prophylaxis on a wide scale the cheap and stable iron and ammonium citrate is effective and well tolerated.

Serologic Method to Verify the Specific Properties of Urine and Blood of Cancerous Patients M Aron —p 1403
Reaction Mechanism of Gastric Mucin C Bonorino Udaondo and H Zummo —p 1405
Reaction of Para Amino Phenyl Sulfamide (Sulfanilamide) in Purulent Meningitis with Streptococci and Accessorily with Meningococci R Martin and A Delaunay —p 1406
Rheumatism and Their Treatment J Le Calve —p 1409

Specific Properties of Urine and Blood of Cancerous Patients—Aron points out that in previous reports (see also tract in THE JOURNAL, Aug 11, 1934, p 450) he demonstrated the presence of a specific principle in the urine of cancerous patients. By combining the urine of cancerous patients with 95 per cent alcohol he was able to obtain a precipitate which, when suspended in physiologic solution of sodium chloride and injected into rabbits, produced a characteristic reaction in the adrenal cortex of the animals. The author decided to make this principle in the urine the basis of a serologic test. He found that the blood of rabbits and dogs that were treated for a time with the urinary extracts from cancerous patients acquired a property by which, when was injected into another animal, it immunized the latter against the same extract that otherwise produced the corticoadrenal reaction. Thus the specific substance in the urine of cancerous patients behaved like an antigen and stimulated the production of antibodies in the blood. The author obtains from a urinary extract, the so-called antigen, by alcoholic precipitation of the urine. Then he prepares the blood serum and in the antigen-serum mixture. Discussing the causes of error he stresses the importance of the careful cleansing of test tubes and the fact that inadequate centrifugation or dilution of the serum may lead to errors. In the interpretation of the reaction, two factors are essential: the first is a flocculation which seems to be related to the presence of an antigen and of specific antibodies, the second is an inhibiting action of the cancer serum on the nonspecific flocculation or precipitation. The question whether the method can serve as a basis for diagnosis must as yet be answered negatively. However, the method demonstrates a certain unity in cancerous conditions, which is opposed to the anatomic and histologic plurality presented by malignant tumors.

Action of Sulfanilamide in Meningitis—Martin and Delaunay, after reviewing the literature, stress the slight toxicity of sulfanilamide, pointing out that the toxic dose is from twenty to fifty times greater than the curative dose. The therapeutic efficacy of sulfanilamide impressed the authors especially in a case of purulent streptococcal meningitis. The patient, a boy aged 8, had an extremely severe meningitic action. Treatment with antimeningococcus serum proved effective. After the bacteriologic examination established the etiologic role of a hemolytic streptococcus, treatment with sulfanilamide was begun. Morning, noon and night the boy was given tablets of 0.5 Gm each by mouth. At first the daily dose of sulfanilamide was 1.5 Gm, but it was increased to 2 Gm and then to 3 Gm. Under the influence of this treatment, the extremely desperate case had a favorable outcome. The authors cite others who obtained favorable results with sulfanilamide in the treatment of streptococcal meningitis.

Exercise and Rest in Treatment of Pulmonary Tuberculosis in High Mountain Sanatorium Voule —p 921
Experiences with Hydrotherapy in Tuberculosis Deiss —p 924
Experiences with Salt Free Diet H Stocklin —p 926

Exercise and Rest in Pulmonary Tuberculosis—Voule directs attention to the fact that, as the result of the prolonged activity and rest cure of the patient's with pulmonary tuberculosis their respiratory and circulatory organs become weakened. Training to counteract this weakened condition should be instituted under the guidance of a physician as soon as possible. The author accomplished this aim by beginning work therapy early and, in suitable cases by means of light indi-

vidual gymnastics combined with massage. When the work therapy is begun, the rest periods should be gradually reduced so that, when the patient is discharged from the sanatorium, he requires at the most two hours of rest daily.

Experiences with Salt-Free Diet—Stocklin says that about 10 per cent of the 170 tuberculous patients at his sanatorium are generally treated with the salt-free diet. He differentiates between an absolute and a relative indication for this treatment. The salt-free diet is absolutely indicated in renal tuberculosis, particularly if it is bilateral and complicated with tuberculosis of the bladder. In these patients it produces favorable results because of its high vitamin content. Together with methylene blue medication, the salt-free diet produces such good results in these patients that they themselves desire to continue it. For a similar reason, namely, to protect the kidneys, the author employs the salt-free diet also when gold preparations are given for long periods and in larger doses. There may exist a relative indication for the salt-free diet in pulmonary tuberculosis. The author employs it chiefly to exert a new stimulus in cases in which the organism has become inured to climatic and other influences. He resorts to it mostly in patients with severe bilateral processes in whom collapse therapy is impossible and psychic stimulation is necessary. In these cases it is usually given only for a few weeks, but in many cases it actually does have an alternative effect and is continued for several months. However, from time to time the patients are put back on an ordinary diet. If the salt-free diet is suitably prepared, it is usually well tolerated.

Histogenesis of Nevose Tissues and of Melanotic Tumors P Maggio —p 417
Reflex Circulation of External and Internal Carotid Artery After Ligation of Primary Carotid Artery in Man B Simonetta —p 444

Histogenesis of Nevose Tissues and Melanotic Tumors—Maggio says that the melanoblasts are the cells concerned with the formation of melanin. They give a positive Bloch dopa reaction. Melanophores are the cells concerned with the transportation of melanin from melanoblasts to the skin. They give a negative Bloch dopa reaction. The origin of melanoblasts and melanotic tumors is not as yet clear. The author made microscopic studies in series of normal pigmented, pathologic pigmented and nonpigmented skin tissues and pigmented and nonpigmented tumors. He found that a displacement of epidermal cells to the dermis may take place in several physiologic and pathologic conditions of the skin. In the histogenesis of pigmented nevi the cells displaced from the epidermis suffer structural and protoplasmic changes up to a process of anaplasia into connective cells. The cells of blue nevi and those of the mongolian spots are connective melanoblasts. They are differentiated from epithelial melanoblasts and from common melanophores. Connective melanoblasts cannot be differentiated from melanophores on the basis of their morphology. Connective and epithelial melanoblasts in a process of anaplasia, as they are found in malignant melanotic tumors of connective or epithelial origin, can be differentiated from melanophores. The latter in both cases act as typical phagocytic histiocytes. The author found in two melanotic tumors (a sarcoma from a mesodermal nevus and an epithelioma from basal cells) that dermal as well as epithelial cells may form melanin and contain a specific oxidase of the type described by Bloch. He concludes that melanoblasts may originate in specially modified epithelial or dermal cells and that there are two main species of cutaneous nevi: those of connective and those of epithelial origin.

Intrajugular Injection in Adults C Canella —p 1873
Induced Pain of Nipple and of Areola as Sign of Pulmonary Tuberculosis M Mazzetti —p 1874
Jaundice After Operations on Stomach N Lagravinese —p 1879

Sign for Early Diagnosis of Pulmonary Tuberculosis—The sign described by Mazzetti consists in the production of more or less intense pain, which is elicited by pressure with the index finger on the nipple or the areola. The pain may

be elicited also by pressing the nipple or the areola between the thumb and index finger or by lateral traction of the nipple. When the nipple is moved aside and pressure is made on the subjacent intercostal space, pain is not produced or little pain is elicited. According to the author the pain is due to the development of viscerosensory reflexes, which originate in the parietal pleura near the tuberculous focus and also in the tuberculous areas of the lung. The sign is of practical value in early diagnosis of pulmonary tuberculosis, especially in the center or base of the lung. It is valuable also for determining the tuberculous lung in cases of hemoptysis in which it is necessary to establish an artificial pneumothorax or to administer drugs through the respiratory tract.

*Tuberculous Bacteremia. Investigation of Its Presence by Loewenstein's Method. I. Bosco—p. 1310

Tuberculous Bacteremia in Dermatoses—Bosco investigated the presence of tuberculous bacteremia, as determined by Loewenstein's method, in a group of seventy-five patients suffering from tuberculous and paratuberculous diseases, especially dermatosis. The research included direct microscopic examination of smears prepared with centrifugates of the blood of the patients and culturing of the centrifugates in Loewenstein's medium. Negative results were attained in all cases. In a case of tuberculous epididymitis in a patient suffering from grave pulmonary tuberculosis, smears from the sputum stained with Ziehl's method and cultures of it in Loewenstein's medium showed abundant tubercle bacilli. Yet there was no bacteremia. The results of the author conflict with those reported by Loewenstein as to the existence of tuberculous bacteremia in tuberculous and paratuberculous dermatosis. Loewenstein's method is of value in culturing tubercle bacilli. It does not show bacteremia in tuberculous and paratuberculous diseases regardless of the localization or intensity of the disease. The tuberculous nature of a disease of unknown etiology cannot be ascertained by the results of Loewenstein's method. It is advisable to accept with reserve the appearance of positive or uncertain results because the latter may be erroneously interpreted as to the nature and significance of the organisms found in the cultures especially in microcultures. The organisms are not forms of tubercle bacilli, avian tubercle bacilli, tuberculous filtrable virus or mutating types of tubercle bacilli. In all probability they are remains of avian tubercle bacilli which are contained in the egg used in the preparation of Loewenstein's culture medium. The results of Loewenstein's method, which are positive in spring and negative in winter, as reported in the literature, may depend on epidemic fluctuations of avian tuberculosis in either season.

Functional Systolic Murmur in Pulmonary Artery in Children—Diaz Nielsen states that in some children with a normal cardiovascular apparatus a functional systolic cardiovascular murmur can be heard by auscultation over the pulmonary artery in the second or third left intercostal space. The murmur does not propagate. Its duration and intensity vary with individual conditions, especially those which result in increasing the velocity of circulation. The murmur is different from pathologic murmurs. It originates in a predominant functional factor. The organic factor, although of lesser importance, has to exist in association with the functional one in order to cause the murmur. The author found the murmur in eleven children with normal cardiovascular apparatus. Tele-roentgenography was performed in eight cases and radioscopy in three cases. Electrocardiograms were taken in all cases.

The time of velocity of circulation was determined in all cases by the dehydrocholic acid test. The average velocity of circulation was eleven seconds in a group of normal children and nine seconds in those who had functional murmurs. The author found that the systolic functional murmur is directly related to the increased velocity of circulation. It originates in the existence of a narrow infundibulum of the pulmonary artery. The growth of children improves the organic condition related to the infundibular abnormality, this results in a diminution of the functional disorder and, in many cases, in permanent disappearance of the murmur.

*Animal Experiments on Wound Healing with Cod Liver Oil and the Effect of Its Components. W. Lohr and F. Unger—p. 405

Experimental Tumor Formation—Sauerbruch and Knacke were impressed with the fact that young cancer patients exhibited with astonishing frequency disturbances of the sexual function. This was not necessarily associated with anatomic defects such as infantilism, hypoplasia of the genitals, cryptorchidism or atrophy of the testicles, but more commonly with functional disturbances such as irregular menses, deficient libido, frigidity, sterility in the married state and impotence. They have assumed in their animal experiments that the loss of sexual glands affected not only the specific sex function but also functions of a more general kind, namely, those which exercise a stimulating and building up effect on cell life, cell structure and cell growth. They further assumed that the loss of sex function was in itself sufficient to distort the ordinary processes of wound healing and of inflammation so as to give rise to uncontrolled and irregular cell proliferation. They have therefore abstained from the use of irritating cancer-producing substances and resorted to light traumatization, such as inflicting small wounds and injecting lactic acid or small doses of cholesterol. Rats were chosen because these animals develop tumors spontaneously in only 0.5 per cent. One group of normal rats was subjected to superficial traumatization, while in another group in addition to the same type of trauma castration or parabiotic union was practiced. In the last group of eighty animals, eight developed tumors which on microscopic examination by Rossle and Hamperl proved to be malignant. Five of these were associated with metastases. Of the forty animals in the first group, only one developed a tumor and that without metastases. The authors conclude that diminution or loss of the sexual function is one of the general predisposing causes of tumor formation. They found further that splenectomy in animals and in human beings leads to a marked increase of gonadotropic substance in the urine. There apparently exists the same interrelationship in the secretory activity of the spleen and the pituitary as between the latter and the sex glands. Castration creates a condition that favors tumor formation. The frequency of neoplasms in older people is related to the loss of the sex function. It is possible that the effect of gonadotropic substance on the cell metabolism is an important factor in carcinogenesis. There exists an interrelationship in the secretory activity of the spleen, the pituitary and the sex glands.

Cod Liver Oil in Healing of Wounds—Lohr and Unger studied the effect of whole cod liver oil as well as of its single components, on healing of wounds in growing guinea pigs. A symmetrical defect in the skin of the animal, 1.8 cm. in diameter, was made on each side of the back, one lesion being used as a control while the other was subjected to the action of the substance studied. The rate of healing and the appearance of the lesion and of the resulting scar were used as criteria. As a result of some 500 experiments the authors conclude that cod liver oil is effective in accelerating the healing of a wound. The effect of the vehicles of the various ointments into which cod liver oil is incorporated in proper concentration is indi-

ferent They have found that both vitamins A and D exert a favorable influence on the healing of wounds The unsaturated fatty acids present in cod liver oil as glycerides in the saponifiable components of the oil are themselves capable of stimulating the healing of wounds They become even more effective in the presence of nonsaponifiable elements of the oil in which there are contained vitamins A and D Concentrations of vitamins higher than those present in the natural state in the cod liver oil retard rather than accelerate the healing of wounds The stimulating effect of the components of cod liver oil on the healing of wounds has a general besides the local action, as manifested by the behavior of the untreated lesion on the opposite side The authors regard the stimulating effect of the vitamins on the healing of wounds in the nature of a catalytic stimulant of oxidizing cell processes This was found to be true of the individual components of the cod liver oil as well as of the combined effect of the vitamins and of the unsaturated fatty acids

*Contributions to Experimental Agranulocytosis G Krauel —p 1245

Determination of Physiologic Span of Saturation of Organism with Vitamin C T Baumann —p 1246

Size of Erythrocytes—Freerksen criticizes the existing methods of the determination of the diameter of the erythrocytes He shows that the customary methods of the preliminary treatment and measurement are too diverse to insure comparable and exact results Moreover, in measuring the size it is usually considered sufficient to determine the mean diameter, which he demonstrates as unreliable Another reason why the usual measurements of erythrocytes are unreliable is that there is no normal or basic measure available to which the results can be compared Because of this there is a tendency to ascribe too great importance to factors that can be deduced from the physiologic-chemical peculiarities of the plasma in the case under consideration Thus the fluctuations in the mean diameter of the erythrocytes of patients with diabetes mellitus has been ascribed to the acidosis The author studied the problem of the size of the erythrocytes from the anatomic point of view He demonstrates that in healthy persons as well as in patients the size of the erythrocytes is dependent on the size of the pertaining normoblasts and that changes in the size of erythrocytes, which have been detected in certain disorders, are unreliable, because they are based on the inexact mean diameter He emphasizes that in searching for changes in the size of the erythrocytes in diseases of the erythropoietic apparatus it is necessary to consider also the quantitative conditions in the bone marrow

Experimental Agranulocytosis—Krauel reports the history of a man, aged 26, who was hospitalized with the typical symptoms of agranulocytosis Fever, chills, sore throat and difficulty in swallowing had developed after the patient had taken a tablet of aminopyrine The examination of the blood revealed an agranulocytosis The anamnesis revealed that six years previously the patient had been treated with large doses of aminopyrine, on account of acute articular rheumatism Since then there had been no recurrences of articular pains and the patient had used no medications until he took the tablet of aminopyrine After the agranulocytosis and all its complications had been completely counteracted by blood transfusion and other measures, it was decided to determine by a test whether the aminopyrine had really caused the agranulocytosis The patient was given by mouth 20 mg of aminopyrine that is, only the fifteenth part of the usual tablet (0.3 Gm) This small dose elicited a noticeable general reaction with fever, weakness and cyanosis The blood picture showed a temporary decrease in leukocytes but the differential blood picture revealed no essential changes Taking into consideration the attack of agranulocytosis and the reaction elicited by the small dose of aminopyrine the case corroborates the opinion that agranulocytosis may be regarded as an allergic or anaphylactic disorder The author stresses that the experimental production of an agranulocytosis involves dangers and may cause serious complications

*Menstrual Allergy G Singer —p 1273

Sprue and Vitamin Deficiency a Casuistic Contribution R Engel and Q Codas Thompson —p 1277

Menstrual Allergy—Singer of Vienna points out that in some women there regularly recur in the course of the menstrual cycle severe disturbances of the type of the exudative or angioneurotic diathesis The essential character of these periodic attacks corresponds to that of the allergic diathesis In addition to the individual predisposition, such substances as cholesterol and histamine, which during the menstrual cycle reach the blood in larger quantities, play a part as antigens However, another regularly existing factor is a usually acquired hepatic disorder The liver, which is nearly always involved in allergic disorders, has the central position among the causal factors of the allergic disturbances that are of menstrual origin The prophylaxis and therapy of the menstrual allergic attacks must take into consideration all processes that influence the function of the liver The author stresses dietetic measures, particularly the restriction of animal proteins and fats and a liberal provision with carbohydrates Further he recommends the use of Vichy or Karlsbad water and medication with dry peptone, from 0.5 to 1 Gm of which should be given one hour before each meal In addition to measures that influence the liver directly, he stresses the importance of regulating the gastro-intestinal tract and thus indirectly protecting the liver for instance, achylia and constipation should be counteracted The prophylactic treatment should be intensified during the premenstrual period Beginning with the fourth day before the onset of the menstruation, the patient should eat no meat at all, and the vegetable proteins likewise should be restricted If prodromal allergic symptoms appear, a bile acid preparation and concentrated sugar solutions are advisable These measures and thorough evacuation of the bowel will either prevent or reduce an allergic attack The author observed that, when the dietetic and medicinal measures were continued for several months, the predisposition to the allergic attacks was usually reduced so that eventually the attacks ceased entirely

Influence of Tryptophan and Histidine on Gastric Ulcer—Furih and Scholl state that in earlier studies they were able to corroborate the observations of Weiss, Aron and Holtzmann, namely that the cure of artificially produced gas-

tric ulcers can be accelerated by means of tryptophan. Of thirty-two large dogs in which gastric wounds had been produced by the excision of small areas of the mucosa, fifteen were treated with injections of tryptophan, two with histidine and one each with glutamic acid, aminoacetic acid and alanine. It was found that tryptophan greatly accelerates the healing process of the artificial wounds of the gastric mucosa. Of the two dogs that were treated with histidine, one gave a positive and one a negative result. The animals that were treated with the other substances gave either negative or doubtful results. The authors further investigated whether these substances exert an influence on true gastric ulcers, that is, on ulcers that were produced by the injection of histamine. After much experimentation, a suitable method was developed by which histamine injections elicited gastric ulcers in guinea-pigs. Whereas the animals that were treated only with histamine developed gastric ulcers, the simultaneous administration of tryptophan prevented the development of such ulcers. Histidine proved much less effective than tryptophan.

Gastroduodenal Perforation—Sosnyakov reports 121 cases of perforation of gastroduodenal ulcer observed in the third surgical clinic of the Leningrad Medical Institute since 1931. The perforations were localized in all their cases on the anterior wall of the stomach or the duodenum. They have noted one instance of perforation on the greater curvature and five in the cardiac region. Eighty-one of the cases occurred during spring and autumn. Only 4 per cent of their patients were women. History of ulcer was present in 72 per cent. Among twenty-seven necropsies on patients who had died of perforation, there were found nine instances (33 per cent) of multiple ulcers with a perforation of one of them. Absence of liver dulness was observed in 56.2 per cent, sudden onset of pain was exhibited in 95 per cent, boardlike rigidity of the abdominal wall in 92 per cent and localization of the pain under the xiphoid process or somewhat to the right in 90 per cent. Roentgenoscopy was resorted to in only two cases. Vomiting was present in 27.3 per cent. The peritoneal exudate in the first six hours of perforation is usually sterile. Here gastric resection is indicated, provided the general condition of the patient is satisfactory. After twelve hours the peritoneal exudate contains a mixed bacterial flora with the predominance of colon bacilli. Here simple and brief operative procedures are indicated. Perforation was closed by suture alone in twenty cases, while in ninety-eight (81 per cent) a gastro-enterostomy was added. The peritoneal exudate was removed with dry tampons. The mortality rate was 22.3 per cent. Of fifty-five cases followed up and examined roentgenoscopically, 71 per cent gave excellent, 21 per cent satisfactory and 8 per cent poor results. The author concludes that the lapse of time between the perforation and the operative intervention is the deciding factor in mortality. Simple suture of the perforation with or without gastro-enterostomy gives satisfactory immediate as well as late results.

 Salivary Convulsions J J H M Klessens—p 4566
 *Laboratory Rats as Source of Infection with Leptospira of Weils Disease G Korthof—p 471

Influence of Body Posture on Electrocardiogram—Eriksen made electrocardiographic tests on sixteen patients with heart disease and on forty-five persons without cardiac defects. The tests were made first while the persons were reclining and then while they were standing up. Three leads

were taken. The author discusses the changes that were observed after the patients stood up. The most frequent changes were enlargement of the P wave in the second and third leads, reduction of R₁, enlargement of R₂, deepening of S₁ and reduction of T in all leads. The author directs attention to the discordance, which exists in many cases, between the changes in the QRS complex and in the T wave, which disproves the suggestion that the changes in the T wave are caused by positional changes of the heart. He cites factors indicating that the reduction of the T wave in the second and third leads is the result of an inadequate blood supply of the heart muscle when the person is in the erect posture. This decrease was observed in healthy persons as well as in patients with cardiac defects and therefore is of no value in the diagnosis of myocardial disease. There were indications that the type of body structure has an influence on the electrocardiogram.

Laboratory Rats as Source of Infection with Weil's Disease—Korthof reports the history of a man, aged 21, who presented the symptoms of Weil's disease. The patient's serum showed agglutination with Leptospira, and animal experiments with the patient's urine revealed the presence of the leptospira of Weil's disease. The patient had not been in contact with wild rats but had taken care of white rats in the laboratory. Although he had not been bitten by the white rats, it was considered possible that he had been infected by them. A number of the several groups of rats that were kept at the laboratory were examined. The most simple and reliable method for the demonstration of the infection in the white rats proved to be the examination of the blood for agglutinins against the leptospira of Weil's disease. In the first group of rats the agglutination test proved positive, whereas in two other groups it gave negative results, that is, the first group of rats was evidently infected. For the demonstration of Leptospira, the culture on renal material proved more simple and reliable than the inoculation of guinea-pigs.

 Weltmann's Serum Coagulation in Pulmonary Tuberculosis J Sigurdson—p 977

Pregnancy in Adipose Primiparas—Møller-Christensen tabulates the results of his investigations in 242 adipose primiparas and 500 primiparas of normal weight. He finds that the overweight primipara and her fetus are threatened by far more frequent and more serious complications. He states that prophylaxis should be begun before pregnancy by reduction of weight under medical supervision, preferably only by diet and exercise, a possible thyroidin treatment to be administered by the physician with great care and with the possible pregnancy in mind. If pregnancy has begun, prophylaxis is to be continued by diet and exercise exclusively, the diet to be abundant in vitamins and minerals and to contain about 2,000 calories. The weight should be controlled at least once a week during the entire pregnancy, in the first four months of the period the weight should increase but slightly, in the last half of pregnancy, not to exceed 1,000 Gm in two weeks. Regular examinations of urine and blood pressure are a matter of course. Whenever in the last two months of pregnancy the fetal weight is estimated to be about 3,000 Gm, attempted medically induced premature labor is advocated. The author says that by Huch's method (injections of small doses of solution of posterior pituitary together with quinine by the mouth), which is safe for mother and child, premature delivery can be induced in about 60 per cent of the cases. When the method fails, nature must usually be allowed to take its course, and only as a last resort should dilation according to Hegar or Bossi be done followed by puncture of the membrane. In adipose primiparas with large fetuses cesarean section may be advisable if no contraindications for other reasons are present, but, as in all other operations in overweight women, there is greater risk in cesarean sections in these women.
